The internal study of the skull cavity is not beyond our powers, and when the cranial walls are perforated by gunshot or otherwise a suitable craniectomy is indicated. The sources of internal bleeding can be ascertained and arrested by ligation, pressure or otherwise, and at the same time foreign bodies may be taken away. In more chronic cases, abscesses may be located and opened and all this can be done, as many recent brain operations have shown, without unjustifiable risk to life. More could be added but time and place forbid. Thus in a few words I have sought to indicate something of the progressive nature of your art and show you what great changes are being gradually but surely wrought in surgery, and that by these the character of the military surgery of the future must be largely altered. You, as its servants, will be expected to know far more than your predecessors. You will be required to have a deeper knowledge of the modern doctrines of pathology and to comprehend their practical application in your every day work. All of these matters have been exhaustively presented to you by able teachers.

When you leave this school and enter upon your active duties, you will assume higher responsibilities than those which usually fall to young medical officers. In addition to the instruction which in civil life precedes the acquisition of your professional degree, you have been especially taught many details

which will affect your military life. You will thus be spared some of those hard lessons of laborious and dearly bought experience which have fallen to your predecessors. You now know to some extent, what is before you, what you have to do and how it is to be done. In a professional point of view, you have had exceptional opportunities. You have enjoyed time for reflection and have been able to weigh well the teachings of the civil school and under the supervision of your military professors to adjust your previously acquired information to the exigencies and changing phases of military life and I believe, moreover, that perhaps for some of you there may be a new function not yet covered by any paragraph of regulations. I mean a teaching function. I think that going hence, rightly having used your opportunities, you may be instrumental in disseminating the garnered experiences of many lives. You may become missionaries of military medical science. I pray God, that one day some great Apostle may issue from this school who may by practice and by precept, so spread its name and reputation that men shall turn and look hither with reverence.

Ah, graduates, young officers, I almost doubt whether you fully estimate the advantages of your position. You enter upon your professional life at a moment when the bright rays of advancement illuminate the whole horizon. We know and see enough to feel that a future which no man can foretell, is dawning upon our profession. Oh, that I could throw from my shoulders the burdens of the last forty years and be among you and with you and of you; for I see, and not darkly, that your corps has a glorious future, a future which it deserves and has earned in the past, by self sacrifice and conscientious devotion to duty.

As a result, great institutions, the Museum, the Library and now the Army Medical School have grown up, they have called forth the admiration of the professional world and stand as enduring moments to the zeal, industry and learning of the Department. In this good report of your corps you will share. Do more, contribute to its advancement. Be jealous of its good name. In every proper way, seek to further its interest. Especially let your professional work be earnest, persistent and well directed so that your names may not pass away. Do not live in vain. There was something noble in the last words of that good old surgeon "My lamp is almost extinguished, I hope that it has burned for the benefit of others."

Let such be your life purpose. Remember that you have a triple duty before you: As members of our noble profession, let suffering humanity be your care. As officers, serve faithfully and devotedly; thus honorably will you uphold the flag of your country. As physicians, officers and gentlemen, be ever true to the dear old medical Department of the Army of the United States.

Dr. Brinton's address was warmly applauded at its conclusion, and indeed during its progress the audience showed its interest in the speaker's words and responded to his humorous paragraphs with appreciative smiles.

Senator Hawley then delivered their certificates to the members of the graduating class in the order of their standing at the recent examinations on the subjects embraced in the curriculum. This order was not that in which the young men entered the service

in October last; for while they then stood: 1. J. T. Kilpatrick, 2. J. H. Stone, 3. I. W. Rand, 4. P. C. Fauntleroy, 5. J. S. Wilson, their standing at the close of the session was: 1. Stone, 2. Rand, 3. Fauntleroy, 4. Kilpatrick and 5. Wilson. Senator Hawley spoke in his usual easy but sympathetic and earnest manner. He remarked that he had been saved a deal of trouble by the previous speaker as it had been his intention to refer to the great advances in medicine and surgery that had been made during the past few years in order that he might congratulate the young officers upon having their lives before them or upon not having lived earlier. He reminded them that although they had completed their school life they were only beginning their course of study in the practical work of life. Progress is rapid in this age of the world, and earnest and constant study is required to enable one to keep up with its advance. Can anything be more wonderful than what has happened in recent years even in the life-time of many who are yet young enough to take a hand in the work? Here General Hawley took a rapid and humorous survey of progress in many fields relating to medicine and surgery from the first administration of ether as an anesthetic in the operating room of the Massachusetts Hospital to the shadow pictures produced by the Röntgen rays. He then referred to the altered and elevated position of the army medical officer as compared with his status during the Napoleonic wars. Out of the memory of his own war experiences he paid a high tribute to Dr. Francis Bacon and Dr. George C. Jarvis, both of the 7th Connecticut Volunteers, for the excellent sanitary condition and the low sick and mortality rates that prevailed in his regiment and brigade. These officers did good work in caring for the sick and wounded; but it was in preventing sickness, in protecting the men from insanitary conditions and preserving the fighting strength of the command at its maximum that the work of these officers was specially commendable. Senator Hawley then congratulated the student officers on having had the advantages of the Army Medical School and concluded by wishing them all success professionally and socially.

At the close of this address the audience broke up into groups and inspected the library and museum and the lecture room and laboratories of the school. In the evening there was a social gathering at the residence of Surgeon-General and Mrs. Sternberg, at which the members of the class had an opportunity of becoming acquainted with the medical officers of the Army and Navy stationed in or near the city and the ladies of their families. This reception constituted a pleasant close to their months of study and a social send-off to be remembered with pleasure in after years.

ORIGINAL ARTICLES.

THE TREATMENT OF RETRODEVIATIONS OF THE UTERUS.

Read before the Steuben County (Ind.) Medical Society, Aug. 23, 1895.

BY CHARLES N. SMITH, M.D.

GYNCOLOGIST TO ST. VINCENT HOSPITAL; FELLOW OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNCOLOGISTS.
TOLEDO, OHIO.

In the treatment of retrodeviation of the uterus, as in fact, in any abnormal condition, either medical or surgical, a thorough understanding of the etiology, pathology and complications is demanded in order

that the desired results may be obtained. Without this knowledge failure will, as in the past, attend our efforts in a lamentably large proportion of cases. I believe that the statement will stand unchallenged that, until recently, the treatment of retrodeviations was most unsatisfactory and unsuccessful and that the cause of such frequent failure was the attempt to treat all cases by a similar method, either without due regard to, or in ignorance of, their causes and possible complications.

For years, the vaginal tampon and pessaries, aside from certain plastic operations on the vagina and perineum, constituted our sole means for the correction of uterine displacements. It can not, therefore, be considered a cause for surprise that innumerable forms of pessaries, ingenious and otherwise, were employed in the vain and, as we now recognize it, unreasonable attempt to correct these displacements.

With the ever increasing experience in pelvic and abdominal surgery, naturally came a better knowledge of the complications so frequently associated with retrodeviations and it was readily seen how futile the wearing of a pessary must be in many cases and how dangerous in others.

Upon opening the abdomen in cases of retrodeviation, even with a movable fundus and seemingly without grave complications, we occasionally find one or both ovaries, with their accompanying tubes, prolapsed along the side of, or even behind, the uterus and attached to it by adhesions either slight or extensive. In the absence of adhesions between the fundus and the posterior wall of the cul-de-sac, such a uterus could be replaced by manipulation through the vagina. Such a replacement, having met the only then recognized requirement prior to the introduction of a pessary, would have been followed by the propping up of the uterus by the manipulator's favorite pessary.

We now realize, what he then did not, that the pressure and irritation of a pessary under such conditions may be productive of most serious results. Plastic lymph is poured out in increased quantity, adhesion follows adhesion, binding the displaced and distorted organs more firmly, pain becomes augmented and all symptoms, distressing before, now become so greatly aggravated as to make almost unbearable the sufferings of the invalided woman. Pelvic inflammations are rekindled and what was looked upon as an instrument of relief and even cure, has been the unsuspected cause of disastrous structural disease and most unnecessary suffering.

It is a matter for congratulation that, while abdominal surgery taught us how faulty and how frequently misapplied was the treatment by pessaries, it enabled us to evolve more correct and successful methods of treatment, so that now surgical procedures advantageously supplement the employment of pessaries. It is to be regretted, however, that from certain quarters we hear the use of pessaries unqualifiedly condemned and resort to surgical methods advised in all cases. Such a practice can not be considered other than an unnecessary and unjustifiable resort to surgery, for before surgical methods were employed, the most reliable statistics, as collected by Davenport, showed that at least 10 per cent. of all retrodeviations were absolutely cured by the use of pessaries, while an additional 15 per cent. were symptomatically cured, although the displacements remained after the wearing of pessaries was discontinued. The same class of cases and certainly as large a percentage of all can,

and should still be cured, absolutely or symptomatically, by pessaries, while surgery must be content in the attempt to cure the large percentage remaining.

Although there are some noted exceptions, I find the impression quite general among the gynecologists of the country that Davenport's statistics are too low and that considerably more than 25 per cent. of retrodeviations are absolutely or symptomatically cured by pessaries. I am well aware that personal impressions, unsubstantiated by statistics, can not be too closely relied upon, and yet I am satisfied that Davenport's statistics, to say the least, do not place the percentage of cures too high.

In addition to this 25 per cent., or more, who are cured by pessaries, there is a class of patients whose symptoms are nearly or entirely held in abeyance while wearing a pessary and who suffer little or no annoyance from its presence. Such patients frequently prefer the continuous and indefinite wearing of a pessary to a surgical operation, be it ever so simple and safe, and certainly should be granted the method of their choice. Such cases, however, must not be classed among the cured.

Nothing so forcefully illustrates the wide-spread dissatisfaction among the profession with this universal treatment by pessaries, as the eagerness with which Alexander's operation was adopted and put into practice. It was extensively employed in many cases, both suitable and unsuitable. Through ignorance as to its limited scope and the indications for its employment, or from a faulty technique, many failures resulted, made necessary, frequently, from the very nature of the cases in which it was unwarrantably applied. An operation should not be condemned because of failure, when wrongfully instituted. Alexander's operation has now been employed for a sufficient length of time to establish its worth and has certainly shown itself to be a beneficent procedure in properly selected cases. To be sure, the range of its applicability is limited, but such can be said of many measures in medicine and surgery. Alexander's operation meets the requirements in by far the great majority of those cases which are relieved by the use of a pessary but which relapse into their former annoying condition as soon as the pessary is removed.

The methods of Dudley and Wylie, consisting of an intra-peritoneal shortening of the round ligaments by folding them upon themselves, have not been extensively employed except by their originators and a limited number of other operators. They do not bid fair to prove successful rivals to hysterorrhaphy, the only other operation with which they can be compared. It would be manifestly unfair to compare them with Alexander's operation which does not necessitate opening the peritoneal cavity. As compared with hysterorrhaphy, the claim is made for these two methods that the uterus is held in place by its shortened normal ligaments, whereas in hysterorrhaphy an artificial or abnormal ligament is created and thus the former bring about a condition more nearly approaching the normal than does the latter. I believe, however, that these advantages are more fanciful than real.

Hysterorrhaphy, after somewhat numerous methods, is the only other surgical procedure for the cure of retrodeviations as yet worthy of extended consideration. This was advanced as a secondary or supplementary operation to be performed when some co-existing disease made necessary a celiotomy. Being

the only means applicable to many cases of retrodeviation and having rendered such excellent results when employed as a secondary operation, it was but natural that its performance as a primary operation should be strongly advocated. Some of my most gratifying results in abdominal surgery have followed the performance of hysterorrhaphy as a primary operation, the separation of adhesions to the uterus and its appendages being considered as but a step in the technique.

Hysterorrhaphy is indicated in a much larger proportion of cases than is Alexander's operation, as it is the only proper procedure when the retrodeviation is complicated by disease of the adnexa, or by adhesions between the uterus, the tubes or the ovaries and contiguous structures.

The method of hysterorrhaphy which I prefer and always employ is that of Kelly, in which the posterior surface of the fundus is stitched to the abdominal wall between the lower angle of the incision and the bladder. This method places the uterus in ante flexion, in which position it remains, freely movable, but prevented from tilting backward by the resulting adhesions. I have been able in every case but one in which I have performed this operation to subsequently demonstrate to the satisfaction of others, as well as of myself, the existence of a movable fundus. The only case where I have not been able to show this is that of a patient from Nebraska whom I have not seen since she left the hospital.

This question of a movable or fixed fundus after operation for the cure of retrodeviation has provoked a discussion which, seemingly, is not yet approaching a close. The opponents of hysterorrhaphy urge as a serious objection to its performance that it leaves the fundus fixed, in an abnormal position, to the abdominal wall. Such objection is fallacious, for a properly suspended uterus is not fixed like a ship tied to her wharf, but, like one at anchor, has free motion restricted within safe limits.

In 1894 I had occasion to open the abdomen of a young, unmarried woman for the removal of an inflamed and adherent tube and ovary. For a number of years she had suffered from a retrodeviation for which a pessary had been worn with but slight if any benefit. Advantage was taken of the open abdomen to suspend the uterus, which was done in the usual way. One year later it became necessary to reopen the abdomen for the removal of the remaining tube and ovary. The condition following the hysterorrhaphy was most interesting. Whereas, one year before, the uterus had been tied snugly against the abdominal wall, it was now simply anchored to it by an adhesion or, more correctly speaking, an additional ligament, one and one-fourth inches long, one-half an inch wide and somewhat thicker than a sheet of blotting paper. This ligament, all must admit, gave the uterus a possible range of motion from side to side of two inches, and in the direction of its axis, and from before backward, of over an inch. That uterus could not be called fixed, yet it was held in ante flexion and the patient was entirely relieved of the symptoms produced by the displacement.

I will not attempt to deny that hysterorrhaphy may be, and occasionally is, followed by a fixed fundus, but I hold that such fixation should be charged to the technique of the operator, and not to the operation *per se*. If the operator, following the earlier methods of ventro-fixation, freely scarifies the uterus and

stitches it broadly into the abdominal incision, the resulting adhesion will be broad, firm and practically unyielding. Naturally, the fundus will, in the great majority of cases, remain immovably fixed. On the other hand, if the uterus be scarified but slightly, or not at all, and be stitched to the abdominal wall below the incision so that the wound in the peritoneum does not, when sutured, come in contact with the uterus, the resulting adhesion will be but a narrow band or cord. This adhesion will possess sufficient strength to act, as do the normal uterine ligaments, as a guy to retain the uterus in a comparatively normal position against the bladder, allowing the intra-abdominal pressure to be exerted, as is naturally the case, on the posterior surface of the uterus.

It is surprising that some gynecologists persist in confounding the indications for Alexander's operation and hysterorrhaphy, and endeavor to compare the two as if they were rival methods. There should be no such comparisons nor thoughts of rivalry applied to these two operations, for each has its separate and distinct field of usefulness and is indicated under different conditions, while the value of one does not in the least detract from that of the other. In fact, in the application of pessaries, the performance of Alexander's operation and of hysterorrhaphy, we have three valuable and indispensable methods for the treatment of retrodeviations.

The majority of cases of retrodeviation are, unquestionably, post-puerperal in time of occurrence and are due to a subinvolution of the uterus, rendering it large and heavy, and to a similar condition of the relaxed uterine ligaments. Relaxation of the sacro-uterine ligaments plays a most important rôle, not in causing the displacement, but in allowing the cervix to slip forward and downward, bringing the uterus into the axis of the vagina. Laceration of the perineum is another important factor in the production of backward displacements, in that, during defecation, the posterior vaginal wall is bulged forward and the posterior lip of the cervix consequently dragged upon in a downward direction. This one fact should impress upon us the necessity for the repair of lacerations of the perineum prior to, or coincident with, the treatment of retrodeviations.

The dorsal recumbent posture, which the woman assumes after confinement, and to which she later so frequently resorts for relief from her distressing backache, favors a backward displacement, the force of gravity meeting with no resistance from the relaxed ligaments. In the upright posture a slight prolapse occurs, permitted by the relaxation of the tissues, and with the prolapse, a straightening of the natural anterior curve of the uterus takes place. A full bladder adds its pressure as a displacing force, the fundus uteri is pushed backward, completing the displacement, and the intestines, crowding down in front of the fundus, tend to retain the weakened organ in its displaced position. The tonicities of the uterine walls and its ligaments being greatly impaired, with all forces acting to maintain the uterus in its unnatural position, it is far from probable that the organ will ever, unaided, regain its natural position. Circulatory disturbances in the nature of passive congestion follow, resulting in an impairment of nutritive processes. Chronic endometritis and metritis soon become engrafted upon such a uterus, and add their detrimental influences as complications of the displacement.

Under such circumstances as the above, pregnancy seldom occurs, the woman proving relatively sterile. When pregnancy does take place, abortion is apt to follow before the fourth month, owing to the pressure of the enlarging uterus against the sacrum and its promontory, under which it may become more or less firmly wedged.

The frequent repetition of abortion in a retrodeviated uterus may be the cause of subinvolution, the conditions of cause and effect, as described above, being reversed, the displacement causing the subinvolution, through frequent abortions, rather than the subinvolution causing the displacement.

When subinvolution, with its attendant endometritis and metritis, is associated with backward displacement, either as cause or effect, the efforts directed toward the cure of the displacement resolve themselves largely into means for the relief of the complications. Uterine inflammation must be subdued, circulation restored to its normal activity, involution secured and the displacement rectified. For quick results, nothing is so satisfactory as a thorough instrumental dilation of the uterus, aseptic curettage with the sharp instrument, followed by gauze packing and drainage. The curettage is to be followed, at the same sitting, by one of two procedures, either manual replacement of the uterus with maintenance of position by wool tampons, to be later followed by a pessary, or performance of either Alexander's operation or hysterorrhaphy.

We often find that the cure of the complications by the curettage and the maintenance of the uterus in position for a few months, by means of a pessary, is sufficient to secure permanent restoration of the uterus to its normal position. Where this treatment fails, in that the pessary can not be removed without subsequent return of the uterus to its abnormal position, with its attendant symptoms, Alexander's operation is indicated. It is, possibly, advisable to treat all of this class of cases as above mentioned, but as the curettage necessitates anesthesia, advantage may be taken of the latter to at once perform Alexander's operation, and thus save the patient the many annoyances attendant upon the wearing of a pessary. A second resort to anesthesia for the performance of the operation made necessary by the failure of the pessary, may then be forestalled. Many a woman with a retrodeviation is allowed to suffer unnecessarily without receiving the attention from her physician which her condition requires. Her importunate demands are satisfied, from time to time, by the insertion of a pessary which, while it may temporarily relieve, does not cure. Alexander's operation is safe, and ordinarily gives satisfactory results, and such a woman is entitled to its benefits if she so elects.

When, however, adhesions have formed between the uterus or its appendages and the walls of Douglas' cul-de-sac, or when the appendages are diseased, especially if there be a history of salpingitis and pelvic peritonitis, neither pessaries nor Alexander's operation will meet the requirements. Nothing will answer but hysterorrhaphy with separation of all adhesions by the fingers within the abdomen.

The constant weight of the heavy uterus, causing irritation by pressure and friction between the opposed peritoneal surfaces, is frequently a cause of adhesions between the uterus and the posterior wall of the cul-de-sac. In a long-standing retrodeviation the tubes and ovaries, by the traction of the uterus, are dragged

backward and downward into the lateral portions of the cul-de-sac, where, subject to pressure, irritation and congestion, they are liable to fixation by an outpouring of plastic lymph. Salpingitis and pelvic peritonitis complicate many cases of retrodeviation and are, without doubt, responsible for the presence of adhesions in the majority of cases. It is the presence of the adhesions, fixing the uterus or the appendages, or both, which renders futile and even dangerous the wearing of a pessary and contraindicates Alexander's operation.

Without entering into a consideration of the recently advocated vaginal methods of operating for retrodeviations, I will offer the following conclusions:

1. In simple, uncomplicated retrodeviations, producing symptoms, pessaries should first be employed, to be followed, in the event of failure, by Alexander's operation.

2. In movable retrodeviations with healthy appendages but complicated by mild subinvolution, endometritis and metritis, Alexander's operation, preceded by curettage, is indicated. Curettage and pessaries may cure a limited number of this class.

3. In retrodeviations complicated by marked subinvolution, endometritis and metritis, or by tubal or ovarian disease, or by adhesions, hysterorrhaphy, preceded by curettage, is the only method permissible.

ELECTRICITY IN THE TREATMENT OF FIBROIDS OF THE UTERUS.

BY FRANKLIN H. MARTIN, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; SURGEON TO WOMAN'S HOSPITAL.

CURRENT.

In the treatment of fibroids of the uterus by electricity the direct current, or what is more commonly known as the galvanic current, is the form of electricity almost invariably employed. The maximum strength of current employed, 250 milliamperes, or one-fourth of one ampere, requires an apparatus which will possess an electro-motive force of 30 to 40 volts. The amount of voltage required varies in different cases with the varying resistance of the electrodes and the tissues of the uterus and abdominal wall through which the current must act. This resistance may be from 60 to 300 ohms. This deviating resistance is accounted for by the use of different kinds of electrodes and the variation in the resistance of the same tissues in different individuals.

APPARATUS.

The direct current may be generated for medical uses from *a*, primary batteries, *b*, from dynamos of the non-alternating or non-interrupting variety employed for incandescent street or house lighting and *c*, storage or secondary batteries.

PRIMARY BATTERY.

There are several distinct forms of primary cells employed by gynecologists in the treatment of fibroids:

Portable Battery. The old reliable portable battery is the one with zinc and carbon elements excited by a fluid of sulphuric acid and bichromate of potassium in water in cells of glass, or better, hard rubber. The voltage of each of these cells when freshly charged is about 2 volts. Therefore a battery of this description of about 18 cells properly connected makes a very suitable portable battery for the treatment of fibroids.

There are several so-called dry-cell batteries of secret construction which appeal to one on superficial

observation, because of the claims of their inventors, of cleanliness, durability, and freedom from objectionable fluids. All such batteries should be looked upon with suspicion, until they have proved themselves capable of furnishing an electro-motive force of from 30 to 40 volts for periods of five to ten minutes, several times a day for several months, otherwise the cost of recharging makes them too expensive.

Office Batteries.—For office battery where portability is not required, the Law cell, the improved Le Clanche, the Diamond Carbon, or cells of similar construction should be employed. They should be attached to a selective switchboard of such a construction that any portion of the battery may be employed at will. These cells may be placed in an adjoining closet or cellar and connected with the switchboard by a cable of wire, or they may be placed in a cabinet beneath the switchboard. As these cells have an average voltage of one or one and a quarter volts each, a battery of about 40 cells should be selected.

Street Wire Current.—One of the most satisfactory office fixtures for electricity is a connection from an incandescent lighting system of the uninterrupted or non-alternating variety reduced by some safe form of rheostat. One of the simplest rheostats is the McIntosh (Fig. 1). It is compact, easily comprehended and regulates the current in gradations from zero to the full strength of the street current, and reverse, without the slightest possibility of a break. A fuse box is also connected with this rheostat which will burn out and disconnect the current from the patient in case of an accidental dangerous increase of the electricity from any unlooked for source.

Storage batteries may be used as a source of electricity for gynecologic practice. However, as they are not economical and wherever they can be used to advantage they must be near some other source of electricity, it is obvious that one would seldom select this form of battery.

MILLIAMPERE METER.

To employ galvanism in gynecologic practice without a milliampere meter is criminal. There are three reasons for this: 1, because the resistance through the abdominal walls is so small and variable, that no one, no matter how experienced, can even approximately estimate the amperage of a current by the number of cells employed. 2, because of the powerful current often required in this kind of work, a dangerous dose might easily be given, and 3, because of inaccuracy in recording cases.

A milliampere meter should be selected which has two readings: One scale reading to 500 milliamperes and one reading to 50 milliamperes. This presupposes in reality a double instrument. By changing a switch either reading may be selected without the necessity of changing the connections.

The best milliampere meter I am acquainted with is the Weston. It is reliable, convenient, double reading, dead beat, and can be used in any position on a level without regard to the poles of the earth. The principal objection to this instrument for general use is its expense (Fig. 2).

An instrument which I have employed more than any other in my work outside of the office is the McIntosh instrument (Fig. 3). It is of the galvanometer type and much cheaper than the Weston. It is approximately correct, and barring the fact that it must be carefully adjusted to the polarity of the earth, be-

fore each using, and that the indicator is not dead beat, it is a very satisfactory instrument. It has a double reading; is made in two sizes, one large for office use and one small for portable purposes.

ELECTRODES.

In describing electrodes for use in the treatment of fibroid tumors I will limit my description to those which I actually employ in my own work and leave the innumerable confusing curiosities which adorn the ordinary instrument catalogues unmentioned.

Abdominal electrodes in use by me are of two kinds according to the dose required. When a current of less than 50 milliamperes is employed a large sponge, a large felt or a large spongio-pyoline instrument may be employed. These electrodes should be not less than six by eight inches of an oval shape. They should be thoroughly washed in warm water before using, and all surplus water squeezed out before the application is made. For a current above 50 milliamperes a clay electrode or the author's membranous

For internal electrodes I employ intrauterine, vaginal and rectal instruments.

The intrauterine electrodes are of two varieties; flexible concentration and soft copper.

The flexible concentration consists of platinum wire wound spirally over soft copper for varying distances tipped with hard rubber, and the portion of the instrument not active, is covered with some insulating material as rubber or linen covered with shellac. These instruments may be made of any diameter. I have them in sets of two, three and five millimeters in diameter respectively. The active surface which I ordinarily employ is four square centimeters (Fig. 5). In knowing accurately the active surface of an electrode, one can estimate more definitely the particular effect to be expected from a known current. This will be explained more comprehensively when we consider treatment technique.

Soft copper electrodes are employed in order that the uterine mucous membrane and deeper tissues may become infiltrated by cataphoresis with the salts of

FIGURE 1.

abdominal electrode should be employed. These being the only instruments which I have found in my experience which will uniformly distribute the current and prevent burning of the skin in spots.

The clay electrode is the cheapest form of the two. If made as recommended by Goelet, wrapped in cheese cloth with a rubber back it is comparatively clean and makes a suitable instrument where efficiency and economy alone is desirable. It is constructed of potter's clay of the consistency of putty molded into a cake, about eight by six inches in diameter by one inch in thickness.

The membranous abdominal electrode devised by the writer, is a water electrode, the cavity of the disk holding the water being covered with animal membrane, the membrane furnishing the surface of contact (Fig. 4). This instrument when filled with warm water makes an ideal electrode. It is cleanly, its temperature is easily regulated and it diffuses the current perfectly.

copper produced by a combination of tissue and copper electrolysis, which occurs at the positive pole. I have these electrodes made in sets of three instruments, each instrument having an electrode of different caliber on either end (Fig. 6). This makes six diameters—2, 4, 6, 8, 10 and 12 millimeters. The length of each electrode surface is six inches. The portion of the staff not employed in the uterine canal is insulated with a loose rubber muff.

Vaginal electrode.—I employ an instrument for this purpose like the one shown in Fig. 7. It has an active surface of about sixteen square centimeters, the staff of it being insulated with hard rubber over a copper core. The instrument is about six inches long and about three-quarters of an inch in diameter.

Rectal electrode.—I employ a long bulbous-pointed instrument about four inches long and one-half inch in diameter for a rectal electrode. The insulated portion has a metal surface of about ten square centimeters. The staff is insulated with hard rubber.

Effects of Galvanism on Living Tissues.—Fortunately the effects of electricity upon living tissues has been so thoroughly studied, clinically and experimentally, in the last few years that we are in a position to make some pretty definite statements about its

FIGURE 2.

action. These studies, too, have not been limited to the living tissues, but have been carried into the chemic, physiologic and bacteriologic laboratories to such an extent that we have many experimental proofs

Effect on Sensibility.—The positive pole or anode acts as a sedative while the negative pole acts as a cathode. This effect on the sensory nerves is called the electro-tonic effect and the two effects are expressed as the anelectro-tonic effect (sedative) and the catelectro-tonic effect (irritant). The use of electricity

FIGURE 4.

in gynecology with its employment of large doses has abundantly demonstrated to me the electro-tonic effect of galvanism.

Effect on Blood Vessels.—The positive pole con-

FIGURE 8.

which have proved true several former theories and exploded many others.

In applying galvanism to the tissues of the body the employment of two electrodes is necessary. In applying electricity to fibroids of the uterus the internal electrode is usually termed the active pole while the external one is called the passive pole. We speak, therefore, of three kinds of effects from the application of the current in this manner: Polar effects, inter-polar effects and general effects.

The polar effects differ materially with the pole employed. In several respects the effects at the two poles are diametrically opposed.

tracts blood vessels in its immediate neighborhood while the negative pole dilates them. These vaso-constrictor and vaso-dilator effects are easily demonstrated.

Chemical Reaction.—The result of tissue electrolysis between the poles produces an accumulation of alkaline elements at the negative pole and acid elements at the positive pole. This results in an acid reaction obtaining at the positive pole and an alkaline reaction at the negative pole. If the electrolysis is persisted in with a powerful dose these polar accumulations become caustic acids and caustic alkalies respectively.

Effect on Tissue.—The acid accumulation at the

positive pole when it becomes sufficiently concentrated from the effect of a strong dose coagulates the soft tissues and renders them for a short distance from the pole hard and dry. On the other hand the alkaline accumulation at the negative pole when strongly concentrated by a strong dose of electricity, dissolves the tissues and liquifies in the same manner as does caustic alkalies.

Effect on Pathogenic Microbes.—A zone of uterine tissue around the positive pole of a depth varying from a fraction of a millimeter to one or two millimeters according to whether the dose of current is small or great is rendered bacteriologically sterile by the employment of the galvanic current. This effect according to experiments made by Gautier, Apostoli, Enrico Burei, Vittorio Frascani and others, is not due to the electricity direct but rather to the chemie changes occurring around the positive pole as the result of electrolysis. For instance, if a copper electrode is employed oxychlorid of copper is formed as the result of a combination between the electrolyzed tissues and copper. This chemie combination is an active germ destroyer and in solution it is driven by cataphoresis into the tissues to a considerable distance, carrying its antiseptic properties with it. There is scarcely any antiseptic effect at the negative pole.

INTERPOLAR EFFECTS.

While it is easy to demonstrate polar action it is not an easy matter to make an ocular demonstration of the interpolar effects of the galvanic current on living tissues.

From experience in the employment of this current on living healthy and pathologic tissue, experience of many earnest investigators extending over a period now of several years, we are convinced that evidence enough has accumulated to justify us in saying that the following definite effects occur in tissues so acted upon: 1, interpolar electrolysis, 2, stimulation of trophic nerves, 3, cataphoric action.

Interpolar Electrolysis undoubtedly occurs between the poles as well as at the metal poles themselves. When such electrolysis occurs in a fibroid uterus it is easy to account for the reduction in size of that growth. When the molecules of weaker tenacity in such tissues become decomposed into their constituent elements oxygen, hydrogen, carbon, etc., these elements, as gas or solid particles, immediately on their release become foreign substances. While seeking for new combinations some of them are taken into some of the many absorbents traversing the tissues and are carried out of the system. Others form new combinations with free elements in the tissues, or with the decomposed material of the electrodes, or fluids surrounding the electrodes on the surface, and still others are liberated at the poles as solids or gases.

Stimulation of Trophic Nerves.—While the electrolytic effect of the current may account for reduction or absorption of growths, I believe that this result is materially hastened by powerful stimulation of the trophic apparatus of the uterus by electricity. We are forced to believe this by the fact that the general nutrition and functional activity of all the organs, any way coming under the influence of the current, are markedly improved.

The Cataphoric Action of the Galvanic Current.—This is the property of a current of electricity which enables it to push or conduct fluids in bulk through membranous or porous conductors in the direction of

the current flow, from the positive toward the negative pole. This is also called electrical cataphoresis. Fluids near or on the positive pole, either simple or holding in solution drugs or chemicals, will be driven into the living tissues when living tissues are made a portion of the conductor. So that the tissues of the uterus may become impregnated with any drug which can be dissolved in water by surrounding an intra-uterine positive electrode with a film of cotton saturated with the particular fluid and causing a current to traverse the tissues.

The general effect of galvanism upon the tissues is that of a powerful tonic. Irregular practitioners, for a large number of years, employed electricity in some form successfully because of its power to stimulate general nutrition. It mattered but little what form of electricity was employed, or where it was applied so long as some portion of the sick man became a part of an electric circuit; it was sure to stimulate him, improve his nutrition and make him feel a stronger man. The powerful doses employed in the use of galvanism in the treatment of fibroids exaggerates this tonic effect of electricity to such a degree that many physicians have endeavored to attribute to it all the credit for improvement of fibroids under electricity.

Summary of Effects of Galvanism in the Treatment of Fibroids of the Uterus.

Polar Action: *Negative Pole* a. Irritant; b. Vaso-dilator; c. Alkaline; d. Liquifies tissues; e. Antiseptic (slightly). *Positive Pole* a. Sedative; b. Vaso-constrictor; c. Acid; d. Coagulates tissues; e. Antiseptic (powerful).

Interpolar action: Electrolysis and trophic stimulation.

General Action: Powerful tonic.

THE APPLICATION OF GALVANISM TO THE TREATMENT OF FIBROIDS.

What is the present status of the treatment of these benign tumors by electricity? With the brilliant results of present surgery as a competitor, one must have considerable courage to offer electricity as a remedy at all in these cases. But as an abdominal surgeon with at least average success, and at the same time as one who interested himself early and enthusiastically in the much-lauded Apostoli treatment when it made its *début* in this country, I am constrained by sense of justice, knowing well both sides, to say that in the interest of those who have fibroids of the uterus, that the knife, even in these times of brilliant successes in surgery, is used too often and electricity too little. If a brilliant hysterectomy with its average mortality of 5 per cent. ended the matter, and the 95 per cent. recovering gained health immediately, we could have but little to say. When, however, we must reckon on the months of nervous suffering with which the majority of these patients who have their tumors removed have to contend, after this operation, before they receive the well-earned cure, and when we take into consideration the not large but certain percentage of fistulas, hernias and other well-known distressing sequelæ following operations, and last but not least when we remember the grim specter of that 5 or 10 per cent. who did not recover, are we not justified if we have a conscience (especially when we realize that a fibroid of the uterus when left alone seldom proves fatal) in giving our patients the benefit of a treatment, which seldom fails to *relieve* these cases, and while it frequently fails to cure, *never kills* and *never*

does harm and never interferes with the success of an operation, if it in the end fails to cure?

Experience in the treatment of fibroids of the uterus by electricity has taught me how to select my cases, when to encourage a patient to receive electricity and when to encourage her to select an operation. Rules which I have formulated and allowed to influence me but not control me (because I make frequent exceptions to them in individual cases) are as follows:

WHEN. ELECTRICITY IS SPECIALLY INDICATED.

1. In bleeding fibroids in women approaching the menopause.
2. In all inoperable cases.
3. In incipient fibroids in women over 40 years of age.
4. In all bleeding fibroids of the smooth interstitial variety which have no symptoms but hemorrhage.
5. In all cases (not accompanied by pelvic pus accumulation) which refuse to have an operation.

TECHNIQUE OF TREATMENT OF TYPICAL CASES.

A typical case for the successful treatment of fibroids of the uterus by electricity is that of the interstitial variety, in which the new tissue is uniformly distributed throughout the uterus, enlarging it to a symmetrical tumor of varying sizes, and proportionately expanding the uterine canal. These cases are almost invariably of the hemorrhagic variety because of the expansion of the uterine mucous membrane. The hemorrhage occurs as an exaggerated menstrual flow. These tumors vary in size from a growth the size of one's fist to a tumor filling the abdomen with a uterine canal many inches deep. Those not exceeding six to eight inches in length and three to four inches in lateral diameter are the ones in which electricity accomplishes the best results.

METHOD OF PROCEDURE.

We seek in these cases, *a*, to transmit through these tumors, for its electrolytic effect, as strong a current of galvanism as the patient will bear, without severe discomfort, and, at the same time, not to severely cauterize the tissue at the poles. *b*, We seek to get acid accumulation at the positive pole located in the uterus, of sufficient density to coagulate the tissues and thus lessen the bleeding. *c*, This same acid at the positive pole we expect too combine with the copper of the electrode and form salts, which salts in solution by the cataphoric action of the current will be driven into the uterine tissues, immediately surrounding the electrode, and as a styptic materially aid in curing excessive flow. *d*, We seek further to obtain the powerful antiseptic effect as the result of chemic changes occurring around the internal electrode, in order to cure the endometritis which almost invariably exists as a painful accompaniment of fibroids.

After an antiseptic vaginal douche the patient to be treated is placed upon a table on her back with her buttocks drawn well to the edge and feet supported by stirrups. The size, shape and direction of the uterine canal is obtained by the use of large, flexible sounds. A large copper electrode then, of suitable diameter, is properly shaped and passed to the bottom of the uterine canal, and the vaginal portion insulated with the rubber muff. This electrode is then attached to the positive terminal of the battery. A clay, or the writer's membranous abdominal electrode, is next

passed under the loose clothing and placed on the abdomen and then attached to the negative pole of the battery.

The current is now gradually turned on while the milliamperere meter is carefully watched and the features of the patient are closely scanned for signs of pain, until the current reaches 100 to 150 or even 200 milliamperes, according to the tolerance of the patient and the size of the active internal electrode. If the active electrode is of the ordinary diameter of from 3 to 5 millimeters, a current strength of 100 milliamperes can be used safely in any particular case for every two inches in length of this electrode which is active. *To be more accurate, the current should not exceed in strength 25 milliamperes for each square centimeter of active surface of the internal electrode.*

So that in the general run of cases one can safely give the patient as strong a current as she will bear without danger of producing excessive cauterization at the active pole. This will vary from 100 to 200 milliamperes. The time of each treatment should be five minutes for the maximum current employed. The treatment should be given as often as every second day. Except in cases of continuous flowing, the treatments are best given between the menstrual periods.

These cases begin to improve almost immediately. The first improvement is in relief of neuralgic and so-called pressure pain. In a few days they find that their general strength is improved. Reflex disturbances such as stomach irritation, palpitation of the heart, occipital headache and backache will be relieved. The patient will begin to eat and sleep naturally. There is a general feeling of well being engendered. In a few days the leucorrhea or purulent discharge from the endometrium will diminish. As the patient arrives near the menstrual period, she finds that the old premenstrual aches are not present, the old despondency is absent. If the treatment has been sufficiently active the menstrual flow will arrive without pain frequently. Occasionally, the first month the flowing is fully as free as usual, although frequently it is much less. If the treatment is continued for two or three months these patients will begin to maintain that they feel perfectly well. All the old distressing symptoms will very often disappear entirely, they will gain flesh and the uterine discharge will become normal. While the tumor will still be apparent to the physician's examination it will almost invariably be found to be much diminished in size. When the time arrives in the treatment that these patients are symptomatically cured, that is when they feel no symptoms, I usually discharge them. I always inform them that the tumor has not disappeared, and that sometime it may again give them the old difficulties. As long as they are free from these they may be satisfied that the tumor is not growing—on the contrary decreasing in size. However, if the old symptoms begin to return I instruct them to seek relief again in the electricity.

The above treatment applies to the typical bleeding fibroids of interstitial variety.

Where the uterus is large and the canal is deep, it is necessary sometimes to attack the mucous membrane by piecemeal, in order to get sufficient concentration with the dose tolerated to accomplish sufficient changes in the endometrium to check hemorrhage. The concentration necessary should approximate 25

milliamperes for each square centimeter of the electrode in contact with the mucous membrane. For example, if a patient will only bear a current of 100 milliamperes, one should select an electrode of copper or zinc or platinum with a diameter of proper dimensions, insulated to all but 4 square centimeters of its distal end. The depth of the canal is measured. Then commencing with the distal end of the cavity, the exposed active surface of the electrode is made to cover in successive treatments its whole surface. By doing this the whole mucous membrane is acted upon uniformly without employing at any time a larger dose than 100 milliamperes.

INOPERABLE AND COMPLICATED CASES.

The cases which are referred to the writer for electrical treatment, in these days when active surgery offers such a large percentage of recoveries from hysterectomies, are for the most part complicated cases, which the ordinary surgeon shuns.

One complication which frequently induces the surgeon to shift the responsibility of these cases, is that of severe purulent metritis and endometritis, accompanied frequently with discharges of gangrenous masses from submucous fibroids, all accompanied with much pain, more or less hemorrhage, and with the discharges inclined to be very offensive. The patients are usually poorly nourished, with white and waxy skin in consequence of septic absorptions. When they reach this stage they are frequently pronounced malignant. The outlook for an operation certainly is not flattering.

Now the writer has been honored frequently by having such cases sent to him for electrical treatment, by different friends of his who are conscientious surgeons.

What have we to deal with? Usually a tumor of large size extending to the navel. It is soft, with nodular masses projecting from its peritoneal surfaces. The cervix is soft and patulous, with a canal large and irregular. Sometimes a small nodular mass is presenting at the cervix. This is usually soft and easily broken down. The endometrium and all cavities from which masses have been projected or from which masses have sloughed away are infected and ulcerating, and emitting a discharge which rapidly becomes offensive. From the large mucous membrane periodic and irregular uterine discharges are occurring, serving to swell the already copious outpour.

The writer has treated by electricity and symptomatically cured several of these cases in which a diagnosis of cancer had been made by men of more than ordinary talent.

I prefer, when it is practicable, to dilate the canals carefully in these cases, and remove with a dull curette the superficial debris before beginning the electricity.

I then select one of the largest copper electrodes which can be inserted and make it the active positive pole, inserting it to the bottom of the canal with its whole surface uninsulated. With the abdominal electrode in place, a current is gradually turned on until a strength of 200 milliamperes is reached, or the maximum amount under that strength that the patient will tolerate.

These treatments should be given every other day. Antiseptic douches should be employed night and morning.

These cases respond rapidly. The powerful antiseptic action on the mucous membrane makes itself

apparent by the decreased odor of the discharge. The passing and withdrawing of the electrode opens and provides free drainage for the secretions. The tissues become tanned by the salts of copper which are forced into them by cataphoresis, and the discharge of blood is lessened. The patient is toned by the general effect of electricity on her system. In a word, it is frequently marvelous what a transformation will take place in these apparently hopeless cases in a few weeks of judicious galvanic treatment.

While these cases are apparently hopeless, oftentimes when they are "given over" by the surgeon, they are frequently symptomatically cured by this simple remedy. The writer has a long list of such cases, and they constitute some of the most satisfactory work he has ever had placed to his credit.

INOPERABLE TUMORS TREATED BY OTHER THAN THE INTRAUTERINE METHOD.

There is a class of complicated cases of different kinds in which it is impossible, because of the contortions of the growth, to enter the uterine canal with an electrode. Occasionally the tumor has displaced the cervix so that it is drawn high in the vagina above the bladder, out of reach of finger or sound; while again it is drawn up posteriorly with the uterine canal forming an acute angle with the vagina. In all cases where it is impossible to reach the canal, if they are treated by electricity, it is necessary to employ it without the advantages of an intrauterine electrode.

Only in the most desperate cases, in which submitting to an operation is clearly suicidal, would one think of employing electricity as a means of treatment, when an intrauterine electrode was impossible. But it is in just these cases, with their distressing neuralgic and pressure symptoms, with dyspeptic complaints and bowel irritations, the result of reflex nerve disturbances, in which an operation is discouraged, that we find patients ready to catch at any straw.

In many of these cases I believe that electricity not only offers a straw, but a veritable lifeboat to their despairing bodies.

When an intrauterine electrode is not practicable, then we should employ some other form of internal electrode which will have the effect of causing the current of galvanism to pass directly through the largest portion of the tumor.

If the vagina is not distorted so but that a vaginal electrode may be employed, that instrument should be used (Fig. 7), placing its active point posterior to the tumor. This should be made the negative pole. The abdominal electrode should be placed in such a position that the largest diameter of the tumor is interposed between it and the vaginal electrode. A current of 50 to 100 milliamperes may be safely employed, if tolerated, for a period of five minutes. The treatments may be given as often as every second day, and in a few cases every day where it is well borne.

When a vaginal electrode can not be employed to advantage in these cases, a rectal electrode (Fig. 8) should be employed. This should be placed well up opposite the tumor. It should be employed as the negative pole. It should have an active surface of more than eight centimeters and the current should never exceed 200 milliamperes.

All we can expect to accomplish in this treatment is that beneficial action derived from passing a strong direct current through any tissue containing muscles, nerves, lymphatics and blood vessels, viz., a powerful

trophic stimulation to the part, and incidentally a powerful general tonic effect on the general system.

These cases get great relief. Neuralgias stop. Troublesome abdominal reflexes cease. Circulation is improved. Nutrition is stimulated. Sleeplessness disappears. Bowels are stimulated and relieved of troublesome distension symptoms. The tumors often seem to decrease in size. The degree to which each of these symptoms are relieved varies, of course, much in individual cases. The writer has seen a large number of cases completely and for an indefinite time, relieved of all these symptoms. In fact, some of the most gratifying cases of relief he has, are of this variety. Their cases are apparently so hopeless that often any relief is very gratifying.

THE RELATION OF GENERAL DISEASE TO THE FORMATION OF CATARACT.

Read before the Medical Society of the District of Columbia.

BY CLARENCE R. DUFOUR, PH.D., M.D.

WASHINGTON, D. C.

Physician in Charge of Eye Department Eastern Dispensary; Ophthalmologist and Otolist to Sibley Memorial Hospital, to Woman's Clinic; Assistant in Eye and Ear Department of Central Dispensary and Emergency Hospital, and Instructor in Ophthalmology and Otolaryngology, Georgetown Medical College.

The etiology of cataract may be classed under the following heads: Disease of the eye; diseases, which by some influence, exerted through the blood or the nervous system, interfere or impair the nutrition of the lens; and senile degeneration, certain pathologic conditions within the eyeball, especially of the choroid, are great factors in the production of cataract; yet may not the general or constitutional trouble manifest itself upon the choroid and these changes be secondary to the lowered health condition? The occurrence of cataract after middle life indicates the influence of senile change. It is generally conceded that senility or age exerts a powerful influence in the production of this condition of the lens. Cataract, in opinion of the writer, is not due to age, in the sense as we say that poisoning is due to the poison, or iodism to the iodine; it is senile in the same sense as atheroma of the arteries; it is a condition found associated with age, but all aged persons do not suffer from this condition. Clinical experience teaches us that the so-called senile cataract, after its beginning, is not steadily progressive, but may be marked by a steady increase, or periods of little or no change, and sometimes by a diminution of the opacity. Cases are on record where the patient having an incipient cataract, was told that it would be rapidly progressive; the physician was then informed that six years before the patient had been told the same thing by another ophthalmologist, and that between these times no diminution of sight had occurred, nor was the opacity greater. We frequently meet with cases the etiology of which is obscure, therefore, the causes which originate the opacity is of importance and of great interest. If the general physician were to become more familiar with the use of the ophthalmoscope, and were to make a careful examination of the media and fundus of the eyes, as one of the methods employed in the study of the symptomatology of general disease, much valuable information could be thus obtained in this direction and the ophthalmologist would then receive valuable data and not be compelled to gather it from scattered reports through the literature, the value of which may be questionable, and may only prove a coincidence; also, he will not have to

rely upon the statements of patients in ascertaining all the particulars as to the beginning of the opacity, and as to any history of general disease. Clinic patients are very uncertain and their statements are not always reliable. In the hospitals and clinics the physician and the ophthalmologist serve together in their respective capacities; this would seem to me to be an excellent opportunity to combine their skill in the study and treatment of general diseases from beginning to the end. The information thus gained would be invaluable, and add much to the literature of medical ophthalmology. I have for this reason brought this subject before the Society, hoping that it may be the means of gaining the aid and coöperation of the general physician in our researches along these lines.

I shall now present to you some of the general diseases which seem to have some relation to the formation of cataract.

Malaria.—Bagot reports two cases in which he says that two mulattoes after a severe malarial illness, had diminution of vision, and in a few months double soft cataract developed, which were operated upon, and visual acuity resulted, there being no disease of the fundus. Malaria will, we know, produce lesions of the vitreous and choroid, hemorrhages, which after absorption, leaves atrophic areas in the choroid; also, muscular paralysis, amblyopia and blindness, sometimes with no ophthalmoscopic findings. Then again it may be associated with congestion and edema of the papilla. Dubelir reports a case of blindness with exophthalmus and intermittent strabismus. Sulzer's cases had hyperemia of the disk, slight obscuration of the fundus, photophobia and seeing sparks; other complications which have been observed are iritis, suppurative choroiditis, chorio-retinitis, unilateral retro-bulbar neuritis with central color scotoma and hemianopsia.

Epidemic Influenza.—The epidemic of recent years seemed to affect the eyes to a considerable extent. In a variety of inflammatory affections Rampoldi made an analysis of 532 cases of eye affections which he saw in the spring of 1890; among that number were 48 who attributed their ocular trouble to this disease. These were corneal inflammations and abscesses, irido-cyclitis, conjunctival troubles, detachment of retina and muscular troubles, both internal and external. It would seem that such a disturbance as this disease caused in the eyes of those patients, that it might be more than probable that cataract would follow. In my own experience, this disease produces in those suffering from it the various ocular diseases such as I have named; also optic atrophy, both unilateral and double.

Typhoid and Typhus Fevers.—These two diseases cause considerable ocular disturbance, and we frequently find patients who state that their eyes began to give them trouble or to fail them after some intense febrile manifestation. Arens reports two cases, brother and sister, whose eyes became cataractous after an attack of typhus fever; an extraction gave good results. Trelat reports a cataract following typhoid fever, in a young girl. Fonton reports three cases of cataracta punctata, post-typhoidal cataract, which he thought was due to the disturbed circulation. Of these three cases, two of them, one a 28-year-old man, the other a 42-year-old woman, went on to maturity, and were extracted with good results. During convalescence, paresis of accommodation, with dilatation of pupil is frequent, not a true paralysis, but

as a part of the general debility; there is a tendency to phlyctenular affections of conjunctiva and cornea, sometimes passing into keratomalacia. Von Peterhausen reports double neuro-retinitis with macular hemorrhages. Leber and Deuschmann reported a case of double blindness with secondary optic atrophy and pigmentation of the entrance of the nerve. A case of a boy who had typhoid, examined by the writer, had an affection of the nerve and retina; his sight was much affected and his accommodation paralyzed. Four members of the same family had typhoid fever and the eyes of three were affected. The literature is full of the ocular affections due to these diseases.

Diabetes.—The frequent development of cataract in this disease is well known, and is due to disease of the vessels in the ciliary processes and to the disturbance of the nutrition of the lens. Knies states that it occurs mostly in young people, and that the cataracts are of a broad, striped variety, soft in character, which are associated at first with swelling of the lens. Frey reports double cataract in a girl of 9 years of age, one year after the beginning of the disease. The theories as to the causes of development of cataract in this disease are various. Knies cites the following, which have been advanced: 1. General marasmus, although feeble diabetics are not always attacked by cataract. 2. The removal of fluid from the lens through the medium of the sugar dissolved in the tissue juices; in two-thirds of the cases sugar has been detected in the lens and still more often in the aqueous humor and vitreous. According to this theory, the presence of a certain amount of sugar for a certain period, would produce cataract in all diabetics; this is not borne out by experience. Leber says that the clear as well as the opaque lens may contain sugar in diabetes, and Becker states that the cataract of one eye may contain sugar while the other does not. 3. The conversion of sugar in the aqueous humor into lactic acid, is stated as a cause. As the aqueous fluid is alkaline in diabetic cataract this seems to be a hypothesis; and then the opacity does not commence in the anterior cortical substance. As to the pathology of this disease, Deuschmann reports four cases of diabetic cataract, in which he found proliferation of the layer of pigment cells on the posterior surface of the iris. There were vesicular cells in the lens, and all changes from normal nuclei to entire nuclear disintegration; he therefore concludes that the opacity is due to a necrotic tendency of the epithelial structures; that if the epithelium is normal no pathologic process of diffusion can take place, even should the aqueous and vitreous contain sugar, but when the lenticular cells become necrosed, there are currents of abnormal diffusion set up and opacity is the result. Knies says that the cataract develops under the same conditions as spontaneous cataract, the result of processes in the choroid and particularly in the ciliary processes, which supply nourishment to the lens, the swelling of the lens and the proliferation process in its elements would tend to show that irritating substances are present, which stimulate the living cells to proliferation and then cause their destruction. Galezowski reports 544 diabetic eye cases, in which 31 per cent. of them had cataract and only 19 per cent. had retinal changes. Maulthuer believes that the abstraction of water from the tissues, with the presence of glucose, produces cataract, in diabetics.

Syphilis.—By the disturbance of the nutritive pro-

cess in the eyes secondary cataract sometimes follows this disease. Bos describes several cases of true syphilitic cataract, seen in Bandall's clinic, also speaks of cases seen by Rominee and Heller. He divides them into two classes, capsular cataracts in which iritis is present and lenticular or true cataracts, which are directly due to this disease, and are not frequent. They appear in the secondary period of the disease, and are soft in character, with no inflammatory process of the ocular coats.

Rachitis.—This disease is often the cause of laminated cataract, due to an intense disorder of nutrition in the lens. If it develops at a very early period or is intra-uterine, a central cataract forms. When this adheres to the capsule of the lens at the anterior and posterior poles, it contracts into a slender opacity and forms the so-called spindle-shaped cataract. Laminated cataract appears to be cortical in character. The opacity may at a later period move away from the capsule on account of new normal cortical substance being formed. This form of cataract is symmetrical in both eyes, but sometimes is unilateral, and sometimes congenital. The larger number of cases develop in the early life of rachitics. Knies says that it is not the rachitis, but the violent and long continued convulsions that cause the cataract, and that these spasms must occur at a period when the growth of the lens is still active, *i. e.*, before six years of age, to cause the lenticular opacity. Arlt does not believe the real cause to be the general convulsions and the consequent concussion of the body, but the nutritive disturbance of the lens due to the violent spasm of the ciliary muscle associated with spasm of the muscular coat of the vessels. The opacity usually develops from a few days to several weeks after the convulsions; in rare cases it spontaneously disappears. In cases of congenital cataract, or if developed at a very early period and is very dense, psychic blindness may develop after an extraction, due to the imperfect development of the tracts between the brain and the eye. Horner says that an analogous condition is observed under similar circumstances, in another organ, which is genetically coördinate with the lens, *viz.*, the enamel of the permanent teeth, particularly the upper incisors, exhibit horizontal grooves and ridges, *i. e.*, places where the enamel is alternately present and absent, the change is only distinctly seen during the first years after the appearance of the teeth.

Diseases of the Skin.—Mooren states that he has often seen cataract develop during chronic cutaneous eruption. Rothmund saw it develop in early childhood among the children of three families, these having a peculiar skin affection. He states the disease to be reticular, fatty degeneration of the stratum of Malpighi and of the papillae, with secondary atrophy of the latter and rarefaction of the epidermis; this disease began from the third to the sixth month of life, the cataract between the ages of 3 and 6 years. Of fourteen children of three families living in three adjacent villages, seven suffered from skin disease, and five of these had cataract. Nieden observed the formation of cataract in a girl 22 years of age who suffered from telangiectatic dilatation of the capillaries of the entire integument of the face; he also emphasizes the relation between skin diseases and cataract.

Whooping Cough.—Wright reports a case of a boy, 18 months of age, who had this disease and afterward developed cataract. Knapp saw bilateral blindness, from retinal ischemia. Loomis says blindness in per-

tussis occurs almost exclusively in those who die later of pneumonia. Jacobi reports cases of sudden maximum mydriasis and immobility of the pupil, together with double optic neuritis. Alexander and Landesberg, both report hemorrhage into the optic nerve, terminating in optic atrophy. The latter person, also saw the obliteration of the two upper branches of the retinal arteries and subluxation downward of the right lens.

Nervous Diseases.—Logetsehnkow reports fifteen cases between 16 and 37 years of age, who suffered from convulsions and who afterward developed cataract; all had had good vision except one, before the seizure. He thinks that the cataract is in relationship not alone with the convulsive seizures, but with the nervous lesion, which is the cause of the convulsions. Sewill reports a case of spasm of the right orbicularis, and the subsequent development of cataract; the spasm was caused by a carious tooth which upon being removed, ceased. He explains this phenomenon as due to trophic changes in connection with the trigeminal ganglion. Bock reports five cases between 34 and 39 years of age, who had meningitis and who subsequently developed cataract, underwent an operation and good vision resulted. No convulsions were present in these cases.

Pellagra.—The characteristic ocular sign of this peculiar disease is night blindness, although ophthalmoscopic findings are not uncommon. Stroppa saw two cases of optic atrophy; Neusser, diplopia and amblyopia; Rampoldi, retinitis pigmentosa, optic atrophy, disappearance of the choroidal pigment, ulcers and necroses of cornea, opacities of lens and vitreous.

Nephritis.—Deuschmann calls attention to the possibility of a connection between this disease and cataract; he reports twenty-one cases of lenticular opacity, finding albumin in 7 per cent. of these, and in six established the presence of nephritis. In 1881 he found among fifty-three cataract patients 9.5 per cent. of these had Bright's disease. Still later he examined 230 patients with uncomplicated cataract, 5 per cent. of whom were nephritic, and 11.1 affected with Bright's disease. Landesberg examined 376 patients with uncomplicated opacity of lens; he found sugar in the urine of 3, sugar and albumin in 2, and albumin in 44, and 327 with normal analyses. Rothzeigle found albumin in about half of his cases, and describes fifteen cases of chronic nephritis with cataract. Evezky, in investigating Deuschmann's theory, adopted three methods; he examined 200 cataract cases for albumin, 35 being under and 165 over 50 years of age. In thirty-eight he found albumin, 19 per cent.; in sixteen the albumin was constant; in 9 per cent. there were albumin and tube casts, these were under 50 years of age. He examined ninety-seven cases of chronic nephritis; seventy under 50 and twenty-seven older. The eye affections were albuminuria, retinitis, cataract, posterior synechia, opacities in vitreous, detached retina and synchysis scintillans. Incipient cataract was found in eight cases 8.2 per cent. Of 584 old persons examined 15.2 per cent. had incipient cataract, of these 2.09 per cent. were in the 6th decade, 45.75 in the 7th, 52.6 in the 8th and 66.6 in the 9th. In fifty-nine cases, 10.5 per cent. of albumin was found in the urine, and in 1.6 per cent. tube casts; 10.5 per cent. of the cataract cases showed albumin; of the non-cataractous, 9.8 per cent. True nephritis was found in the cataractous

cases in 0.8 per cent. and 2.1 per cent. in the non-cataractous cases. He concludes that albumin does not mean nephritis, that nephritis and cataract may combine, that there is no cataract in young nephritics, and in old ones, no more than is usually found in those without the sign of Bright's disease. The exact relationship between the development of cataract and nephritic disease, may not be positively shown. Yet there is evidence sufficient to lead one to believe that there is some such relation and in all cases of incipient cataract the urine should be carefully examined. Webster Fox very wisely says, "Whether albuminuria causes cataract may be a matter of doubt, but one is struck with the frequent coincidence of albuminuria in cataract patients. Michel says that cataract and albuminuria are the results of alterations produced simultaneously in the eyes and in the kidneys, from the same general cause, arterio-sclerosis.

Diseases of Heart and Blood Vessels.—Michel says that opacity of the lens is a symptom of a local or general disturbance and that cataract is caused by sclerotic changes in the walls of the carotid, in fifty-three cases he examined, fourteen of them had monocular cataract with atheroma of the carotid on same side; in fourteen there was double cataract, more developed in one eye corresponding to the side of the greater atheroma; in nine cases there were double cataract, which developed simultaneously with a double carotid atheroma; in eight cases of cataract there was sclerotic change in the carotid and on this same side there was thyroid enlargement. Karwat gives cases which confirm Michel's report, stating that there is a relationship between atheroma of the carotid and the formation of cataract.

In conclusion I would enter a plea to the general physician to aid us as much as possible in our research in this direction, that the etiology of many of our cataract cases which are now obscure, may be cleared up and better understood. I would suggest that the eyes be tested for their visual acuteness, at regular intervals; the interior of the eye should also be examined to determine if cataract be present, and as to how far the sight is affected by it, and if other causes are present, how far the impairment of vision is due to them. We must exercise careful supervision of the patient for any symptoms which point to impairment of the general health, and especially for any which show trouble of circulation and digestion. The interest of the patient demands this supervision, for by it we will become more familiar with the nature, prevention and removal of the general conditions which may be the cause of the formation of cataract. As before stated, in all cases of incipient cataract, careful analysis of the urine should be made at different intervals. Though we may not have proven a direct connection between general disease and the formation of cataract, yet it can not be denied the existence of a predisposing cause in all diseases where there is impairment of nutrition and lessened vitality.

1016 I Street, N.W.

Cold Baths in Delirium Tremens. The *Presse Méd.*, 1896, No. 4, announces that cold baths, eighteen degrees C., have been found very effective in quieting even the most violent attacks of delirium tremens. The patient is placed in the water up to his shoulders and it is poured over his head. The bath is repeated two or three times in the same day. The effect was surprising in two cases described, where all other treatment had been without results. A few glasses of warm wine were given afterward, followed by quiet sleep for two hours.

REPORT ON AMPUTATIONS AT THE JUNCTURE OF THE TARSAL AND METATARSAL ARTICULATION.

Delivered at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY W. J. GALBRAITH, M.D.
CHIEF SURGEON UNION PACIFIC RAILWAY.
OMAHA, NEB.

I regret exceedingly that neither of the cases I desired to exhibit at this meeting are here. Owing to the fact that I am obliged to return to Omaha to-night, they will not be here in time for me to exhibit them. I secured transportation and gave them the necessary means to pay their expenses, but some unavoidable accident has delayed them.

I believe the treatment that was applied to this case and one other since that I have operated is entirely unique. It is very difficult for me to describe to you accurately the treatment this case received. It was impossible for me to make a Lisfranc operation on account of the destruction of the tissues a little proximal to the tarsal and metatarsal articulation. In the customary treatment of these cases a Symes or Pirogoff operation would undoubtedly have been made. I explained to the patient, who was a railroad man, that I would like to experiment to a certain extent upon this foot, that the experiment would not be injurious to him in any manner, only that it might retard for two or three weeks the repair in his case. He was very willing that I should try anything that would save any part of his foot. The tissues, as in many railroad injuries, were completely pulpified, lacerated and contused. The point of complete separation, as I have described, was at the tarsal and metatarsal articulation. You will all readily understand the amount of retraction there is in the skin after an injury of this kind. I proposed to the man that I make a complete section, that is, taking my knife and trimming all the tissues transversely at the seat of the injury across the foot, going back just a little above the metatarsal articulation. The head of the metatarsal bone was removed by the saw or forceps, I do not remember which. It was my object to cut it as high up into the tissue as possible. Thorough antiseptic precaution was preserved throughout the entire operation. A moist dressing was applied for four or five days, and about this time it was changed and a stimulating dressing, composed of equal parts of sterilized balsam of Peru and sweet oil was applied directly over the wound, in order to stimulate and secure as early as possible a granulating process. After securing, at the end of about eighteen or nineteen days, a good bed, so to speak, of healthy granulations, I skin-grafted after the method of Thiersch with excellent results.

Now, I believe, in fact I am positive, that I saved at the least several inches of that man's foot, enabling him to perform the duties of a switchman nearly as well as he did before he met with the accident. It would be utterly impossible with a Symes or Pirogoff operation for a man to perform these duties. You know as well as I that many surgeons to-day, especially in the East, are recommending in preference to the Symes and Pirogoff operation, an amputation of the middle or lower third of the leg. Now, what is the result? In this case we have succeeded in getting a foot that a man can perform his duties with. He goes about nearly as well as he ever did. And the result to the railroad is what? This man's case was settled for \$200. If a Pirogoff operation, or an amputation at

the middle third, which is often preferred, had been performed, the amount paid would have been perhaps \$2,500.

Now there are a great many points to be observed in the treatment that I have applied to this case, and the other one which has been equally as successful. You all readily understand how slow granulation takes place over a cartilaginous substance. It requires weeks and even months, and by the time you have secured a granulating surface over the articulating surface of the bone, the surrounding granulations are exuberant, broken down, or indolent, and your skin-grafting is a failure. The object is to secure as good a bed of granulations and at as early a date as possible, and I believe you will accomplish the same results that I have in this case.

DISCUSSION.

DR. H. REINEKING, of Sheboygan, Wis.—I was very much interested in the report of Dr. Galbraith, on account of two patients which I have recently had occasion to see. I will first speak of a case Dr. Etley, of New Richmond, presented at the last meeting of the Wisconsin State Medical Association, a case where all the soft tissues of the sole of the foot had been torn off in a railroad accident. As he described it, the bone was perfectly bare. He resorted, not to the skin-grafting of the tissues, but to skin transplantation after the plan of Krause. He showed the patient at that meeting and the result was indeed beautiful.

In a case that I treated recently, an injury resulting from a boiler explosion, the injury consisted in a compound fracture of the olecranon process with a severe scalding of the entire posterior surface of the arm. The burn was of the third degree. The body was also extensively scalded, but in that location just where the elasticity was most wanted after the bones united, there was a very deep burn. Here I resorted to the same mode of skin transplantation, transplanting the whole thickness of the skin down to the adipose layer. The area covered had a length of fourteen inches, and at the widest portion, four to six inches in width. Four elliptical portions were taken from the patient's thigh and cut into small sections and transplanted to his arm. Every particle of this skin, I am glad to say, adhered and in about two weeks' time success was assured.

This process of skin transplantation I believe superior to Thiersch grafting. It is not necessary to have a granulating surface, in fact the granulations were all carefully scraped away in this case. According to Krause, skin grafting in this way can be made on bare bone, cartilage, fibrous tissue, or almost any tissue in fact as long as the surface on which we transplant is absolutely aseptic. Asepsis is the one great requirement for success in these cases. It is not necessary to first have a healthy granulating surface: it can be done in recent injuries; it can be done in various shapes after scraping away the entire skin and, as I say, the healthy granulated surface is not essential.

DR. MAYNARD—In connection with this case, and in the same line of thought, about 1876, or 1877, I learned how to borrow skin for grafting. I did not know anything about grafting then, but I found in an arm injury, for instance, if you cut too close and get a slough just take a piece of strap and put a pine shingle on and make a little steady pulling and it is wonderful how much skin you can borrow with which to cover your granulation. I seldom graft if I can borrow. Make a steady pressure and it is wonderful how the skin will give and will grow. It will apparently make new skin. It probably would not have answered in Dr. Galbraith's case, but had it been my case, I should have put on a little slow tension with a rubber band or a rubber strip over the front and base of the foot, and would have tried to get it that way. If you will try this you will be surprised with the results you will get.

DR. BEVAN—I would like to make one remark in the same line of work on the importance of conservative work in finger and toes and hands in railroad surgery. For a number of years I have made it a point practically never to make a peremptory amputation of any part of the hand after a railroad crisis, except where the part was entirely crushed from the hand, and have not cut away any portion of the tissue, except that which was entirely destroyed. Next in this connection, is the value of a wet boracic acid or borax dressing. I have always employed wet dressings and kept them continually wet in these cases until I could determine the amount of tissue that had been destroyed. Borax or boracic acid in the strength of about one to one hundred is not antiseptic, but it does inhibit the growth of germs and I have repeatedly taken fingers, which were turning black and becoming gangrenous, and wrapped them in wet boracic acid and watched them for from ten days to two weeks. They have simply mummified without any infection. One point I would like to mention in regard to Thiersch's graft and skin transplantation: Skin transplantation is the ideal operation if it can be made successfully. It can not be made successfully in enough cases to warrant us in employing it. Skin transplantation certainly in large masses, as far as my own experience is concerned, and it is fairly wide in this matter, has not been successful in more than about half of my cases: in about half the cases there has been failure of fusion, and this same experience has been met with in the hands of my colleagues at the Presbyterian Hospital. There is this objection to transplantation, that if you remove a large area of skin and it fails to unite you have done an injury to the patient and he feels that he has been to a certain extent mutilated by the removal of the entire thickness of his skin. In the Thiersch graft, where you split the skin, you can remove fifty square inches from the patient's thigh, and in a week he is practically as sound and well as ever. So I do not believe that we could make this statement that skin transplantation will take the place of the Thiersch graft because of the facts that I mention.

DR. REED—I only have a word to say. I regret I did not hear all the doctor's report. I wish to speak only in reference to the manner of transplantation of skin. The objection spoken of by Dr. Bevan is one which we all know patients are liable to make: that is, in being skinned themselves in some part to cover some other part. It is sometimes necessary to borrow integument from some of their neighbors, and it seems to me that the use of the frog skin in cases of this kind obviates to a large extent this objection, and would give, so far as my experience is concerned, practically the same results. I know of several instances in which the frog skin has been used. One I recall in a patient who had a very large ulcer. This, however, was a varicose ulcer, but it answers the same purpose to demonstrate the use of the transplantation of skin in a case in which I had little confidence. In this case we used a live frog and skinned off the integument of the abdomen and placed it over the ulcer and the results were quite gratifying, rapid, and not only rapid but they were perfect, just as much so as in another case that was operated about the same time in which we used the Thiersch graft. I simply make this suggestion in the hope that it may help out in cases of this kind where we can not get integument safely from the patient or his friends.

DR. KIBLER—One word on the subject of skin graft. I have a plan of my own on that point which I have not said much about. I do not use skin at all, but I use the epithelial tissue, the rough, horny epithelium that you get from a working man's hand. I recently had a case of skin injury received by an elderly gentleman sixty odd years old, from scalding, some four hundred square inches in area, and to-day his skin is perfect and his muscles are seemingly as limber as ever, without much contraction. Simply take the rough, horny epithelial tissues which you will find upon the palm of a working man, or upon

the sole of the foot of any man, and you have a good substance for grafting as you can possibly ask for. Try it.

A MEMBER—I will ask the doctor to give the technique.

DR. KIBLER—First the ulcerating surface should be washed thoroughly with a boracic acid solution; then take a little piece of thin tissue from this horny surface that I speak of, not thicker than tissue paper and not larger than a split bean perhaps. This is placed directly upon this raw surface, covering it with a protective, over which is put adhesive plaster. When the plaster is removed it does not disturb the grafting whatever, whereas, if you should put the plaster directly on the grafts themselves, they would likely be withdrawn whenever the plaster was removed. This little mackintosh covering or oiled silk, if you wish, affords a substance to give you the finest results.

THE USE OF COCAIN IN MINOR AMPUTATIONS.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons held at Chicago, Ill., Sept. 25-27, 1895.

BY C. M. DANIELS, M.D.

CHIEF SURGEON, W. N. Y. & P. RY., BUFFALO, N. Y.

Appreciating that at this, the second meeting of the Academy of Railway Surgeons, many papers of highly scientific and scholarly character would be read, I have ventured to tender one that may be as a rest "between the acts," but of a strictly practical character, and based entirely upon personal experience. I offer this brief paper as a fragmentary contribution to the literature upon cocaine as a local anesthetic.

The question and study of anesthetics is always germane to the subject of surgery, and as railway surgeons we are close observers of the action of chloroform, ether and the other essentials used by way of inhalation for the purpose of producing neurotic narcosis for the relief of pain in our operative work.

Safety is, or always should be, our first consideration. The loss of sensibility, known as anesthesia, may be general or local, being dependent upon the agent and method used to induce the same; and the scope of this paper deals entirely with that of a local character. If experience is of value, I believe it will lead many of our surgeons to entirely abandon the use of chloroform, ether, etc., in minor amputations.

I feel that there are many members of the Academy, as well as others, who may have greater experience than myself, but from the meagre amount of literature upon the subject, they certainly have not given us the benefit of their experience. The text books mention the subject of cocaine in minor surgical operations, but do not clearly define the technique in a way sufficiently practical to cause the surgeon to give the subject but a passing glance.

All do not have the benefit of hospitals, with trained assistants and conveniences and I hope this paper may especially benefit those surgeons who do much of their work out along the line where minor amputations are of frequent occurrence and the surgeon is without competent aid.

For the past eighteen months I have used muriate of cocaine in very weak solution, *exclusively* in minor amputations and feel like shouting "eureka" at the conclusion of every operation, except, of course, that I am not entitled to use the personal pronoun.

For the benefit of those interested, I will briefly detail method of procedure, taking for instance a crushed finger.

If the stump is long enough, after putting it through the preparatory toilet of soap, water, ether, etc., I tie

a narrow wet bandage which is always at hand and acts as a firm cord, tightly around it close to the knuckle joint. Then with a clean hypodermic syringe and needle I inject about ten or fifteen minims of a 2 per cent. solution of cocain, freshly prepared with sterilized water, immediately behind the proposed incisions, introducing the needle as follows: First upon the dorsal aspect letting it enter about one-half inch to one side and expelling three or four drops of the solution. I then partially withdraw the needle and gently turn to the opposite side expelling the same amount; then partially withdraw it again up to the median line and deposit an equal amount at the point of entrance immediately beneath the skin.

You will note that fully one-half of the finger stump has received the solution and with but one puncture of the skin. Turn the hand over and repeat this from the palmar surface and in six minutes go ahead and amputate the finger and your patient will be in blissful ignorance of the pain. After completion of the operation and before closing the flaps squeeze, or I might say "milk" out, the cocain solution from the tissues, which can be quickly and readily done. Remove the constricting bandage, see that all bleeding is controlled, close the flaps in the usual way, and you will have performed a painless operation and one entirely free from the danger of poisoning, for if properly done, in my judgment, there will not be to exceed $\frac{1}{3}$ of a grain of cocain absorbed, which amount we all know is absolutely harmless.

One-fourth of a grain for each finger I deem ample, and as I commenced with a 4 per cent. solution in the early part of my experience and am now using but a 2 per cent. I think the strength may be still further reduced, but recommend that a larger quantity of the solution be injected, practically "flushing" the tissues at and immediately above the point of operation.

For operations at the knuckle or immediately behind, I use the same method with the constriction, but find it necessary to work a little more rapidly on account of absorption of a portion of the solution as the operation proceeds.

While I have especially referred to the hand in a descriptive or explanatory way, operative work under cocain may, in my judgement, be liberally extended.

DISCUSSION.

DR. ELISHA GRISWOLD—I would like to ask Dr. Daniels whether in his opinion, when injecting cocain as described in this paper, the anesthesia extends from the point of injection some considerable distance from the end of the finger: that is to say, suppose you make a flap half an inch from the end of the finger, at which point you inject the cocain, is that point anesthetized as a general rule? Furthermore, I will say, I have used cocain a good deal in small operations, not much in amputation of the fingers, but to a considerable extent in the excision of small tumors. In some cases I have used it as a matter of election because the patients desired it. One patient, an old lady, 81 years of age, had an epithelioma involving the bridge of the nose and extending slightly into the cheek. She had insufficiency of the aortic valves, so that she was not a good subject for anesthesia by the ordinary method. But she was quite willing that cocain should be tried, and in her case about three years ago I injected it at points about one-quarter of an inch apart all around the tumors as near as I could. I used a 4 or 5 per cent. solution. In removing the tumor I cut a branch of the nasal artery, but by compression and torsion I was enabled to stop the hemorrhage, although it was quite a time before it was completely arrested. An effort was made to cover the open surface of the wound as well as possible with skin, but

I could not do so because there was not enough skin with which to do it. When I went to insert the sutures some little distance beyond the point at which the cocain was injected, the patient felt the needle somewhat but not severely, and I find this to be the case with the removal of other tumors. In the case of a fatty tumor on the back I found, after removing the tumor and getting ready to insert my sutures, that the patient felt the needle, although she had not felt the knife in the removal of the growth. And so I would like to know if Dr. Daniels in his experience in amputating fingers with cocain, can tell us whether the anesthesia extends from the point of the finger so as to give plenty of room to operate, and so that the patient will not feel pain in making the flap.

DR. HENRY W. COE—Any one who has used cocain to any great extent in surgical practice, especially in very strong solutions, must have seen some very sick patients, for he does not know beforehand exactly how his patients are going to react. I consider cocain a dangerous analgesic, as ordinarily used. I think it is dangerous where a patient has serious heart trouble, and that in such case chloroform would be preferable. I know, of course, that the matter of personal equation comes in here. I know I would much prefer to use chloroform. I remember a case in which I began to operate for hemorrhoids, in which some authors would have said that cocain should always be used, and I am sure will never use it again. My patient came so near dying that I was frightened half to death myself. The method the doctor advocates, however, consists largely in complete saturation of the tissues. He uses a 2 per cent. solution. I have used even a weaker solution than that and a considerable amount of it with which to saturate the tissues. If we use a weak solution we need to operate rapidly because of the fact that the fluid will pass out through the wound, which is a point the doctor did not bring out in his paper.

DR. WEBB J. KELLY—Dr. Coe speaks in the discussion of the use of cocain during an operation for hemorrhoids. I do not know what the experience of other members of the Academy has been, but it has been mine when any operation has to be performed for hemorrhoids or other conditions in this locality, that chloroform or any anesthetic is likely to act badly: and I think probably that this fact is one reason why he has had so much trouble with cocain in operating on the rectum. I have had experience with cocain personally, inasmuch as Dr. Straight, last winter, sawed out a large piece of bone from my nose, using a 20 per cent. solution. They walked me around for three or four hours in order to keep me from dying, consequently I know what it is. Personally, I do not like to use it.

DR. L. E. LEMEN—I do not feel that I can go home satisfied without contributing a little to this paper in the way of discussion. For some time I have performed all amputations of the fingers very much in the manner that the essayist has described, more particularly in those cases that come to the physician's office where it is quite inconvenient to use a general anesthetic. If a general anesthetic were used in one's private office, he would have to wait until the patient recovered from the influence of the anesthetic, and send for a janitor to clean up the mess afterward. I have used a 4 per cent. cocain solution for several years in amputating fingers, the amount being governed by the number of drops I would put in. I wait for fifteen minutes instead of six, after using the injection before I begin my operation, and have my attendants watching to see whether the patient flinches or not. The anesthesia lasts from five to eight minutes, which gives the surgeon the ordinary length of time to perform the operation and insert sutures. Instead of using gauze I use rubber bands. I take a rubber band, drop it in the solution, if I use antiseptics (I keep sterilized water in my office for this purpose), keep it in the solution for a little while prior to giving the injection of cocain, and then I put the band around the finger so as to localize the anesthesia. This

controls hemorrhage completely. I have had no trouble from the use of cocain in this way, and I have amputated as many as two and three fingers at a time. I would amputate one finger, then I would inject the second finger, operate, sew up the flaps, disposing of one finger after another. There is only one objection to cocain, and that is its tendency to produce more or less edema in the neighborhood of the tissues that have been injected with the solution. I believe any solution, even pure or salt water would produce the same effect. While it may not come under the head of railroad surgery altogether, I will say that in children it is not well to use it because they struggle against your efforts. In adults I use it for the purpose of circumcision, and use a rubber band to control the hemorrhage as well as to localize the anesthesia. We will find subjects occasionally on whom, owing to their nervous temperament, no matter how slight the operation may be, cocain has a depressing effect. I have seen people faint from ordinary vaccination, even before I put the lancet to their arms. It is the mental effect, the very thought of being operated upon. In these subjects, where the nervous temperament exists to any great extent, I believe it would be better to use an ordinary anesthetic on account of the depression which may continue for some time: in other words, there is more shock than we ought to have from a simple surgical operation. In people of a nervous temperament I would advise a general anesthetic where it is not contraindicated.

DR. F. J. HODGES—I believe if the gentlemen using cocain will experiment with it a little, they will use much weaker solutions than have been mentioned here and still get good results. A great many men use a solution which would probably be not more than one-half of 1 per cent. of cocain, containing common salt, and a very small proportion of carbolic acid and a moderate amount of morphin. Their philosophy of this procedure is this, that after all it is the pressure of the fluid within the tissues which is the active factor in producing anesthesia. There are a number of physicians in my part of the country who use regularly this solution in the strength I have indicated and do perfectly painless minor operations.

DR. JOHN E. OWENS—The last speaker mentioned the fact that he thought perhaps even weaker solutions would be useful. Some gentleman wrote an able article upon this matter in one of our Chicago medical journals, in which he recommends the use of weak solutions, and said that almost infinitesimal doses were followed by gratifying results. I suppose it would be in order to mention another local anesthetic, although the paper is on cocain. I would like to call the attention of the gentlemen present to ethyl chlorid, which surpasses anything I have used up to date. It is a fluid contained in a glass reservoir and costs a dollar. It is kept from spilling by means of a cap at the conical end. It is an excellent local anesthetic for the removal of small growths. I have removed a small growth of the breast with it and also amputated a little finger. I believe it is a good substitute for cocain.

DR. DANIELS (closing the discussion) Replying to the inquiry of Dr. Griswold, I will state that I have always found that I could operate from the knuckle to the distal point of the finger, in injecting between the knuckle and middle joint, without any pain whatever. But it is my practice always to inject the cocain immediately behind the point where I am to operate, and not to inject near the knuckle, but as far down as the operation is to be performed, consequently I am sure of anesthetizing the point desired.

As far as mentioning the use of cocain for the purpose of removing larger growths is concerned, I will say that my paper dealt entirely with its use in minor amputations. I have also used it in removing small tumors as described by other gentlemen.

Dr. Hodges' remark in regard to weak solutions is only an echo of the remark I made in closing, that a much weaker solu-

tion can be used with equal benefit. I commenced with a 4 per cent. solution, and have reduced it in some cases to 2 per cent. and the results were the same; only in using the latter I used a little bit more. It may have the same effect he refers to, so far as the tissues are concerned, on account of the presence of what may be termed a foreign body. I also think constriction of the finger under pressure bandage may have something of an anesthetizing effect. I have amputated on several occasions four fingers. I would inject one with cocain, amputate it, then inject another, amputate it, etc. I have not used it in cases of circumcision, but for the purposes mentioned in the paper I have used it for the last two or three years exclusively.

GANGRENE OF THE EAR.

BY S. S. BISHOP, M.D.

Attending Surgeon to the Illinois Charitable Eye and Ear Infirmary; Professor of Otology in the Post-Graduate Medical School and Hospital; Professor of Diseases of the Nose, Throat and Ear in the Illinois Medical College, etc.

CHICAGO.

Gangrene affecting the ear is a very rare disease. It is mentioned in but three out of seven books on the ear, in my library. I have never seen a case in private practice, nor in my service at the various hos-

FIG. 1.—Showing extent of gangrene of auricle (dark area).

pitals and dispensaries, until the following one appeared at my clinic at the Illinois Charitable Eye and Ear Infirmary:

Jan. 8, 1896, George T., 2 years old, was admitted as a house case. Five months ago he was placed by his mother in an orphan asylum. Two months ago suppuration of the right middle ear developed and continued to the present time, and five days since, the concha turned black and emitted a foul stench. The characteristics of the pulpy form of hospital gangrene were present, and Dr. Lieberthal, the dermatologist, who saw the case with me, confirmed the diagnosis of gangrene.

The necrotic process involved both anterior and posterior surfaces of the concha to the extent of the dark area shown in Fig. 1, and had begun to invade the integument covering the mastoid process.

The child was placed in the care of one of my assistants with instructions to give a nutritious and stimulating diet, for it was badly nourished, and to

remove the necrotic tissue and apply warmth to the parts so as to increase the blood supply.

January 8, my assistant removed with scissors the diseased concha, leaving an aperture the size of the dark spot in Fig. 1, and also the discolored skin of the mastoid, adjacent to the auricle. The soft tissues of the canal were excised and the mastoid operation was performed, Fig. 2, for the necrotic process had extended to the osseous structures. The wound was dressed with iodoform powder, iodoform gauze, absorbent cotton and an eight bandage. The child rallied well. At 8 P.M. the temperature was 101° F. On the 9th, A.M., temperature was 100.3° F., and the odor had disappeared. A few points of dark grayish discoloration appeared and were removed.

Progress was excellent until measles developed on January 25, followed by pneumonia. Then all granulation formation ceased. The wound assumed a dried, anemic and withered appearance, and the little patient died on January 31. Its mother had just buried one of her other children, all of whom had measles. Had

Fig. 2.—Auricle reflected forward, showing mastoid operation completed.

the child lived I should have resorted to a plastic operation to cover the denuded bone.

Post-mortem examination, as reported by my assistant, showed miliary tuberculosis of the lungs and pneumonia of the right lung, hyperemia of the cerebral meninges, hydrocephalus; heart normal.

Among more than twenty thousand cases of diseases of the ear treated at the Infirmary we had no record of a gangrene of the auricle, although Politzer, Schwartz, Kurekenberg, Moos, Nottingham, Riegler, Eitelberg, Boyer, Obre and Bourdillot have met with it. In the present instance, the cause of the gangrene was a chronic suppurative inflammation of the middle ear and external canal, combined with malnutrition. Whether the auricle had been subjected to pressure or severe cold could not be ascertained, since the mother had not seen her child for five months, and no definite information was obtainable at the orphan asylum.

Gangrene sometimes arises without any assignable cause; but any condition that vitiates the blood, lowers vitality and the powers of resistance, in the pres-

ence of a local exciting cause such as cold, pressure, acrid discharges, burns, etc., predisposes to this necrotic process.

Bourdillot and Nottingham reported cases following measles, while in my case this order was reversed.

I am indebted to Dr. Carl Theodor Gramm for the photographs for my engravings.

103 State Street.

THE CAUSE OF DEATH OF PROMINENT PERSONS.

BY RALPH S. MICHEL, M.D.

SPRINGBORO, OHIO.

A curious interest attaches to the demise of a friend. When "the rider on the pale horse" stops at the house of a friend, we seldom fail to inquire the cause of death. Death is to us so deep a mystery. It changes a being full of energy and life and hope, into an inanimate object, with a rapidity that is appalling. We stand aghast in its presence. The friend, whose welcome smile we meet to-day, is dead to-morrow. We eagerly inquire the cause. So it seemed to me that it would be of interest to make a collection of facts in regard to the death of celebrated persons: those whom we have learned to know and love from their written pages; and those whose deeds have moved men's hearts, in the times in which they lived. It is impossible to ascertain the cause of death in many instances. Diagnosis has acquired a degree of accuracy but very recently. In many cases the cause of death is given as "a fever," which is indefinite. And often the cause is unknown or not stated. The following, however, is believed to be reasonably accurate.

Early in the spring of 1616 Shakespeare and his boon companions, Ben Jonson and Michael Drayton, spent the evening at a tavern at New Place. All became too much intoxicated to reach home, and laid out all night on the ground. The consequence to Shakespeare was a "fever" of which he died in a few days. It was undoubtedly pneumonia.

Lord Bacon died at 65, a martyr to science. While riding one winter day, it occurred to him that snow would preserve flesh, as well as salt. Accordingly he alighted, bought a hen, and stuffed it with snow—at which operation he became much chilled. He was too sick to return home, but stopped at the house of a friend. Their kind hands put him in a cold damp bed—the "best room" perhaps—and he died in a few days. Probably pneumonia.

Burton, author of the "The Anatomy of Melancholy," believed in astrology. He calculated by the stars the time of his death. He died at the time assigned, but was suspected of taking something to hasten it in order to make it conform to his calculation.

"O Rare" Ben Jonson had several attacks of apoplexy. As a consequence his mental faculties became much impaired. His last days were dark and gloomy.

Motherwell died at 38 of apoplexy.

Ben Franklin had gout; also cystic calculus and the attendant inflammation of the bladder confined him to bed for a year. He was then 84. The immediate cause of death however was abscess of the lung.

Washington died at 67 of acute laryngitis, complicated with edema of the glottis. On Dec. 12, 1799, he rode over his estate on horseback. It was a day of rain and sleet, and he became thoroughly chilled. He contracted a severe cold, and at the end of two days

was very sick. Before sending for the doctor he had his overseer to bleed him. When the doctor came he bled him again. Still there being no improvement a consulting physician was called. They bled him again. Being no better, they gave him tartar emetic and calomel. They also applied fly blisters to his throat. The medical treatment has been the subject of much criticism.

Edward Gibbon, the historian, had the largest hydrocele on record—as large as a bucket. Repeated operations for relief exhausted him, and he died of a “fever” brought on thereby at 57.

Napoleon died of cancer of the stomach.

Thomas Gray, author of “An Elegy Written in a Country Churchyard” died at 55. He was subject to hereditary gout. One day at dinner, he was taken suddenly and violently sick, with pain in the stomach, and died on the sixth day.

William Collins, the poet, died at 36 of paresis or insanity, brought on by dissolute and intemperate habits.

Akenside died suddenly at 49 of diphtheria.

Burns died at 37. Of convivial habits, he perished from drink and exposure. One day in January, 1796, he dined at a tavern in Dumfries. He was barely convalescent from a spell of sickness, and was in no condition to stand exposure. The night was cold, and Burns, wandering homeward in an intoxicated condition, sat down upon a doorstep, and fell asleep. Rheumatism supervened, and although he lived until the next July, he never recovered. During the last few days of life, he was in a state of low muttering delirium.

Byron was born with “club foot.” His mother, who was a misanthrope, always spoke of him as a “lame brat.” This defect was finally remedied to the extent of enabling him to wear a common boot. He early showed signs of obesity. This was to him a matter of much chagrin, and he combatted the tendency by very low diet, and medicine. He died in Greece at the age of 36 of heart complication, coming up during an attack of acute inflammatory rheumatism. Death was sudden.

Oliver Goldsmith died at 45. He was a man of somewhat irregular habits, and was attacked with dysuria, probably amounting to strangury. His death was attributed to “James’ powders” which he would take contrary to the advice of his physician. But as he died of “strong convulsions,” it is likely death was caused by uremia. “James’ powders” was a secret remedy. It can not now be prepared as it was by Dr. James, owing to ambiguity in the specifications placed on file in the Court of Chancery. But it is composed of antimonious acid and phosphate of lime, with some sesqui-oxid of antimony. Dr. James was contemporary with Goldsmith, and the powder he used was probably prepared by Dr. James himself. Its action, however, is very similar to that of tartar emetic. If Goldsmith had perished from an overdose of it, his symptoms would have been vomiting, purging, and collapse.

James Beattie died of “palsy.”

Robert Fergusson, who was intemperate, died insane.

Chatterton died at 17, of arsenical poisoning—a suicide. He was driven to the act by poverty and neglect.

Falconer, the author of “Shipwreck,” was drowned by the foundering of a ship off the east coast of Africa.

Martin Luther died of “violent inflammation in his stomach.”

Cromwell died of remittent fever.

John Leyden died of the same fever in Java.

Sir Walter Scott had several strokes of apoplexy. His memory failed, and softening supervened. The end came at 61.

Shelly was drowned by the capsizing of a boat in the bay of Spezia.

Keats and Charles Wolfe, both died of consumption.

Voltaire died of strangury, probably due to enlarged prostate. Very much has been said by ecclesiastics about the agony of his last days, as though it was a judgment for his outspoken agnosticism. What nonsense! In the days of 1778, when this condition received no treatment worthy of the name, what physician would doubt but that the last days of Voltaire dying at 84, of strangury, must of necessity have been agonizing?

Galileo had stone in the bladder. With care he might have lived to shed upon that benighted time the rays of his intellectuality much longer. But he and the church differed on astronomy. Galileo asserted that the earth travels around the sun. The church would brook no such heresy. Galileo was dragged out in winter, jolted over rough roads in bad weather, to appear before the Inquisition. Exposure, imprisonment and ill usage killed him—a martyr to progress.

John Milton died at 65, of “gout fever,” or “gout struck in,” as it was called—our gout retrocedent. It is a condition in which gout leaves the joints, and attacks some internal organ.

John Bunyan rode home in a heavy rain, took a “fever” and died.

Sir Isaac Newton was long a sufferer from gout and stone in the bladder. He is supposed to have died from the latter.

Dean Swift once pointed to a dying tree, and said: “I shall be like that tree—I shall die at the top.” He had Ménière’s disease, producing paralysis, then aphasia, and finally a decay of all the mental faculties. He lived a year without speaking a word.

Edgar A. Poe was picked up in the streets of Baltimore, one morning in 1849, and taken to a hospital, where he died without regaining consciousness. His death was attributed to drink and exposure. There has always been a suspicion that he may have been the victim of an assault. Age 38.

Letitia E. Landon—“L. E. L.”—died of an overdose of prussic acid.

Washington Irving died at 76, suddenly, of disease of the heart, in his own “Sleepy Hollow.”

TO BE A DOCTOR.

BY BAYARD HOLMES, M.D.

PROFESSOR OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO, AND SECRETARY OF THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

Of all callings, medicine and surgery seems to me the noblest. What occupation can be more elevating to its followers, or more beneficial to mankind, than the alleviating of human suffering? The work is hard and the pay none too good; but the life of a medical man is active and stirring, and both the study and practice of the science have a singular fascination for those who follow it *con amore*. And not only so, but the scope of its discoveries and of its application is constantly expanding, so that there is always something new to sustain the interest. There are other professions which by the survival of a rather foolish conventionalism, occupy a higher social grade, and in which the

pecuniary return is greater, but to my mind none are so elevated and so elevating as this.—ANON.

The Choice of a Profession.—Many young men, just completing their literary education, are looking about the world for a useful and honorable occupation. Some turn to the church, and here find a field limited in its usefulness by dogmatic prejudice and by contracted sentiment of conservative congregations. Others turn to law and discover in it the most restricted freedom of thought and action and they find it a profession which presents the greatest dangers and temptations to the beginner to lead a life of grasping selfishness. Others undertake some branch of technology and find too late that the young electrical or civil engineer has but a single or only a few possible employers and that he is helpless to command reasonable compensation. Others go or attempt to go into business, only to find at last that all avenues of remunerative trade are filled by greedy corporations, that their small patrimony is swallowed up in a hopeless competition and that they themselves must become the servants of their unequal rival. A few through force of circumstances over which they have no control take up education as a life work and a part of these have those exuberant qualities and that profound enthusiasm which win success and make teaching fill a happy life.

But some will turn to medicine and surgery as the freest, the commonest and the most inspiring of all services to which a good man and true can devote an earnest life. It is free because the doctor depends on no one class of society for opportunity and support. It is the commonest because no class of society and hardly any individual can do without the services of the doctor. It is the most inspiring because it is a life of service diversified by the strongest incentives for study in a field at once scientific and social.

The life of the physician and surgeon is one of devotion. He enters into the confidence of his patient for the good of the patient alone. To him the treasures of home and the destinies of families are entrusted. He comes to his patient in sympathy. He decides upon the conditions of disease. He fixes upon methods of treatment and then he undertakes to carry out the dictates of his own judgment. He performs the function of the advocate, the expert investigator, the judge, the jury, and the executive of the law. No other single man in modern society holds such power of life and death, of health and misery as the doctor does. It is not surprising then that the career of the physician and surgeon attracts men of the highest, the most noble and the most unselfish impulses. To become a wicked physician one must needs have been either a very bad or a very stupid man. An indifferent man after years of medical practice often becomes a true and noble fellow. In no other walk of life is there such training of character, such obliteration of sham and pretense, and such incentives for the cultivation of a kind and helpful disposition.

It is worth while then to consider what sort of a young man is best adapted to become a useful and successful physician and surgeon. What sort of a body should he have? What sort of a mind should he cultivate? And what sort of an education should he pursue?

His body.—The young man who aims to become the most useful doctor should have a perfect body. He should not be lame, blind or deformed. He should

have strong and well developed hands. He should have a steady and well balanced nervous system and a cheerful, even hopeful or sanguine temperament. The doctor's life is a hard one. His time is broken, his meals and sleep are irregular. The death rate among physicians is higher than among any other class of professional man. They are more exposed than others to all contagious diseases. To endure these unusual trials the young man who would be a doctor should be free from defects and perfectly developed. It is not enough that his body be strong, it must be well-trained. The medical student should have that dexterity and common sense which an intimate contact with nature and a masterly understanding of nature's laws alone can give. He should be a handy man, ready at all times to do anything or all things. Therefore he ought to train himself in all the arts of home life. He should work in the garden and orchard, noticing every form of life, every manifestation of chemic, physical and biologic force and turning all to the use and beauty appropriate to it. He should put himself on intimate and friendly terms with all domestic animals, learning their secrets and studying their habits. He should follow the sportsman and fisherman and cultivate a quick perception and a sturdy endurance. He should row, sail and swim, climb trees and engage in sports and games of strength suitable to his years and physical development. In no one thing should he try to be first, but rather to be good in all. He should see to it that as he approaches the age of 17 and 18 years he has a proper and adequate development of the thorax, a well balanced musculature and a sharp and quick circle of nervous reflexes. He will naturally be a pretty good manual tradesman, a good carpenter, a fair blacksmith, and a respectable tailor or shoemaker. There are many things he should not allow himself to do. He should not spoil his finger joints with baseball. He should not pinch and deform his feet with ready-made shoes. He should not eat or sleep too much. He should not keep late hours. He should not have vicious habits, such as smoking tobacco, drinking whisky, spitting tobacco juice or munching candy. When this young man decides to begin the study of medicine he should not be less than 17 years old, he should not weigh less than 61 kilograms (135 pounds), and stand 171 c. high in his bare feet (5 ft. 7 in.) His chest on full inspiration should measure not less than 89 c. (35 inches), his head should measure 19.5 by 15.5 c. He should not have any heart lesion, nor any varicocele or hemorrhoids. There should be no evidence of tubercular disease of the lungs. His skin should be clean, tough and thin.

His mind.—The mental training of the young man must be based on the same broad view of life and hope for usefulness. The contact with nature so necessary for physical development is essential also to the healthy growth of the mind to self-understanding and self-mastery, and to a mastery of the outside world. The ear develops in the silence of the woods, in hunting and fishing, in the pursuit of the creatures of air and water, in the strain and concentration of critical movements in games and work. Feeling is the master sense. It grows with the struggles with nature, in play, in work and in the laboratories of the schools. Contact with nature makes a boy truthful to himself, and begets stability of character. The laws of nature are always just, and nature is never deceived, nor does she fail to punish smartly any one who tries to deceive himself.

Contact with real things, develops the real and essential qualities of the mind, curiosity and self reliance.

But the young man who would become thoroughly trained for his profession must not shun men. In all places and at all times he must be a good fellow well met with all human beings. Medicine recognizes no classes, no grades, no social distinctions. Culture, education, social or political position influence in no degree the conduct, obligations or sort of services of the true medical man to his patient. Degradation, crime, misery and unworthiness do not detract from the claims of the sick to the services of the true doctor. Therefore the young man ambitious for medical service and usefulness must early begin to fraternize with all sorts and conditions of man. He must live with all kinds of people. When he goes out for a tour on his wheel he will have ample opportunity to meet familiarly many peculiar folks. While a tire is being mended the time can be put to advantage by a talk with the village shoemaker. Every vacation should be spent thus in learning thoroughly and intimately some new phase of life. There are no more learned people than the tramps. Their acquaintance should therefore be cultivated. This can never be done except by a familiar life with them. In his own home the young man should be helpful and sympathetic. Mothers are usually wiser than fathers and more easily approached, but there are thousands of fathers whose hearts are aching for the confidence and affection of their sons. Therefore cultivate father and mother. It is a great loss to a boy to have no younger brothers and sisters to train him in self-sacrifice and helpfulness, but in other situations in the neighborhood, in the church and in the school almost the same end may be attained.

The ordinary high school course should be finished both because it will give a good preparation for college and because the boy can thus measure himself with all the boys in his community and learn to know on a common level all alike, the sons of the rich and the poor, of the cultured and uncultured.

Happy is the young man who has a real teacher during his years of preparation for college. This is perhaps the most important of his years of education in school. He is then most moved by his models and most directed by the purposes and aspirations of others. During this time his library should slowly grow. The books he loves should be put in handsome covers on his shelf. He should have the faces of a few of his heroes on the walls of his study and some good work of his own hand should be put in a place of honor. Much that he thinks good now may later be thrown into the rubbish, but for the present it is good.

During the high school course no effort should be made for high marks. Nearly all boys from ten years up to eighteen are far behind girls of their age. He should not fret or worry or get nervous during this trying time. He must do his best with a reasonable number of hours of study and let the rest of the time be put in at games and sports, at work and excursions.

Above all things he should learn to read and write English before he leaves the high school. He should prepare for college by taking Latin and Greek because these are the best acquired during early life. He should finish his high school and enter college with a full line of credits in Latin and as much Greek as he can get. In exceptional cases high schools have good teachers of modern languages and sciences, but un-

less this is the case he should take as little as possible of the time necessary for Latin and Greek for these "soft snaps" as they are often called.

The Literary Course.—In his college course he should continue one of his classics for at least two years. Probably he will select Latin. Greek is however more humane, inspiring and refining. He will find it possible now to take up a thorough study of physics, chemistry and biology. There is really no end to any one of these great fields of nature and no part of nature is unfruitful to the young medical student. It is rather the development of the scientific conscience and the scientific method than any thorough knowledge of any of these subjects that is sought for. He should select, therefore, teachers rather than subjects. If he can do advanced biologic work, especially in comparative anatomy, in physiology and in histology, it will be a real help in the professional school. Experimental psychology as taught in many universities is invaluable both because of its intrinsic usefulness and because it is a fine study of the value of evidence in observation.

Among the studies of the university years some course in sociology should be selected. Under inspiring teachers who use the seminar and laboratory method this department furnishes the basis of the most useful study. English literature and history ought also to occupy a large amount of time and study. When the mind has been prepared for historical studies by the removal of prejudice and by familiarity with all classes of men and their various lives and labors, history has a strong influence in making character. Above all things then the college course must be finished and the bachelor's degree taken. Honors should not be sought for during this course but all work should be thoroughly and well done. Something should be completed every year, some essay, thesis or investigation. Some paper should be published in the best college journal or read to a society.

When the college courses is needed and the young man is ready for the medical school, he should find himself prepared as follows: He stands well in all classes and has a good record in athletics. He reads biologic and chemic theses in German and French understandingly. He has an intense interest in some department of biology or chemistry, and a general knowledge of physics, chemistry, biology and anthropology. A few medical schools give such students special privileges, such as a shorter course—three years—or an honorarium in fees.

The Medical School.—The study of medicine now requires four years in the lecture rooms, the laboratories and the clinics of the medical college. There is no need of the preceptor who used to play so important a part in the medical education of our grandfathers, but the friendly services of an educated physician is just as valuable as ever. He will help the student select the school in which he will study and he will give him useful object lessons in those problems of daily practice, not to be learned from books nor in the school, and he will show him many interesting cases in a manner best adapted to close observation at a time when the student has abundant leisure for study and meditation.

The study of medicine is the development of knowledge of physiology, pathology and therapeutics; the living healthy human body, the human body sick, and the methods of treatment. Anatomy, histology, em-

bryology and hygiene are parts of the first, pathologic anatomy, microscopic anatomy, and clinical medicine are parts of the second; and the practice of medicine and surgery in all their divisions are parts of the third. These groups are pursued in our medical schools somewhat in the order mentioned and they consume each about a third of the time and labor of the course. Each group has a very gradual merging into the other groups and no one branch of medical study stands alone. If these three groups be represented by three overlapping circles an idea of their interdependence can be gained.

The study of anatomy seems to many at first thought very repulsive, but few men find it distasteful after the work is seriously begun. This is a branch of medicine which is well worked out and may be looked upon as relatively complete, yet there are still some dark contents even in anatomy and the ambitious anatomist will find room for adventure.

Physiology is the greatest of all the foundation studies of medicine, new discoveries are made in this department every year. Physiology is best studied by the laboratory and seminar method. Lectures are valuable also when given to students with sufficient knowledge derived from the laboratory work and from reading. Much good teaching of anatomy, physiology and histology is now done in the universities and colleges of the country. The study of pathology and therapeutics can best be carried on where many post-mortems are held and where large ambulatory and hospital clinics are to be found. The closer the student comes to the patient and the more careful he studies each case, the better able he will be to read pathology and therapeutics understandingly. The examinations for the medical degree are now usually held at the end of each year of study. Credits are given for work done and when the necessary credits are received and the necessary time spent at the school the doctors degree is granted. In some States this degree carries with it the right to practice medicine and surgery, but in other States an examination before a State board is necessary. Students of the better colleges are usually able to get the certificate to practice, a year or so before they are entitled to their degree. If the student can get his certificate before he graduates, he sometimes finds an opportunity to practice and get valuable experience. The medical course in the very best equipped schools is still very inadequate. Sometimes the student feels this deficiency. The better the student and the better he has done his work the more likely he is to feel his need of further study. The place for this further study is the hospital.

The Hospital Course—The conscientious young doctor of medicine must immediately take a course of about two years as a resident physician in a hospital. He can obtain the best position only by an examination. These examinations are usually held at the end of the school year. They are unfortunately confined to written papers. Usually these examinations are set by men who have no experience in teaching and as a result they are a poor test of fitness of the applicant for the position. Much depends therefore upon a ready wit, rapid and clear answers and an ability to detect the foibles of the examiner. It is purely a game of chance. The well prepared men are, however, at an advantage, but stuffing and cramming so disastrous to true scholarship are encouraged. Under present conditions only a small proportion of gradu-

ates in medicine can secure hospital positions. The hospital authorities do not like to board many internes and prefer to overwork them. The hospital furnishes its house staff with rooms, board and washing. Sometimes a small honorarium, a case of instruments or a microscope. All hospitals give a certificate to those who maintain a good record during the term of service. When the young interne begins his service in the hospital, he is assigned the poorest quarters, and is attached to a senior house physician or house surgeon under whose orders he works. He writes histories, takes temperatures and makes chemic and physical examinations on the medical side, or if on the surgical side, he does minor dressings. The senior is usually somewhat exacting but always helpful if his junior is not "too fresh." If he knows his place and is willing to learn he soon has the confidence of all and his mistakes in diagnosis or his clumsiness in treatment are pointed out in a friendly way. But woe unto the junior interne who feels his importance as a doctor of medicine and shows that he feels it. His errors will be held up to ridicule in season and out of season. His clumsy casts and his errors in treatment will be carried before him wherever he shows himself. His meals will be garnished with his blunders and his sleep will be disturbed by visions of his ignorance. When the junior service is over the interne has become acquainted with the rules and customs of the hospital. He usually has for the first time a clear knowledge of the more common diseases and some skill in diagnosis. The next service is one of greater independence and less drudgery. It usually consists in a term in the post-mortem room or one in the examining room. In the post-mortem room the study of pathologic anatomy is for the first time advantageously undertaken. At first there is a distaste for the monotony of the work but at last it becomes under the encouragement of the careful pathologist, almost a passion. Here is felt and seen the real lesions sought for with such imperfect success at the bedside. It will often be possible for the interne to demonstrate on the post-mortem table conditions only suspected at the bedside a few weeks before. These exercises give an individuality and vivid concreteness to ideas of disease hard to obtain in any other way. They stand to the postmortems observed as a student from the benches as a solid model stands to a picture. In the examining room again a new factor comes into the young doctor's experience. Elsewhere he has been considering disease in the abstract, disease as affecting some particular human being and diseased tissues on the table. Now men and woman come to him applying for hospital treatment. He must decide in a few moments and under rather unfavorable circumstances whether or not the man or woman is sick; if sick, then whether it is a disease or condition requiring hospital treatment. If not a case requiring hospital treatment, then what disposal shall be made of the person. Must the person be sent to the poorhouse or to a dispensary. In no other position in the hospital can an interne show himself so much a man as here. For the first time he must reckon with conditions beyond chemistry, physics and biology. For the first time he tastes practice as he will find it in the world outside books and hospitals. Now he will come in contact with hospital authorities who often are inspired with a desire to keep down the number of admissions or limit some particular class of patients. He will feel that the interests of the patients are not properly considered by the

hospital managers and little unpleasantnesses will arise of which before he has only heard fatuous rumors.

Contact with the managers of the hospital is apt to make the interne think less highly of hospitals, of his own position and of medicine and medical charities, but if he is a true man he will endure rebuff, professional contempt and heartless rulings in such a manner as to command from the hospital authorities a reluctant respect for himself, and a recognition of the ideals of professional conduct. When he begins his service in the examining room the examining doctor should tabulate for himself all the cases that require instant diagnosis and rapid institution of treatment. He must be ready in such cases to act promptly and direct in person the first treatment, thus acting for the house physician and surgeon until their arrival. As examples of these emergency cases let me mention sunstroke and poisoning by morphin. In these cases the diagnosis can often be made before the patient is removed from the ambulance and treatment can be begun at once. For his own conduct toward the patient the examining physician must make the strictest rules. Unfortunately the study of medicine abroad has brought to America foreign traditions and customs which are not to be imitated by any American. The unsympathetic and even cruel examination of patients so prevalent now in many dispensaries and hospitals is unbecoming the true doctor. Let your rules be unwritten except upon your conscience if you will but let this be the first: Every person be he diseased, though ignorant, suspicious, dirty, disgusting or cruel deserves gentleness, sympathy and fraternity.

When the interne becomes house surgeon or house physician, his responsibilities and opportunities increase. He now has charge of the wards, gives orders to the nurses, receives and discharges patients and signs death certificates. He makes rounds with the attending physician or surgeon, carries out his directions and is his first assistant on all occasions. This position develops self-reliance, loyalty and dignity; self-reliance because the house physician is chief in the absence of the attending man, loyalty because there always should exist the same relations between the interne and the attending man that exist between the doctor and his consultant in outside practice, and dignity because the house physician or surgeon has one or two junior internes, several nurses and all the patients looking to him for service, advice, direction and assistance. It is a fact that some attending men and even some hospital authorities do not have this exalted idea of the position of the house surgeon and house physician. Some few attending men at the beginning of their services are arrogant and overbearing and a few take delight in scolding and publicly humiliating a house man. But such instances are unknown among gentlemen and are rare as hospitals go. These bores must be endured with dignity, and an early opportunity should be taken by the interne in the quiet of the attending man's home for an understanding. The position is everything to the house surgeon, and he should be as diplomatic and yet so open and firm as to secure an adjustment of the difficulty. It is necessary in some cases to resign or humbly endure abuse. Such unfortunate examples of attending men are overbalanced by those who take the never ending stream of house men into their hearts and lives and homes. These attending men are always sought for. They are met by the internes at the door of the hospital.

They are relieved of the every burden possible. For them the histories are all well written and carefully digested. Chemic and pathologic examinations are made in advance and the fluff is cleared away for the serious work of diagnosis or treatment. These men find the ward, the operating room and the laboratory in order at their coming and all the surroundings adapted to the best professional work. Their cases are watched and cared for with more than necessary fidelity, and their clinical material is worked up by the house man greatly to the advantage of all concerned.

PERITONEAL SUPPORTS—(LIGAMENTUM PERITONEI.)

BY BYRON ROBINSON, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL,
CHICAGO.

(Concluded from page 565.)

The internal border of the broad ligament is where it diverges to receive the uterus. It is the junction of the lateral border of the uterus and broad ligament. This internal border of the broad ligament is very important, as it has relation to the side of the uterus and uterine artery as it courses through the internal edge of the broad ligament. The figure I chose to

Fig. 60 (after Doran, 1884) represents a diagram of the structures in and adjacent to the broad ligament. 1, framework of the ovary; 1a, simple or glandular multilocular cyst; 2, tissue of hilum, with 3, papillomatous cysts; 4, broad ligament cyst, independent of parovarium or Fallopian tube; 5, a cyst in broad ligament above the tube but not connected with it; 6, broad ligament cyst; 7, ovarian fimbria of tube; 8, the hydatid of Morgagni; 9, Kobelt's tube enlarged. Cysts 4, 5, 6, 8 and 9 are always lined internally with a simple layer of endothelium; 10, the parovarium, the dotted lines represent the inner portion, always more or less obsolete in the adult; 11, a small cyst developed from a vertical tube. Cysts that have this origin or that spring from the obsolete portion, have a lining of cubical or ciliated epithelium and tend to develop papillomatous growths, as do cysts in the tissue of the hilum; 12, Gartner's duct, often persistent in adults and animals as fibrous; 13, tract of duct in uterine wall, unobliterated portions are, according to Coblenz, the origin of papillomatous cysts in the uterus. All these structures may be seen in the broad ligament by the unaided eye.

illustrate the relation of the internal border of the broad ligament to the uterus is a diagrammatic one from Ranney, Fig. 61. The figure shows the relations of the two blades of the peritoneum to the uterus. It shows that the insertion of the ligament begins at the fundus and ends at the internal os. It is diagrammatic, as the living female does not present such figurative outline in the insertion of the broad ligament into the uterus. The figure is self-explanatory. The next figure to illustrate the internal border of the broad ligament is taken from the classical anatomist, Hyrtl. It beautifully illustrates not only the uterine artery, but it shows the perpendicular arteries in a most natural manner as the nerves follow the blood vessels, it shows the nerve routes. The above short sketch points out the one free border and the three attached borders of the broad ligament, and with the

figures will give some practical views of its use and structure.

We will now take up its anterior and posterior surface. The posterior surface of the broad ligament is that portion forming a part of the walls of the posterior pelvic peritoneal cavity. It is the surface of chief interest to the gynecologist. From Doran we will select figure No. 57 to illustrate the posterior peritoneal surface. Pelvic peritonitis is very apt to occur on this surface. The ovary projects backward on this surface. The relation of this surface to the rectum aids in enhancing peritonitis from restless motion, dilatation and contraction.

The anterior surface of the peritoneum forming the broad ligament is not so large as the posterior. It is best seen by lifting up the uterus, thus putting

Fig. 61 (after Ranney, 1883) is a diagram designed to illustrate the three minor folds of each broad ligament of the uterus and the structures which are contained between its two layers, as seen in a lateral sagittal pelvic section, cutting the ligament close to the uterus. 1, 2, 3, anterior, middle and posterior folds; R, round ligament; F, Fallopian tube; O, ovary, its anterior border lying in close contact with the peritoneum; V, vagina; D, Douglas' pouch; C, outline of cervical cavity; A, anterior layer of broad ligament; P, posterior layer of same; R, reflection of peritoneum to bladder; S, space filled up with blood vessels, nerves, lymphatics, connective and muscular tissue.

Fig. 62 (after Hodge) is a partly diagrammatic cut to illustrate a transverse section in a posterior view. It shows the relative positions of the peritoneal and subperitoneal tissues and structures. The subperitoneal space is well shown. Both subperitoneal and peritoneal surfaces are equally important to the gynecologist. A few still hold to pelvic cellulitis as the chief disease, but natural pathology indicates that the first, primary and chief disease is peritonitis, and secondly, by inversion by contiguity, cellulitis.

the double blades on a stretch. It is in relation with the bladder and to some extent with the ureter. Both anterior and posterior surfaces of the broad ligament are free in their whole extent. The contents of the broad ligament are closely related to the folds covering them. In fact, so closely related are the ligaments and their contents that they should be discussed together. It must be remembered that the mesosalpinx and the broad ligament are not identical. The broad ligament is larger than the mesosalpinx. The mesosalpinx is a triangular double-bladed membrane, its base is directed toward the side wall of the pelvis, while its apex points to the uterus. The mesosalpinx

is bounded above by the Fallopian tube, below by the ovarian ligament and the ovary, externally by the tubo-ovarian fimbriae and the ligamentum infundibulo-ovaricum of Henle. Its apex points toward the uterus. This triangular double fold of peritoneum is the mesosalpinx, the ala vesperilionis or the middle fold of the broad ligament. It is only a part of the broad ligament:

The contents of the broad ligament are:

1. The Fallopian tube.
2. The ovary and its ligament.
3. Parovarian.
4. The round ligament.
5. The uterine and ovarian arteries.

Fig. 63 (after Hart and Barbour, 1883) represents the broad ligament cut to show its contents: f, Fallopian tube; e, ovary; d, broad ligament cut near the side of the uterus. In this cut surface one can note the shape and contour of the ligament, marked d, and also contents, blood vessels, connective tissue and nerves; b, shows a sliced surface of the bladder; a, vagina.

Fig. 64 (after Savage, 1880) is a figure intended to show the relations of the female pelvic organs with the pelvis and with one another. It is a horizontal section of the abdomen immediately above the iliac crests and behind between the last lumbar vertebra and sacral, about an inch above the pubes, and shows well a superior view of the pelvic organs with their peritoneal folds. U, uterus; B, bladder; O, ovary; T, Fallopian tube; M, urachus; L, round ligament; R, rectum; V, vertebra; G, ureter; C, utero-rectal ligaments; A (in front), obliterated remains of hypogastric arteries and A (behind), spermatic vessels.

6. The plexus pampiniformis.
7. Muscular and connective tissue.
8. Lymphatics.
9. Nerves.
10. Remnants of urinary organs and germ epithelia.
11. The ureter to a varying degree in different individuals.

The intimate relations of every one of the above eleven structures to the broad ligament folds in disease is sufficient to call attention to both ligament and structures at the same time. When the peritoneum covering the contents of the broad ligament is infected the consequent inflammation may spread to

any and all the structures. Infection which produces broad ligament peritonitis may produce parovarian cysts, phlebitis, and straighten out and dilate the vein. It may infect the ovary, causing cystic degeneration or lymphangitis. In some fifty bodies which I have examined carefully I found that old pelvic peritonitis had involved the connective tissue in the broad ligament, producing veritable cellulitis. Such bodies showed pelvic cellulitis in about 10 per cent. In some, cellulitis was so severe that the ureter had, during contraction and dilatation, while the soft exudate existed, tunneled out a hole and held it firmly and stiffly open. Myoma may develop in the broad ligament. The utility of the broad ligament as a peritoneal fold may be enumerated as:

1. It is a bed for structures.
2. It preserves the definite relations of its contents.
3. It holds its organs so related that function coördinates, *e. g.*, tubal peristalsis and ovulation are so coördinated by the ligamentum ovaricum that the ovum is definitely carried into the uterus.
4. The broad ligament acts as a guy rope to the uterus. It is a secondary uterine support. However, its chief office is to transmit and sustain structures.

Fig. 65 (after Savage, 1880) is designed to show the sacro-uterine, or better, recto-uterine, ligaments. It is an excellent diagram, in which the uterus is drawn well downward in the vagina by a volsellum forceps. The noticeable features in the figure are the peritoneal folds posterior to the uterus, as AA, spermatic vessels GG, ureters, and CC, recto-uterine ligaments; B, bladder; U, uterus; R, rectum; V, vertebra; O, ovary; T, Fallopian tube (fallopian); L, round ligament. The proximity of the ureters, GG, to the uterus, should be ample warning to surgeons in operative procedures. This figure merits attention. It shows the mechanism of the structures supporting the uterus and opposing its displacement.

The sacro-uterine ligaments or utero-rectal ligaments are the chief uterine supports. They are known as the folds of Douglas. These folds contain muscular fibers and were called by Luschka retractores uteri. The muscular fibers which they contain are a continuation of the vaginal walls, so that the vagina and the utero-sacral ligaments together form a supporting beam on which the uterus rests. The folds of peritoneum are well seen in the figure which accompanies the text, taken from Savage. Many dissections have convinced me that the utero-rectal folds of the peritoneum are the chief supports of the uterus, especially prolapsus uteri. They are very strong folds. These folds are subject frequently to a chronic inflammation which shortens or thickens one or both. The disease of the ligaments seems to be due to a slow, progressive, infectious process. By practicing traction on the uterus it is plain to observe in the cadaver that the main tension falls on the peritoneal folds known as the utero-sacral or, better, utero-rectal ligaments. They are primary uterine supports.

Minor peritoneal supports or ligaments will be de-

scribed with the visceral tracing of the peritoneum. The pelvic peritoneum is thrown into frequent folds which are accompanied by peritoneal pouches. Hodges' diagram, Fig. 62, shows the folds well. Here the peritoneum like a sheet is spread over the pelvic viscera and its folds tuck themselves in between the visceral clefts. The peritoneal ridges indicate the presence of organs projecting upward from below.

Special characteristics of the pelvic peritoneum are

- a. Elasticity.
- b. Capacity to resist infection and trauma.
- c. Thickness and strength in the female, over that of the male.
- d. Numerous folds and pouches.
- e. Extensive subperitoneal areolar tissue bed.
- f. The wide range of motion that the peritoneal attachments allow the pelvic viscera.
- g. An opening in the pelvic peritoneum in the female.

IMPROVED HYPODERMIC SYRINGE AND REMEDY CASE.

Read by title in the Section on Practice of Medicine, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY ELMER LEE, A.M., M.D., PH.B.

CHICAGO.

In these utilitarian days, that which comes the nearest to the urgent requirements of the practicing physician during the hours of the day and the visits of the night, in the way of supplying remedies for emergencies, is the desire of practical physicians. There are times when drug stores are inaccessible, and there are times when there is not a minute to spare between the arrival of the doctor and the demand for immediate action, which make it imperative that remedies should be carried by the physician.

The present hypodermic case, which is for the first time brought before your attention, is not only a hypodermic case, but is also an *emergency* case. It contains a hypodermic syringe of the simplest, and, in my opinion, the best pattern that has ever been made. The syringe is light, it is cleanable, it is inexpensive, it is effective. These are qualities that are to be desired. The syringe is made of glass for the barrel, and hard rubber for the fittings. The needle points are attached to hard-rubber butts which fit the nozzle of the syringe without a thread. This is the simplest form of connection between the needle and the syringe, and it is the best one. The syringe that accompanies this case is durable and sufficiently strong for every purpose for which a hypodermic syringe is intended. It is sufficiently inexpensive, so that instead of having the syringe repaired when a part is broken or lost, it may be replaced at a cost not likely to exceed that of repairing an ordinary syringe. The syringe is placed in the middle of the upper half of the plate on which are arranged the glass tubes containing the tablets. The needles are held in a short glass tube in the middle portion of the lower half of the metal case. On either side of the syringe and the needle tube are spaces for thirteen tubes of hypodermic tablets and one glass tube in which are contained the brass wires for keeping open the needles. These hypodermic tablet tubes lie in regular order and are in sufficient number to provide medication in any instance where a physician may require such medicaments. In addition to serving as medicaments to be used with the hypodermic syringe, they

form, equally well, remedies which may be administered by mouth, thus constituting a remedy emergency case. This is very desirable, for in the present day patients look more and more to the physician during his visits to supply them with temporary remedial aid, and it is a very effective measure for the physician to take from the case carried in his pocket suitable tablets and leave them with proper instructions for the use of the patient. It not only gratifies the caprice of patients, but it is indeed a very useful measure, and one that begets a friendly sympathy from the patient in behalf of the doctor. The patients are eager to be served quickly, and if the doctor has a suitable case of remedies upon which he can draw temporarily, it is fortunate for the patient, and will give the doctor himself considerable satisfaction.

In addition to the hypodermic syringe, the needle bottle and the tube of hypodermic tablets, a place has been arranged on the outer edge of the metallic case for a fever thermometer, which is held in place by a suitable arrangement. It has been proven by experience and usage as not likely either to fall out of its place or to get broken any more than it would if

its protection. In the leather case there is a pocket which is intended so carry an envelope which may be supplied with surgeon's silk and needles and perhaps a few small pieces of adhesive or court plaster; or the pocket may be used to contain any other articles that are not bulky, which the physician may elect.

This combination of hypodermic tablets and thermometer constitutes a small yet ample emergency or remedy case, which may be carried in the upper vest pocket at all times and under all circumstances. It is attractive in appearance, light in weight, and contains enough tablets to meet almost every variety of emergency calling for immediate remedies.

The glass tubes, the syringe and thermometer are held in their places against the metal back by elastic rubber bands. These bands are of no particular kind or quality, and if one should give out, as anyone knows, a rubber band can be easily and quickly procured in any community, and the broken one can with little or no trouble be replaced. Various friends have suggested that a better substitute for the bands would be another metallic covering for the front of the case; others have suggested that there might be a

carried in any other manner in the pocket. The addition of the thermometer was a later thought in reference to the perfection of the case, and has pleased me a great deal in being able to have a thermometer so accessible and at the same time avoid carrying an additional piece of furniture in my vest pocket. The case is intended to be placed in the upper vest pocket, and supposed to have the exclusive use of whichever pocket it has been assigned to by the doctor who wishes to use it.

The case consists, as may be seen, of a sheet of aluminum with crimped sides and folded ends in order better to serve the purpose for which the case is intended, as well as to give additional strength. Then there is a partition between the upper and lower half, in the middle, which serves as a rest for the row of bottles and the syringe. The divisions for the tablet tubes are made by metal posts screwed into the aluminum back and riveted, so that they are secure and durable. The weight of the case is so inconsiderable that it is a source of surprise that so many remedies, including the thermometer and syringe, can be carried with so little inconvenience.

The hypodermic case fits into a leather pocket for

narrow strip of metal passing from one side of the case to the other and fastened with a clasp; another has suggested that instead of using the little posts that are fastened into the back of the case that spring clasps such as are used in some hand cases would do away with the necessity for using the rubber bands or any other method of holding the contents of the case in their places. Now all these suggestions, together with others, are not considered equally good as the simple device of holding the tubes in position by the elastic rubber band. This is sufficiently practical as I know from experience, and it is the most inexpensive and most aseptic method, and at the same time it is the simplest way; and in these days when we are looking to the practical and utilitarian side of every new proposition that promises improvement, simplicity and economy of space are imperative. Now after a great deal of reflection, and having considered the many interesting suggestions of medical friends, it is my conclusion that there is presented in this case, for the use of my colleagues, a series of useful features which surpass any similar provision of which there is any knowledge. We all know how awkward it is to be in the presence of emergencies requiring remedies

and not have our hypodermic case with us, or any remedies at hand; and we all know how vexatious it is to have a hypodermic syringe, at the moment when it is desired to use it, the packings dry and the syringe fail to work; but it must be remembered that any instrument, whether it be a syringe or not, must be kept in working order, and that means that it must receive its proportionate amount of attention; and if this simple syringe receives a very little attention it will last a long time and remain in condition for immediate use as long as any other syringe, and if it is lost or broken it is so inexpensive that it can be replaced at a trifling cost.

The division posts in the metal case have been located especially with reference to taking tubes of a uniform size, such as are made by Parke, Davis & Co. The case, including its leather covering, is shapely, and sufficiently light, not being thick or bulky, it may be easily and naturally carried in the upper vest pocket, at all times providing us with a great variety of useful and convenient remedies.

NEW INSTRUMENTS.

A KNIFE PROTECTOR.

BY C. A. VEASEY, M.D.

Adjunct Professor of Diseases of the Eye in the Philadelphia Polyclinic;
Chief Clinical Assistant to the Ophthalmological Department
of the Jefferson Medical College Hospital; Consulting
Ophthalmologist to the Philadelphia Lying-In
Charity Hospital, etc.

Almost everyone who has had occasion to employ a Graefe cataract knife or a keratome, has at some time or other had the misfortune to have had the point blunted or the edge dulled by coming in contact with the sides of the dish in which sterilization was being performed, either while the instruments were being sterilized or while the dish containing them was being moved.

If one has a rack in which to place all of the delicate cutting eye instruments the above misfortune is not likely to occur. But as a rack is not always to be had when needed, the author has devised an instrument shown in the accompanying diagram, so small as to be easily carried in the instrument case, which will protect the point and edge of the knife while being sterilized or moved about prior to the operation.

The device is so well shown in the diagram that any detailed description would be superfluous. Suffice it to say that it consists of a body, the sides of which are sufficiently high to protect the edge of the knife, extending from which we have an arm for the support of the knife handle, the latter being held firmly in position by a double spring. It is made from one piece of metal so that it can be completely and quickly sterilized.

The keratome protector is made similar to the above, the only difference being that its sides opposite the blade are sufficiently high to protect the edges and point of the largest keratome.

I am indebted to Messrs. Charles Lentz and Sons, of this city, for their assistance in perfecting the device and for the above cut, from whom the instrument may be obtained.

47 North 17th Street.

SELECTIONS.

Operations for Prostatic Hypertrophy.—Our foreign exchanges all contain articles on this subject, recommending some the resection of the vas deferens, others castration, and still others merely the subcutaneous section of the vas deferens. Each reports cases of relief and cure, some of them almost miraculous. The last mentioned operation has not been performed on many persons yet, but theoretically it answers the purpose completely, as experience tends to show that all that is necessary to reduce the hypertrophy of the prostate gland is to sever the vas deferens in some way; it is suggested by Lauenstein, of Hamburg, in the *Centralblatt f. Chir.*, February 15. Guyon describes some experiments on dogs in the *France Méd.*, 1895, 43, and states it as his belief that the results of these operations are due to the diminished congestion brought about by reflex means. He found that the prostate gland responded more rapidly to resection of the vas deferens than to castration in his experiments on dogs.

Experiments on the Secretory Excitability of the Alimentary Canal.—Dolinsky has been making a series of experiments on dogs carrying pancreas and stomach fistulas, which show that the secretions of the pancreas are stimulated when the lining of the duodenum comes in contact with acids—diluted vinegar acid, mineral acids, lactic acid, or sour drinks (kwass), etc. It also affects noticeably the secretion of the gastric juice. Alkaline liquids do not produce it, nor neutral liquid foods, when the latter are introduced without the knowledge of the animal, as this always stimulates the secretion of gastric juice. Special experiments with dogs who had, besides the two fistulas, an opening into the esophagus, showed that the psychical effect of giving food, even when the animal was deceived with pretended food, was to excite the secretion of gastric juice, the hydrochloric acid of which stimulated in turn the secretion of the pancreas. Dolinsky considers these facts important in a teleologic sense, as the alkaline secretion of the pancreas neutralizes the acidity of the gastric juice. Fats also excite a reflex pancreatic secretion, and alcohol in a slighter degree. *Centralblatt f. Chir.*, February 8.

Is Surgical Intervention Warranted in Primary Renal Tuberculosis?—This question was the subject of an able address delivered before the last French Medical Congress, by Dr. Pousson, the well-known surgeon. He first described the different methods of invasion in primary and secondary infection, as the bacilli locate in the vascular zone of the organ in the former case, and produce the phenomena of congestion, pains and hematuria. Secondary infection attacks the zone of the pyramids and is a mixed process starting in the bladder, and revealing its presence chiefly by suppurative lesions, or pyuria. The hematuria is often the only symptom of infection for quite a while, and he cites many cases where it persisted alone for months. Here he thinks surgical intervention entirely uncalled for, as this form is not exposed to complications from other infections, owing to the isolated position of the organ. Only when it is accompanied by severe pains preventing rest, or excessive, weakening hematuria, which forces the hand of the surgeon, as it were, is a surgical operation legitimate, and nephrectomy indicated. In all cases where the other organs seem to be exempt, he agrees with the majority of French physicians, that local attempts to exterminate these bacilli from the system are apt to be fruitless and followed by their reappearance there or elsewhere.—*Archives Clin. de Bordeaux*, January.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, MARCH 28, 1896.

NATIONAL BOARD OF HEALTH.

Information comes to us from New York that the State Board of Health is aiding in a movement to secure the reestablishment of a National Board of Health, believing it to be for the best interests of the various States, in warding off invasion of epidemic diseases. Secretary B. T. SMELZER, M. D., has received a letter from the aged Dr. STEPHEN SMITH, of New York City, as chairman of a sub-committee of the New York Academy of Medicine, which is considering a bill to be laid before Congress upon the matter.

Dr. SMITH says an effort is being made to secure the united action of all medical organizations interested in such legislation on the proposed bill, which has been prepared by the committee of the Academy. When this bill is matured and approved by the profession it is proposed to make it public and invite the coöperation of all the friends of the measure to secure its enactment by Congress.

One feature in the proposed bill is said to include a provision to have a representative member of the profession and of this National Board who shall be a Cabinet officer.

We suggest to the distinguished sanitarian that he print the proposed bill in the JOURNAL now, so that the members may read and discuss it.

THE SURGICAL TREATMENT OF EPILEPSY.

Surgical operative interference for the relief of epilepsy is probably less popular at the present time than it was a few years ago. The utterances of high authorities like AGNEW and others condemning or rather discouraging the practice, and the well-merited criticisms of many of the reported successes have

markedly diminished the enthusiasm that existed with the dawn of modern cerebral surgery, in regard to the operative treatment of this ailment. It would, however, be altogether incorrect to say that the operation of trephining for epilepsy is a thing of the past, for reports are still frequent in medical literature. An article by Dr. E. G. MASON in the *Medical News* of March 21 is in evidence of this. The writer takes the view that trephining for epilepsy is a "rational procedure and has come to stay," limiting, however, the operation to well-selected, favorable cases, presumably those in which the convulsive attacks have been of comparatively recent traumatic origin. He does not specify this, however, but expressly says: "If there is evidence of a trauma in a position corresponding to the initial symptoms of the fit, an operation is usually justifiable." This is the only statement he offers that approaches a positive recommendation, and it would evidently only apply to a small proportion of cases. The results he claims as indicated by statistics, are the cure of a small percentage, a somewhat larger percentage improved, and temporary cessation of fits in almost any case.

Even a remote possibility of the cure of such a morbid condition as epilepsy would, in the opinion of many, justify the operation, while admitting for it a certain actual danger to life. To properly estimate its advantages, however, more than the mere apparent results must be taken into consideration. The cure must be rationally connected with the operation and its possibility without it must be excluded. While Dr. MASON takes a rather reasonably conservative view of his subject and recognizes the possibilities of mistakes, he evidently is inclined to give the operation all due credit and may possibly be carried away to some extent by his predilections. A certain small number of cases of epilepsy are apparently cured by drugs, another very minute proportion seems to have a spontaneous cure, and cases have been reported of recovery after various operations other than those upon the brain. Any and every procedure that makes a strong mental impression, whether it be a seton in the neck, a change of doctors, drugs or of locality is likely to be followed by a more or less temporary modification of the symptoms, which might easily, following the common practice of many of the reporters of cerebral surgery, lead to the erroneous diagnosis of a cure. While it is probable that most, if not all of the 4.3 per cent. of recoveries he finds after operation are genuine cures, it would be more satisfactory in estimating the value of the operation could we be absolutely sure no other factors had intervened. It is worthy of note in this connection that the only one of the twenty-six cases he tabulates with his paper, that is reported cured, is that of a child, 12 years old, one of a class in which the bromid treatment is sometimes strikingly successful. If there are any

cases which can be considered more amenable to treatment of all kinds than others, a certain proportion of those of young children in whom the epileptic habit has not become fixed and the development of the nervous system is still partly in the future, may properly be counted among them.

The proportion of cures of, or rather of recoveries from, epilepsy, is probably larger than is commonly estimated by the medical profession. Some individuals have epileptic attacks at certain periods of their lives which cease spontaneously and never recur, others have a single isolated attack, due to a special temporary cause. These facts must be kept in mind in estimating cures of this symptom with any treatment, and the rarity of recovery after operation is such that it suggests a comparison with these hardly less frequent occurrences. Any interruption of the attacks may in some instances give a needed opportunity for repair to the irritable cortex, whether this interruption be due to a surgical operation or to any other cause whatever.

While the results of the surgical treatment of epilepsy are not brilliant and a certain reserve is at least judicious in estimating the best of those reported, there is enough of a possible utility in surgical interference in special selected cases to yet prevent the practice from becoming altogether obsolete. In recent traumatic cases, especially in young subjects, it may be admitted as a justifiable operation. Any operation, however, not absolutely necessitated as a last resort for saving life, the statistics of which give, as in this by DR. MASON's showing, a larger percentage of mortality, small as this may be, than of cases in which it is effective for good, can not be regarded as a triumph of surgery.

THE PHAGOCYTIC ACTION OF GIANT CELLS IN TUBERCULOSIS.

The nature and the significance of giant cells, found in many pathologic conditions, but especially in tuberculosis, have not been satisfactorily determined. The results of elaborate investigations concerning these structures do not agree. The opinions that at present obtain concerning their significance may be divided into two groups. Thus WEIGERT¹ and BAUMGARTEN² believe that giant cells (in tuberculous foci) represent a partial necrosis of cells in the act of proliferation. The tubercle bacillus in the interior of the cell exerts sufficient stimulus upon the nucleus so that nuclear division may occur, but a division of the cell body does not take place because it has suffered necrosis under the influence of the bacilli. For the same reason the bacilli in the giant cells are found in the vicinity of the nuclei; the part that is not nucleated contains but few or no bacilli because the soil of this, the necrotic district, has been exhausted. METSCH-

NIKOFF, on the other hand, maintains that the giant cells have considerable vitality and play an active part against the tubercle bacilli. He claims that there exists a definite relation between the course and the duration of tuberculosis and the phagocytosis of giant cells.³ METSCHNIKOFF interpreted certain appearances on the part of tubercle bacilli enclosed in giant cells as indicating the gradual destruction of the bacilli, and this belief was supported by KOCH in his large work on the etiology of tuberculosis. STSCHASTNY,⁴ SOUDAKEWITSH⁵ and KLEBS⁶ all side with METSCHNIKOFF. KLEBS regards the giant cells as peculiar tissue formations that serve to protect the organism. Quite a discussion has been carried on between the supporters of these two diametrically contradictory views. WEIGERT⁷ regards the destruction of bacilli in the interior of the cells as not proven. The finding of dead bacilli and masses traceable to them in the giant cells does not prove phagocytosis on the part of the latter. And BAUMGARTEN⁸ concluded from his elaborate studies that the bacilli in the interior of giant cells do not show the slightest indication of disintegration. He believes that METSCHNIKOFF in his experiments employed cultures that contained bacilli of diminished vitality.

With these contradictory interpretations before him WELCKER⁹ concluded to re-investigate the whole question according to the methods employed by METSCHNIKOFF¹⁰ and STSCHASTNY,¹⁰ but avoiding the objectionable features criticised by BAUMGARTEN and others.

METSCHNIKOFF's observations were based, in part at least, upon experiments made by injecting tubercle bacilli into certain animals closely related to our gophers—the *spermophilus guttatus*. These gophers were thought to be especially refractory to tuberculosis, but it subsequently turned out, as shown by WELCKER's new experiments, and already explained by METSCHNIKOFF,¹¹ that the gophers are comparatively insusceptible to avian tuberculosis, but not to human, falling ready victims to the latter, and that METSCHNIKOFF had employed cultures of avian tuberculosis in his work. WELCKER consequently had to repeat the gopher experiments with the bacilli of avian tuberculosis in order to be able to test the results of METSCHNIKOFF. Simultaneously with these experiments he carried along a second similar series, using the bacilli of human tuberculosis. WELCKER planned these experiments so that some light might be thrown also upon the mode of origin of giant cells, and the question of their power of independent motion and of inclusion of foreign bodies. The same quantity of young, luxuriant pure growths of avian and human tubercular bacilli was injected into the abdom-

inal cavity of the same number of gophers. After a varying length of time the animals were killed and fresh, warm pieces of various organs, especially of the liver and the spleen, were examined microscopically upon a warm stage at the temperature of the body. Pieces from the different organs were also fixed and stained according to the best modern methods.

The general results obtained from these two series of experiments may be summarized as follows: After the injection of pure cultures tubercles develop in the same manner in the omentum of the animals of both the series and then, after a few days, in the liver and spleen. While the gophers treated with human tuberculosis show a process that gradually increases in intensity and accompanied with multiplication of the bacilli, those treated with the avian form present tissue changes that do not pass beyond a certain limit. The stimulus of the avian tubercle bacilli and their toxic products seems to exhaust itself, necrosis does not ensue in the foci of proliferation and emigration, and there follows a gradual involution of the tuberculous areas.

The first change observed after the injection was a small accumulation of leucocytes and then followed a proliferation of the fixed tissue cells recognized by finding karyokinetic figures in the connective tissue and endothelial cells. The epithelioid cells of the tubercles could readily be traced to the proliferating fixed cells, but also to large leucocytes. The presence of giant cells could be positively demonstrated on the fifteenth day after the injection. The size and the shape of the giant cells were found to vary very much. The same remark also applies to the number, the size and the shape, as well as the arrangement of their nuclei. In their interior there was found occasionally leucocytes, tubercle bacilli in rather small numbers, and also yellowish, sausage-shaped bodies. As regards the origin of the giant cell WELCKER concludes that they are formed by a fragmentation of the nucleus of an epithelioid cell, while the protoplasm of the cell continues to grow. At the same time he was not able to definitely exclude the possibility of their arising from the coalescence of several epithelioid cells because occasionally appearances were observed in which the outlines of individual cells could still be recognized. There were no conclusive evidences noticed of karyokinetic division of the nuclei of giant cells.

Active, independent motion was not observed to occur in the living giant cells examined on the warm stage and the examination as regards this point was very thorough indeed. It will be recollected that METSCHNIKOFF claims that giant cells are capable of ameboid motion and that he looks upon this as an evidence of their phagocytic action. This claim is consequently not supported by WELCKER's results. METSCHNIKOFF also claims that the phagocytic action

of giant cells is shown by their containing, in their interior, bacilli tubercle that present peculiar changes of form and of staining reactions—changes that he believes are due to the action of the cells. WELCKER found similarly changed bacilli in the interior of the epithelioid and giant cells of the tuberculous organs of the gophers he experimented with. Strangely enough, he found also that these peculiar, glistening, sausage-shaped masses give the iron reaction with sulphid of ammonium or ferrocyanid of potassium and hydrochloric acid. He believes that these bodies represent tubercle bacilli that have been changed as a result of cellular activity, but he can not definitely exclude the possibility that these evidences of degeneration occur in bacilli that have been acted upon by other not well understood, extra-cellular influences. It is consequently not proven that, in experimental avian or mammalian tuberculosis in gophers, the tubercle bacilli are destroyed directly by the activity of the cells and that a struggle takes place between the cells and the bacilli. WELCKER was not able to find the products of altered tubercle bacilli referred to in tuberculous material from other sources than gopher tuberculosis. Material from various sources, such as the skin of lupus, was examined with negative results as far as this point is concerned. The principal conclusion to be drawn from WELCKER's investigations are that certain gophers are very susceptible to mammalian tuberculosis, but relatively immune to the bacilli of avian tuberculosis; that giant cells are formed in the main from epithelioid cells whose nuclei have undergone fragmentation; that the giant cells in the tuberculous foci of gophers do not possess ameboid movement; and that the power of giant cells to destroy tubercle bacilli is not definitely demonstrated, although they frequently contain altered and apparently dead bacilli. The function of the giant cell in tuberculosis is consequently not well understood.

A VOICE FROM THE PAST.

In connection with the attempt being made by the medical officers of the Navy to obtain the same rank, pay and emoluments as the medical officers of the Army, in which they have received the unanimous support of the AMERICAN MEDICAL ASSOCIATION, the AMERICAN ACADEMY OF MEDICINE, and the ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES, the subjoined letter to a former Secretary of the Navy, written eighty years ago and signed by the senior line officers of the Navy, the heroes of the war of 1812, will be of interest to the members of the medical profession. The hearty indorsement of the claims of the medical officers of the Navy to consideration, the generous appreciation of the value of their services, the unqualified recognition of their military status, and the declaration "that justice requires they should, at all events, receive a compensation and rank equal to

what has been enjoyed by the medical officers of the Army," by these men whose names are historic, ought to shame the youngsters, who, as partisans in the wretched line and staff dissension which to-day disgraces the Navy, are seeking to deprive the officers of the Medical Corps of the rights, privileges and dignities of military rank, relegating them to a position of inferiority to the youngest graduate of the Naval Academy, denying them authority even in their own department and according them only an undefined "disciplinary control" over their own subordinates.

It puzzles a soldier's, as it does a citizen's, comprehension, why the medical officers in the U. S. Marine Hospital Service, like those in the U. S. Army, should *command* the commissioned and non-commissioned officers, men and employes of the Hospitals to which they are detailed, while the medical officers of the Navy are only ordered "*in charge of*," even such superb institutions as the U. S. Naval Hospitals at New York, Norfolk, and Mare Island, where the military personnel of officers, seamen, marines and employes numbers several hundred persons.

It is earnestly hoped that the members of the medical profession, who are in the Senate and House of Representatives of the present Congress will insist that justice shall at last be done this well-deserving and long neglected body of their professional confrères; and it is also the duty of the military medical men all over the United States, who are prominent members of every soldiers' and veteran organization in the country, to demand of their several representatives in Congress that the medical officers of the Navy shall be put upon precisely the same footing in rank, privileges and pay as their colleagues in the Army. It is time to put a stop to the puerile quibble that medical officers are only in or with the Navy but "not of the Navy," and therefore are not entitled to rank and equal privileges with the line—that they are only auxiliary and non-essential, and to the studied disparagement of them as non-combatants, in face of the statistical fact of their proportional losses by casualties in time of war.

The memorial of the line officers of the Navy at the time of the famous victories of the second war with Great Britain is as follows:

NEW YORK, May 16, 1816.

SIR. We have heard with pleasure, that it is the intention of the medical officers of the Navy, to address a respectful memorial to you, requesting that measures might be taken by the Department to obtain for them a definite rank in the service, an increase of pay, and the establishment by law of the rank of hospital surgeon. It has also been suggested to us that the opinion of the senior officers of the Navy on the justice and expediency of these claims, might not be without benefit. We feel it, therefore, as a duty incumbent on us to state, that we consider the Medical Department of such great importance to the Navy of our country, that no reasonable measure ought to be omitted, which could have a tendency to retain in the service the professional ability of these gentlemen, who, by their experience, knowledge, zeal and humanity, have procured

the esteem and confidence of those with whom they have been associated; and we also beg leave to express our belief that no reasonable inducements would be objected to by Congress, to procure for those who are engaged in a perilous service, and who are constantly exposed to the diseases of all climates, the best medical aid the country affords.

To effect this it must be obvious that the rank and pecuniary emolument of medical officers ought to bear some proportion to what gentlemen of professional eminence would be entitled to in private life: and we consider that justice requires they should, at all events, receive a compensation and rank equal to what has been enjoyed by medical officers of the Army. * *

* * * * *

With the most profound respect, Sir,

Your obedient servants,

SAMUEL EVANS,
JOSEPH BAINBRIDGE,
S. ANGUS,
JAMES RENSHAW,
GEO. W. RODGERS,
JAMES T. LEONARD,
EDWARD TRENCHARD,
JAMES JONES,
L. WARRINGTON.

To the HON. BENJAMIN W. CROWINSHIELDS, Sec'y Navy.

A similar paper, dated Dec. 13, 1816, in almost the same language and addressed as above, received the following signatures:

WILLIAM BAINBRIDGE,
ISAAC HULL,
D. D. DEACON,
ALEX. W. WADSWORTH.

EXTENSION OF HOSPITAL CORPS DRILL IN THE ARMY.

Of late there has been a marked activity in the Medical Department of the Army, the tendency of which is specially directed toward increased efficiency in field service. We may note, for instance, the recent modification and improvement in the hospital corps pouches, the disuse of the heavy and useless side arms with which the men were encumbered, the adoption of a new litter weighing six pounds less than the old one and the convention of a board to remodel the Drill Regulations. Were a similar activity manifested by the other War Department bureaus we might be warranted in concluding that a prospect of war was operating as a stimulus. It is true that the Ordnance Department is always progressive, that the Commissary Department is considering an "emergency ration" and that the other bureaus are active in their special lines; but nevertheless we understand that, so far as the Medical Department is concerned, this progress in the direction of efficiency for active service is no transient exhibition of energy in view of imminent possibilities, but a steady advance on well matured plans for the improvement of the Corps. We are led to make these remarks by the publication of the 13th inst. of an order from Head Quarters of the Army requiring all enlisted men of the army to be drilled by their company officers in litter-carrying and in the methods of rendering first aid to the sick and wounded; and by the same order the surgeon of the post is called upon to

thoroughly instruct such captains as may volunteer therefor and all lieutenants serving with troops in the professional knowledge required. Up to this time Army Regulations directed that four men from each company should be so instructed. These men were called company bearers and their duties were to aid the sick and wounded until relieved by members of the hospital corps. Some energetic medical officers have already succeeded in instructing most of the men at their posts by having the company bearers relieved by fresh men as soon as they were proficient in their duties. We print the recent order on another page.

THE ATLANTA MEETING.

During the past week, the Editor made a trip to Atlanta to become acquainted with the arrangements for the coming meeting, and after an interview with the chairman of the Committee of Arrangements, Dr. W. F. WESTMORELAND, he became satisfied that the Sections would be well provided for, and that the hotel space would be ample to meet the requirements of the members. Owing to the elevation of the city (1600 ft.) the heat is never great, even in midsummer, and all may expect a pleasant climate. The good people, with that generous hospitality for which Georgia has ever been famous, propose to give the members of the ASSOCIATION a barbecue which will rank with the famous clambake at the Newport meeting.

The arrangements are now complete for the JOURNAL special train, which will carry PRESIDENT COLE, the Trustees and others, direct from Chicago to Atlanta. The "Big Four," "Queen and Crescent" and "Southern" Railways, have been selected as the route of the JOURNAL special, and as said in commercial circles, "none others are genuine." The equipment of this special is as fine as the Company can furnish, and we are sure that our fellow members will be satisfied with the comforts provided for them on the JOURNAL train. This train runs on its own time and will make very few stops. It may be joined at Indianapolis or Cincinnati by sending notice to this office. The rates of fare are uniform from all points, one fare and one third. Please send on your name without delay, if you intend joining us.

Patrons of the JOURNAL special train may be assured that whatever of advantage accrues is in the interest of the ASSOCIATION treasury.

One physician in Chicago, because a pass was not promised for his wife, makes terms with another route whereby his family may have a pass, in consideration whereof he circularizes the profession generally, and advises them to go with him. A drug firm in another city running a medical journal in Chicago, also proposes to send out a special train in the interest of their enterprise. Whether the JOURNAL ever runs another special to any of the meetings depends upon the view the members take of it.

CORRESPONDENCE.

Ophthalmology.

To the Editor: In the editorial of March 21 entitled "Ashamed of What They Should be Proudest of" the patriotism of the writer has apparently obscured his meaning in some respects. We who practice the art are of course proud of the achievements of American Ophthalmology, and heartily believe that we can do as good work and often do better work, in securing the highest degree of visual acuteness possible for our patients; still it may be doubted if all the strictures and epithets used by the writer in any respect add to the fog-penetrating power of the "eagle's scream." The particular things of which ophthalmologists should be "proudest of," are not very definitely stated, but the implication is that the writer refers to the discovery (?) of the great importance of the eye muscles in producing "eye-strain," blepharitis, trachoma, cataract, and "numerous other ocular ills." As there undoubtedly exists a considerable diversity of opinion upon the whole "muscle business," perhaps he can tell us the particular advances which merit the display of our pride. For example, does he think that coördination of the movements of the eyes in looking at objects, is different from, or differently governed from muscular coördinations elsewhere, as in walking, writing, playing the piano, etc.? Does he think that a "tendency" to imperfect coördination as indicated by the expressions, heterophoria, esophoria and exophoria, is worthy of pathologic classification?

Does he believe in the existence of anything like "muscular equilibrium," and if so, does he believe that it is peculiar to the eye muscles?

Does he think that the human being comes into the world with the eye muscles tuned to a definite equilibrium, and that when there is a failure to "balance" they can be "equilibrated" into tune?

Does he believe asthenopia is a local disease, curable by "refracting" the eyes and equilibrating the muscles?

These questions are asked because unless he regards the condition of the eye muscles, their length, strength and innervation, as having a very great importance, a predominating importance, in the production of not only eye strain but disease, his reference to the American Ophthalmologic Society is apparently motiveless. The members of the Society can speak for themselves, but there are many, not members, who think that too much time at meetings, and too much space in literature has lately been occupied with what might be termed pseudo-scientific essays; and so termed because, while presented in a scientific manner, they failed in the accurate statement of premises. There are many facts in regard to the action of the external eye muscles, separately and in binocular vision, also much that is known about the shape and size of retinal images; many experiments in physiologic optics and a very great amount of clinic history, that must be explained before the doctrine as to the great importance of the muscles in causing disease, or even symptoms of eye-strain, can be accepted.

Without emulating the ardor with which the future, twenty years ahead is predicted for us, it may be altogether too conservative to believe that a dogmatism which ignores the principles of evolution, overrides comparative anatomy, suppresses a long chain of experimental results in physiologic optics, and enunciates a pathologic theory, a new nomenclature, and a wildly brilliant system of therapeutics, all in one decade, may be "out of sight" twenty years hence. Meanwhile "conservatives" who see in eye-strain and muscular incoördinations symptoms having their origin in widely differing conditions, will treat the patient instead of the symptom, with quite as good results as their brethren who equilibrate according to the readings of the phorometer.

"HALLER."

The Standing of American Ophthalmology.

MILWAUKEE, March, 23, 1896.

To the Editor: Exception may well be taken to the arrangement of ophthalmic surgeons generally and of ophthalmology in the rather rambling editorial published in the issue of March 21, which is intended to impress the reader with the idea that American ophthalmic authors, particularly those of the American Ophthalmological Society are "ashamed of what they should be proud of."

The innuendoes of this editorial are certainly distasteful to the majority of the 267 members of the Section on Ophthalmology of the AMERICAN MEDICAL ASSOCIATION, and may be particularly so to a considerable number of those who are also members of the American Ophthalmological Society. Perhaps there may be cause to criticize the 1895 Transactions of the latter. I am, however, unwilling that such a stricture should be passed upon American Ophthalmology and upon that large and growing (!) class of practitioners who are particularly interested in this branch of medicine.

This is perhaps the only instance coming to my notice where ophthalmic authors have been criticized for what they have *not* written. Indeed, the large number of technical articles, especially on refraction and allied subjects, appearing in general journals, has been a cause of remark by brother practitioners who are not specially interested and who will not read such. "Eye-strain" has been harped upon *ad nauseam* in this country and ophthalmologists have something to do besides fitting patients with glasses and writing glowing *post hoc* accounts of their wonderful effects.

However, the ophthalmic division of our profession points with pride to the original work of American authors in the line of refraction and muscular anomalies. The records of even the last year show that distinct advances in other branches of medicine have been reported by authors whose professional work and the most of whose writings are of a special nature.

Ophthalmology is still an example for emulation, particularly as it is represented by the Section on Ophthalmology of the AMERICAN MEDICAL ASSOCIATION. I need but refer to the work done by our members and published in our journal since the time that the balance of the AMERICAN MEDICAL ASSOCIATION followed in the lead of the Section on Ophthalmology, when the Section was so ably reorganized in 1891 by the then chairman, Dr. Leartus Connor, of Detroit, and his associates. The methods of this Section were followed by the others and the pace is still set.

The employment of the columns of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for ill-considered editorials which reflect upon a part of its members and tend to promote discord, is to be sincerely disparaged.

H. V. WÜRDEMANN.

Abdominal Section for Lead Colic.

DAYTON, OHIO, March 18, 1896.

To the Editor: In your January issues which I have just seen, Prof. John B. Murphy reports a case of abdominal section for dynamic intestinal obstruction from lead poisoning and considers it the only one published. I also consider it the only one and am prompted therefore to report the following case of my own: A painter 20 years of age, had had no passage from the bowels for five days, according to one report ten days. Abdomen retracted and soft, but tender on one spot near the umbilicus; considerable pain; vomiting several days, so-called stercoraceous at last. He had had very copious irrigations, oil enemata, moderate salines and six drops of croton oil which probably was vomited. His condition was excellent, pulse slow and regular, temperature 99.6 degrees. Behavior peevish, so that operation was deferred as long as practicable. In the interim a third consultant was called who indepen-

dently advised an operation. Abdominal section showed nothing, but near the umbilicus a sudden narrowing of the small intestine to the size of a lead pencil, which narrowing continued throughout most of the distal portion of the small gut. The narrowing disappeared when the intestinal contents were "stripped" into it and the slightly swollen and bluish bowel above the obstruction now took on a healthier appearance. More stripping was done and the abdomen closed. He never vomited after the operation and became hungry after the first day; considerable flatus through the rectal tube but no tympanites; occasionally slight tormina in flanks; salines end of second day gave several movements. Further convalescence disturbed only by a neural abscess from a bleeding stitch hole.

J. C. REEVE, JR., M.D.

Satisfied, but Sore.

FREDONIA, N. Y., March 19, 1896.

To the Editor:—Yours to hand soliciting my subscription to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Not until the ASSOCIATION rids herself of the charge of bigotry and infallibility, and treats some of her New York members, who happen to think differently from her, with more courtesy and consideration, do I aspire to be a member or propose to subscribe to her JOURNAL. Besides the *Medical Record* and the *Buffalo Medical and Surgical Journal* fill this niche of journalism very nicely. I have, however, for you personally, my dear sir, the highest consideration and esteem.

Very truly yours. NELSON G. RICHMOND.

BOOK NOTICES.

Physicians and Surgeons of America. (Illustrated.) A Collection of Biographical Sketches of the Regular Medical Profession, edited and compiled by IRVING A. WATSON, A.M., M.D., Concord, N. H., Republican Press Association, 1896.

The published works in this country devoted exclusively to medical biography are few, chiefly "American Medical Biography," by James Thacher, 1828; another volume with the same title by Stephen W. Williams, 1845; "Lives of Eminent American Physicians and Surgeons," by S. D. Gross, 1861; "The Physicians and Surgeons of the United States," by Wm. B. Atkinson, 1878; "Biography of Eminent American Physicians and Surgeons," by R. French Stone, 1894, and lastly the work now before us. This is a handsome volume of 843 double column pages containing notices and portraits of 1,218 physicians and surgeons, twenty of whom are women. According to the preface: "All classes of reputable regular practitioners belonging to accredited medical societies have been recognized from the ablest and most eminent to the unassuming country physician, who tirelessly laboring day and night for the alleviation of human suffering, is as worthy of a record as are many who have become more distinguished." We notice, however, the absence of many whom we regard as at the head of the profession in their locality, the explanation of which is no doubt to be found in the absolute refusal of many physicians to have their biography published while living. As a matter of fact an obituary flavor does attach to all these sketches, because we are accustomed to such reading only after the demise of the individual; but the excellent portraits accompanying the text of Dr. Watson's book remove the funereal flavor and recall to us that our many friends here presented are yet among the active laborers in the work of the profession. The fact that the compiler has been for so many years the Secretary of the American Public Health Association explains why the work contains notices of so many of the men who have devoted their attention specially to sanitary subjects. There is no alphabetic or other systematic arrangement of the biographic notices, for among the first portraits

which we personally recognize are those of Surgeon-General Sternberg, Orpheus Everts, A. L. Gihon, L. A. Sayre, N. S. Davis, T. Grange Simons, S. E. Chaillé, etc. There is, however, at the end an alphabetical index for convenience of reference and also an index by States and localities. New York State has the largest representation, 223, of whom 99 belong to New York city and 31 to Brooklyn. Pennsylvania has 87, of whom 30 belong to Philadelphia; Massachusetts 74, 27 of whom are in Boston, and Illinois has 65, nearly half of whom, 31, are in Chicago. Mexico is represented by 5 medical men; Utah, Arizona and Idaho each by 2, and New Mexico and Delaware each by only 1 medical man.

Clinical Lectures of Abdominal Surgery and Other Subjects. By CHARLES T. PARKES, A.M., M.D., late Professor of Surgery, Rush Medical College, Surgeon to the Presbyterian Hospital, Surgeon in Charge of St. Joseph's Hospital, Surgeon in Chief of Augustana Hospital, Consulting Surgeon Hospital for Women and Children, etc. Edited by Dr. A. J. Ochsner. Cl., 8vo, gilt top, pp. 477. Chicago: The W. T. Keener Co. 1896.

The editing of a posthumous book is attended with many disadvantages, one of the most serious of which is the fact that owing to the rapid changes and new discoveries, our pathology is constantly being revised, and a man's remarks when kept five years may be of a character quite out of touch with the current literature. On the other hand, should the editor interpolate, alter or much change, the work then becomes a joint production. Under the circumstances, Dr. Ochsner has chosen, we think wisely, to preserve as much as possible of the language of the author. The many friends of the lamented Parkes will notice with pleasure that his now classic paper on gunshot wounds of the small intestines, read before the AMERICAN MEDICAL ASSOCIATION in May, 1884 (see JOURNAL 1884), is reprinted here for permanent preservation. But the reputation of Professor Parkes as a surgeon, a lecturer and teacher will not depend upon anything incorporated in this volume. It is rather in the hearts of the alumni of the great college in which he taught, that his memory will be cherished and kept green. His stalwart form, his keen yet kindly eye, his manual dexterity, his quickness, his minute knowledge of anatomy and his overrunning good nature are the characteristics by which those who heard him lecture in the clinic amphitheater made famous by Brainerd and Gunn before him, and to whom he was no unworthy successor, will best remember him. He died when he had just reached the goal for which he had striven for so many years, but the steps by which he reached it are demonstrated in the volume under consideration.

Random Thoughts. By JOHN MULLIN BATTEN, B. E., M.D., etc. Cl. pp. 319. Pittsburg: Published for the author 1896.

This book is the revised and enlarged edition of a previously published book entitled "Two Years in the United States Navy" and which now appears under a new title. The author's description of his early childhood, his schoolboy days and his experiences while teaching school is told quaintly, and with such entire candor as to disarm criticism. His account of the stirring scenes of the Civil War, which came under his own observation are extremely interesting. There are essays on various subjects beside the personal narrative. One in particular on "Matrimonial Alliances" deserves to be widely read and its teachings acted upon by the matrimonially inclined.

A Pictorial Atlas of Skin Diseases and Syphilitic Affections in Photo-Lithochromes from models in the Museum of the Saint Louis Hospital, Paris, with explanatory wood-cuts and text, by Ernest Besnier, A. Fournier, Tenneson, Hallopeau, Du Castel, Henri Feulard and Leon Jacquet. Edited and annotated by J. J. PRINGLE, M.B., F.R.C.P. London. To be published in twelve parts. Part 2. Price, \$3 a part. The Rebman Publishing Co. Philadelphia: W. B. Saunders. 1895. Sold by subscription. W. T. Keener, Chicago agent.

We gave our favorable opinion of this great work on the appearance of the first part, and the execution of this second

part is quite equal to the first. Every physician can not go to Paris to inspect the original models with the assistance of a competent guide and instructor, but every one can obtain this representation in colors exactly conforming to the Parisian model and the explanatory text written by those most familiar with the original. This part contains articles and plates illustrating lupus erythematosus of the face, hypertrophic rosacea of the forehead, circinate syphilitic lesions of the skin (confluent and cockade shaped) and xanthoma planum et tuberosum in a glycosuric, icteric and obese subject. These plates are accurately colored, and the models of which they are copies were made by Baretta from life.

Electricity in Electro-Therapeutics. By EDWIN J. HOUSTON, PH.D., and A. E. KENNELLY, Sc.D. Cl., pp. 402. New York: The W. J. Johnston Company. 1896.

This work is written, as we are assured, in response to a growing demand which exists for reliable information respecting the physics of electro-therapeutics. An examination of the book justifies the belief that the authors have not only given some very useful and necessary information, but have made the technicalities of the subject easy to comprehend. The illustrations are numerous and excellent.

Atlas of Traumatic Fractures and Luxations. With a brief treatise by H. HELFERICH, M.D., with one hundred and sixty-six illustrations after original drawings by Dr. Joseph Trupp. Cl. pp. 142. New York: Wm. Wood & Company. 1896.

This atlas and treatise constitute a work of practical utility for students, from the well-known Professor Helferich, of the University of Greifswald, who for many years was Thiersch's assistant. The illustrations are generally good and are mostly from recently prepared specimens. They will repay careful study.

A Manual of Jurisprudence and Toxicology. By HENRY C. CHAPMAN, M.D. Second edition, revised, with 55 illustrations and three colored plates. Cl. pp. 254. Price \$1.50 net. Philadelphia: W. B. Saunders. 1896. [W. T. Keener, Chicago agent].

The first edition of this manual was published late in 1892, and its popularity is attested by its rapid sale. It is divided into two parts: the first, medical jurisprudence containing fourteen chapters and the second, two chapters on toxicology.

It is an excellent manual in which an accurate epitome is given of the existing knowledge on the subject. It is fairly illustrated and well printed on good paper.

Voice Building and Tone Placing. Showing a new method of relieving injured vocal cords by tone exercises. By H. HOLBROOK CURTIS, Ph.B., M.D. Cl. pp. 215. New York: D. Appleton and Company. 1896.

"When music, heavenly maid, was young," we doubt that she wasted many moments in studying the anatomy of the vocal cords or the physiology of articulate language. The modern votaries of music require a knowledge of anatomy of the organs concerned in voice production, their function and the means of maintenance at their highest point of perfection. Those interested in elocution as well as music, will find this volume both instructive and entertaining. The chapter on the eidophone is particularly interesting.

Iron in the Different Organs in Anemia. Stühlen's microchemic study of the amount of iron deposited in the various organs, shows that the chief seat of this deposit is the liver and spleen in pernicious anemia. In cases induced by an excessive loss of blood or any secretion, the amount of iron in the organism is far below normal, and the liver and spleen are here again pre-eminent. In severe and pernicious anemia iron is also deposited in the kidneys. It extended into the urethral canals, but the glomeruli never showed a trace of it. In the liver it extended over the peripheral portions of the lobes, and in the spleen it was found mainly in the pulp. *Centralblatt f. Phys.*, February 22.

PUBLIC HEALTH.

Not to Give Cigarettes to Minors.—A law was passed in New Hampshire in 1895 which provides that if any person other than the minor's parent or guardian shall give or deliver any cigarette, snuff or tobacco in any of its forms to any minor under 18 years of age, he shall be fined not more than fifty dollars for each offense.

Amendment of Missouri Pharmacy Law.—A new section was added to the Missouri pharmacy law in 1895 to be known as Section 4625 *a*, which provides that the board of pharmacy shall, upon application, and at such time and place and in such manner as they may determine, examine every person who shall desire to conduct the business of selling at retail, compounding or dispensing drugs, medicines or chemicals for medicinal use, or to compound and dispense physicians' prescriptions as pharmacists; and if a majority of said board shall be satisfied that said person is competent and fully qualified to conduct said business, they shall enter the name of such person as a registered pharmacist in the book provided for that purpose: Provided, that the board of pharmacy, in conducting examinations under the provisions of this section, shall not be permitted to inquire into the source of information of any applicant, but shall subject all applicants to the same examination, and require of all the same degree of efficiency.

Missouri Embalming Law.—A law was passed in Missouri in 1895 establishing a State board of embalming, to consist of five members to be appointed by the governor. It is to prescribe a standard of proficiency as to the qualifications and fitness of those engaged and who may engage in the practice of embalming and the care and disposition of dead human bodies within that State. Applicants for a license must be of good moral character and, upon due examination, satisfy the board that they are possessed of a knowledge of the venous and arterial systems, the location of heart, lungs, stomach, bladder, womb and other organs in the human body; the location of abdominal, pleural and thoracic cavities; the location of the carotid, brachial, radial, ulnar, femoral and tibial arteries; a knowledge of the science of embalming and the care and disposition of the dead, and have a reasonable knowledge of sanitation and the disinfection of bodies of deceased persons, and the apartment, clothing and bedding, in case of death from infectious or contagious diseases. Licenses are to be registered in the Probate judge's office and displayed in the practitioner's office. Renewal of registration with the secretary of the board must be made annually.

New York Opticians Seek Protective Legislation.—Legislation that is protective of the eyes of the public, and at the same time of the interests of the craft of the opticians, is being agitated in New York State, in the form of a bill introduced by the Public Health Committee of the Assembly. Under this bill, a society, called the "Optical Society" of the State of New York, is to be incorporated, and has for its avowed object the improving and regulating the practice of dispensing and refracting opticians in this State. The bill makes it the duty of the society to nominate on or before the third Tuesday in May of each year six persons, from whom the Board of Regents of the University of the State of New York shall appoint three on or before the first day of July of each year, who shall compose the State Board of Examiners of the Optical Society of the State of New York. It shall be the duty of the Board of Examiners to examine all persons applying for certificates to practice as dispensing or refracting opticians of the State of New York, and to keep a record of certified opticians. It shall be unlawful for any person, on and after the first day of August, 1896, to practice as an optician by executing ophthalmic prescriptions for lenses or adapting glasses to the sight, unless he shall have been granted a certificate.

To Teach how Diseases are Spread.—A law was passed in Michigan in 1895 requiring that there shall be taught in every year in every public school in that State the principal modes by which each of the dangerous communicable diseases are spread, and the best methods for the restriction and prevention of each such disease. The State Board of Health is to annually send to the public school teachers and superintendents throughout the State printed data and statements which shall enable them to comply with this law. School boards are required to direct such superintendents and teachers to give oral and blackboard instruction, using the data and statements supplied by the State Board of Health. Neglect or refusal on the part of any superintendent or teacher to comply with the provisions of this law shall be considered a sufficient cause for dismissal from the school by the school board. Any school board willfully neglecting or refusing to comply with the provisions of this act shall be subject to fine the same as for neglect of any other duty pertaining to their office. This law applies to all public schools in the State, including schools in cities or villages, whether incorporated under special charter or under the general laws.

How Sanity is Determined in Michigan.—Whenever any person, upon application to any probate court in Michigan for his admission into any asylum, home or retreat, for the care of the insane, shall have been adjudged by such court insane, and shall have been released from or shall not have been received into any such asylum, home or retreat, application, it was enacted in that State in 1895, may be made to such court for a finding and order, declaring such person restored to soundness of mind. The court is then to fix a time for the hearing of such application, and in case the application is made by the person adjudged insane shall cause notice to be given to the person who applied for the order of admission, if he be found in that county, and may cause such further notice to be given as it deems proper. If upon the hearing of the application, the court, from the testimony given, shall find the person restored to soundness of mind, an order shall be entered in the journal of the court declaring him sane: provided, however, that the testimony of at least two reputable physicians establishing the sanity of the person shall be required before the finding of the court and entry of such order.

New Jersey Health Laws.—Several important acts were passed in New Jersey in 1895 relative to the preservation of the public health. Boards of health in cities of the first class are authorized to grant and regulate permits incident to health matters and fix fees to be paid therefor. They are also empowered to pass, alter and repeal ordinances relating to the public health of such cities, and fix the amount of fines and penalties for the violation thereof, except in counties where there are established county boards of health and vital statistics the ordinances of neither the city or county board are operative until the respective boards shall agree thereto and by ordinance enact and define their separate and respective jurisdictions within the limits of such city. Without this last restriction, much the same authority is given to boards of health in cities containing a population of over one hundred thousand. Where the board of health of any city has established or shall establish a plant for the production of diphtheria anti-toxin serum, and shall be engaged in the production thereof, it shall have power to sell the surplus to any municipality or person desiring to purchase it. The common council or other legislative body of any city of the second class may, whenever it is by it deemed necessary purchase land in said city and erect a building or buildings thereon to be used for a hospital for contagious diseases, the plans being first approved by the mayor and the local board of health. After the building or buildings shall be completed, the same shall be in charge of and under the direction of the board of health. The State board of health or any offi-

cer acting for it, having reason to believe that any milk has been contaminated by the emanations, exhalations or discharges of any person sick with communicable disease may prohibit the transportation or sale of such milk. The manufacture and sale of adulterated candy is prohibited. Boards of health in cities of the first class may condemn and prohibit the sale or use of impure ice or ice cut from polluted streams. Provision is also made to prevent deception in the sale of cakes and biscuit, in the State.

New York City's "House Boat" for the Homeless begins Operation. Employment, food, a bath and clean clothing all in one breath, so to speak, are provided by the new experiment now on trial at the New York City Floating Lodging-house, also called "The City's House-Boat." The following is an explanation, taken from a New York newspaper, of the first day's plan of operations: "A floating lodging-house does not necessarily mean a lodging-house for floaters, though in political seasons it might take that shape. Such a house has been established at Twenty-sixth street and East river, and it looks as if it would prove to be a success. There are baths and beds for quite a company; the baths are compulsory conditions on the beds. Every man who sleeps there has the use of a gown and a pair of slippers and he has two meals. In return for these advantages he must do three hours' work on the day of the opening, the thing that needed most to be done was the clearing of snow from the streets and walks, and the candidates were set to work on the grounds of Bellevue Hospital. They shoveled and swept thoroughly and with a good spirit. The baths were not accepted so eagerly. Some of them shrunk and tried to dodge, but the keepers were inexorable and bathe they did. A few to their own great astonishment, found that they liked it, and they may have formed a habit that will either kill or improve them in a few years. Those who have made a study of tramps hope it will do one thing or the other.

"The apparent success of this enterprise is a little surprising, for heretofore the usual wanderer has objected to making any return for the favors he receives from lodging-house keepers and other such public agents. Perhaps we must look for the solution of this mystery in the fact that the men are employed together, and are therefore able to enjoy each other's society while they toil. There is an infection of purpose and enthusiasm in numbers. Charity is no longer founded on sentiment. We realize from the reports of experts in crime and pauperism that most of the good deeds done by soft hearted persons have tended only to perpetuate laziness and false pretense, and it is becoming harder and harder for the drunken, vicious, useless vagrant to gain the ear of sympathy. There is, however, a need of places like the floating lodging-house, where the worthy poor can escape from the severities of the weather, allay the gripe in an empty stomach, renew self respect in a bath tub, and possibly secure employment that will put them on their feet again."

New Jersey Pharmacy Law Changes.—The pharmacy law of New Jersey was amended in 1895 and thereby changed in the following important particulars. Meetings of the board of pharmacy of the State are to be held on the third Thursday of January, April, July and October, in the city of Trenton, and at such other places and dates as may be required. The board is to grant certificates of registration to all persons whom it shall judge, on examination, to be properly qualified to practice pharmacy. It is given the additional power to suspend and revoke the registration of any person addicted to chronic and persistent inebriety, or of any person convicted of a crime involving moral turpitude. Applicants for registration must now be not less than 21 years of age, and pay to the secretary of the board a fee of \$10, those failing to pass examination being given the right to try a second time at any time within one year thereafter. It is also now provided that the board of pharmacy shall grant an assistant's certificate to any person not less than

18 years of age, who shall have had three years' practical experience in pharmacies where prescriptions have been usually compounded, and shall have passed a satisfactory examination before said board of pharmacy: which certificate shall entitle such person to all the privileges of a registered pharmacist during the temporary absence of his employer, and shall not entitle such assistant to engage in business on his own account or as manager to conduct a pharmacy. Every person applying for an assistant's certificate shall pay to the secretary of the board of pharmacy a fee of \$5 before examination, and in case of failure to pass a satisfactory examination the applicant shall be granted a second examination without the payment of another fee at any time within one year from his first examination. Every registered pharmacist and every registered assistant who desires to continue the practice of his profession shall once in three years during the time he shall continue such practice, on such date as the board of pharmacy shall prescribe, pay to the secretary of the board a registration renewal fee of fifty cents, in return for which he shall receive a renewal of his registration. A penalty is prescribed for failure to register and for dispensing adulterated drugs, as well as for procuring or attempting to procure registration fraudulently or by false representation. The exception made in favor of the making or vending of patent or proprietary medicines, and of the sale of simple domestic remedies by retail dealers in rural districts, is limited to such as are non-poisonous and it is no longer required that the retail dealer in rural districts be one-half mile or more remote from a registered pharmacist.

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Alabama: Mobile, March 12 to 14, 2 cases.
Arkansas: Jacksonport, March 17, 4 cases.
Florida: Pensacola, March 18, 1 case.
Louisiana: New Orleans, March 7 to 14, 116 cases, 10 deaths;
Shreveport, February 26 to March 20, 16 cases, 1 death.
Michigan: Bay City, Detroit, Imlay Township, Ionia,
Marine City, Saginaw, March 7 to 14, smallpox reported.
Tennessee: Memphis, March 21, 2 cases.
Texas: Center, March 13, 1 case; Orange, March 18, 1 case.

SMALLPOX—FOREIGN.

Bombay, February 11 to 18, 27 deaths.
Brussels, February 22 to 29, 1 death.
Cairo, February 5 to 18, 5 deaths.
Cardiff, March 1 to 7, 2 cases.
Constantinople, October 1 to 31, 5 deaths.
Genoa, March 1 to 7, 2 cases.
London, February 22 to March 7, 2 deaths.
Madras, February 8 to 14, 1 death.
Moscow, February 15 to 22, 1 death.
Prague, February 22 to 29, 4 cases.
Tuxpan, February 22 to 29, 1 death.
Warsaw, February 8 to 22, 6 deaths.

CHOLERA—FOREIGN.

Calcutta, February 1 to 8, 66 deaths.

YELLOW FEVER—FOREIGN.

Santiago de Cuba, March 1 to 7, 6 deaths.

ASSOCIATION NEWS.

Provisional Program for the Atlanta Meeting of the Ophthalmological Section of the AMERICAN MEDICAL ASSOCIATION.
LUCIEN HOWE, Chairman, FRANK ALLPORT, Secretary.

Address of Chairman, LUCIEN HOWE.

Report of Special Committee on Detachment of the Retina, its Etiology and Treatment, R. E. RANDOLPH, Chairman.
Histologic Changes in Retinal Detachment.

Papers from F. C. HOTZ, E. E. HOLT, F. E. WEEKS, T. E. MURRELL, subjects unannounced.

JOHN F. FULTON, Operative Treatment of Detached Retina.

L. F. LOVE, Report of a Case of Detached Retina Occurring in Chronic Bright's Disease.

W. T. MONTGOMERY, Electrolysis in the Treatment of Detached Retina.

E. OLIVER BELT, Consanguineous Marriages as a Cause of Retinitis Pigmentosa.

March 15, 1896.

SOCIETY PROCEEDINGS

Chicago Ophthalmological and Otological Society.

Regular Meeting held at the Chicago Athletic Association, Feb. 11, 1896.

DR. GRADLE in the Chair.

There were twenty-two members in attendance. The minutes of the last meeting were read and approved.

The Secretary read the application of Dr. J. B. LORING, which was referred to the Committee on Membership.

DR. GRADLE read a paper entitled

THE EFFICIENCY OF SALICYLATES IN THERAPEUTIC PRACTICE.

The speaker explained that salicylates have been used in ophthalmic practice and recommended in the books for nearly twenty years, but that very few authors state definitely what and how much can be expected of the drug in different diseases. In the mild forms of episcleritis the salicylate of sodium has a prompt effect in checking the disease. In corneal diseases he has found it useless except in one form, keratitis, presumably dependent upon rheumatism or gout. This keratitis is characterized by deep striations or discrete spots of infiltration in the cornea, with a more or less diffuse haze. It has an indefinite course, but yields within a few days to the action of salicylate of sodium. In iritis the speaker has never observed specific effect. In eight instances patients with rheumatic manifestations and iritis were benefited as far as the rheumatism was concerned, but the salicylic acid did not prevent the iritis from taking its usual course. He claims, however, that this drug will often mitigate the pain and in some instances apparently shorten the disease, but that this effect can not be predicted. It requires doses of at least one gram, repeated four or six times a day, in order to obtain the benefit of salicylates, and more if the patient can stand it. In cyclitis the most striking results were seen. It has no effect upon an acute cyclitis, but when the disease has passed the acute stage and then has an indefinite duration, or exacerbations and relapses, a very prompt checking effect was found in the majority of instances. This pertained to cyclitis following retinal detachment, cyclitis of traumatic origin, and in one instance a sympathetic form of disease. Sometimes a marked benefit was found in twenty-four to forty-eight hours. In no other disease of the eye could any decisive results be obtained by the use of salicylate of sodium.

DISCUSSION.

DR. HOLMES had used salicylates only for the relief of pain. For this purpose he had found them of great help, but had not had very satisfactory results from salicylates as a specific.

DR. COLBURN had used salicylates at times, but finds that antipyrin and similar analgesics accomplish the same results, and as they were less irritating to the patient's stomach he considered them better. He used all these drugs for the relief of pain only, and not as specifics.

DR. HOTZ had first used the salicylates systematically in 1878 and reported his results in the *Chicago Medical Journal and Examiner* in 1879, about the time that Chisholm made his report. He disagreed with the former speakers in regard to the value of the salicylates as a specific. In cases of rheumatic iritis the relief from pain and other symptoms was very marked, following the administration of the salicylates in large doses. Referring to the benefits Dr. Gradle had derived from them in cases of cyclitis, but not in iritis, he considered that all severe cases of iritis were complicated with cyclitis, and that Dr. Gradle's experience was only proof of the value of salicylates in iritis. He generally gave the salicylate of sodium in 5 grain doses, repeated at very short intervals, instead of 15 grain doses every two hours or so.

DR. COLEMAN's experience corresponded with Dr. Gradle's as far as iritis is concerned. He had found the drug of but

little value, although he had used 15 grain doses very persistently. He now uses 1-10 grain doses of calomel, repeated every hour until relief is experienced. A recent case of herpes zoster ophthalmicus, which had suffered greatly from severe pain for ten days, was relieved by salicylate of soda, when all other drugs had failed except morphin.

DR. HALE asked if Dr. Gradle had ever used oil of wintergreen instead of salicylates. He had found the oil of wintergreen just as efficacious, and it did not disturb the patient's stomach nearly as much as the salicylate of soda.

DR. PIERCE also spoke of the use of wintergreen in his practice as being very satisfactory. He considered it important to get a reliable preparation of the drug, and he uses Merck's oil of wintergreen entirely.

DR. WÜRDEMANN had but little use for the salicylates. In iritis he had always used mercury with satisfactory results.

DR. HAWLEY used to use salicylate of soda, but found it very irritating. He now prefers salicin and gives very large doses, 20 grains every hour, and sometimes as high as 30 grains every hour. He finds salicin is less irritating, and has never had any unpleasant effects from the use of such large doses.

DR. OAKS uses the salicylic acid prepared from the oil of wintergreen, and not the one used synthetically. He finds the results are better and the preparation less irritating than the synthetic form.

DR. GRADLE (in closing) said that he prefers the salicylate of soda in the solid form: that in the form of 5 grain tablets it was less irritating than in solution. He finds it is absolutely useless to use doses smaller than 15 grains, repeated every two or three hours.

DR. COLBURN reported the case of a boy of 15, who six months before the doctor saw him, noticed a small cyst the size of a pea between the cornea and the inner canthus which rapidly grew larger. When seen by the doctor the cyst had spread until it occupied part of the cornea, and it could be plainly seen that the cyst had invaded the corneal walls, and that both the front and back walls of the cyst were formed by corneal tissue, the cornea still remaining transparent. The tension of the cyst was about that of the eye. Photographs of the cyst were shown. The conjunctiva was opened over the cyst, and it was found the outer wall was composed of sclerotic and corneal tissue. A small puncture made through this wall allowed quite a little thin, transparent fluid to escape, and a larger incision showed the inner wall of the cyst to be also composed of scleral and corneal tissue. Nothing was found in the cyst with the exception of this clear fluid. It healed rapidly and the two walls united with obliteration of the sac.

In looking up the literature Dr. Colburn was unable to find any reference to similar cysts. He finds, however, two cases, in one of which a cysticercus was found in the cyst, and in the other case a piece of steel.

As far as the etiology of this case is concerned, the only previous history was an injury to the eye in childhood from a dog bite, the scar of which is plainly visible.

DR. WÜRDEMANN referred to one case of echinococcus cyst of the sclera, which will be reported in the new System of Ophthalmology of Norris and Oliver.

DR. COLEMAN spoke of the question of finding the axis for weak cylinders, and referred to the method recommended by Price about a year ago of using quite strong cylinders in determining this axis, the cylinder used being too strong to give good vision, but slight deviations from the proper axis making the vision still worse. In this way he had succeeded in finding the axis for the weak cylinder, which he could not do in any other manner.

On motion, the Society adjourned.

C. P. PINCKARD, Secretary.

103 State Street.

SOCIETY NEWS.

American Academy of Medicine. Preliminary "press notice" of the twenty-first annual session at Atlanta, Ga.: The twenty-first annual session of the American Academy of Medicine will be held at the Hotel Aragon, Atlanta, Ga., Saturday, May 2, and Monday, May 4, 1896. The proprietors of the Aragon have made special rates for those who attend the meeting; it is expected that the concession for one and one-third fare for the round trip granted to the AMERICAN MEDICAL ASSOCIATION will be available in time for those who desire to attend the opening session; a pleasant excursion can be arranged to start from Philadelphia and visit Asheville, N. C., the "Land of the Sky," and Chattanooga, *en route* to Atlanta, if a sufficient number club together for that purpose; or special Pullman cars can be chartered for the exclusive use of those who attend the meeting for the direct route to Atlanta from any rendezvous selected. The Secretary invites correspondence on any of these topics, and also from those who desire a copy of the completed program, when it is issued; full information will be promptly given on application.

Provisional Program: The Academy will meet in executive session with closed doors on Saturday, May 2, at 10 A. M. The open session for the reading of papers will begin about 11 A. M. The reunion session and annual dinner will be held on Saturday evening. An executive session will be held on Monday morning, after which the special discussion on "Methods of Medical Education" will be the order of the day. The Association of American Medical Colleges, and the Confederation of the State Boards of Medical Examiners and Licensers, have accepted the invitation of the Council and will participate in this discussion. The time-table for the day and the time for adjournment will be determined by the circumstances.

Papers promised: (Note. No attempt is made to arrange the papers in the order in which they are to be read.) 1. "Laboratories and Hospital work," the President's Address, Henry M. Hurd, Baltimore, Md. 2. "Colonies for Epileptics," Frederick Peterson, New York City. 3. "Insanity in the South," J. T. Searcy, Tuscaloosa, Ala. 4. "Tuberculosis in Public Institutions," J. W. Babcock, Columbia, S. C. 5. "Vivisection," George M. Gould, Philadelphia. 6. Subject not yet given. Woods Hutchinson, Iowa City, Iowa. 7. "The Confusion of Pharmacy Relating to the Theory and Practice of Medicine," Elmer Lee, Chicago. 8. "A National Board to License for the Practice of Medicine," Henry Leffmann, Philadelphia. 9. Report of the Committee to Abstract the Laws Regulating the Practice of Medicine and to Suggest a Model Law, Perry H. Millard, Chairman, St. Paul, Minn. 10. "Homicide," Paul Bartholow, Philadelphia. 11. "The Sociologic and Scientific Attitude of the Medical Profession," W. J. K. Kline, Greensburg, Pa. 12. "A Study of Some of the Distinguishing Features of the Homo Medicus," Charles McIntire, Easton, Pa.

Discussion on "Methods of Medical Teaching": This discussion will be opened by a series of ten-minute papers, and in the discussion to follow, each speaker will be limited to five minutes. The papers are as follows: 13. "The Preparatory Mental Discipline for the Medical Student," F. H. Gerrish, Portland, Me. 14. "The Lecture and its Uses," Charles B. Penrose, Philadelphia. 15. "Text-book Recitation and its Advantages," De Lancey Rochester, Buffalo. 16. "Laboratory Methods," V. C. Vaughan, Ann Arbor, Mich. 17. "Clinical Teaching for Graduates in Diseases of Children," J. Madison Taylor, Philadelphia. 18. "The Seminary Method," Bayard Holmes, Chicago. 19. "Examinations," E. L. Holmes, Chicago. 20. "Students' Medical Societies," Roswell Park, Buffalo. 21. "State Examination," J. McPherson Scott (of the Maryland Board of Examiners), Hagerstown, Md. 22.

"The Best Method to Teach Anatomy." John B. Roberts, Philadelphia. 23. "The Best Method to Teach Physiology." Charles D. Smith, Portland, Me. 24. "The Best Method to Teach Practice." J. C. Wilson, Philadelphia. 25. "The Best Method to Teach Surgery." J. S. Wight, Brooklyn. 26. "The Best Method to Teach Obstetrics." J. C. Edgar, New York City. 27. "The Best Method to Teach State Medicine." George H. Rohé, Catonsville, Md. Correspondence is pending about some additional papers; if any more are promised, the titles will appear in the completed program.

CHARLES MCINTIRE, Secretary.
Easton, Pa.

NECROLOGY.

DORRANCE K. MANDEVILLE, M.D., who was formerly a surgeon in the United States Marine-Hospital Service, died at Brooklyn on the 9th inst., aged 68 years. At the time of his connection with the Marine-Hospital Service he was a resident of Mobile, Ala., whence he removed in 1866 to reside at Clinton, N. Y., he having been a graduate in arts at Hamilton College in 1849. His medical degree was obtained from the College of Physicians and Surgeons, New York. He removed from Clinton to Brooklyn in 1876. He was an ex-interne of Bellevue Hospital.

NELSON FANNING, M.D., died at his home in Catskill, N. Y., February 27. He was one of the oldest physicians in the United States. He was graduated from the now extinct Berkshire Medical College in 1830, having been in active practice until within a few days of his 88th birthday. He had been continuously a medical practitioner for sixty-five years, and was the dean of the faculty of Greene County. In the war of the rebellion he served nearly two years as surgeon of the 134th New York Volunteers.

JOHN S. DANIELS, M.D., a well-known surgeon in New Hampshire, died March 6, at Rochester, N. H. He was born in Barrington, that State, and educated at the Long Island Medical College in the class of 1875.

GEORGE BADGER COGSWELL, M.D., of North Easton, Mass., died March 6, in the sixty-third year of his age. He was a native of Bradford, Mass., educated at Wilmington Academy and Dartmouth College, was A. M. of that institution in 1850, and M.D. of its medical department in 1857.

JOHN HOWARD RIPLEY, M.D., formerly President of the Faculty of the St. Francis Hospital, New York city, was the subject of the following tribute of respect by his fellows of the Medical Board of that institution:

WHEREAS, It becomes our painful duty to announce the death of Dr. John Howard Ripley, attending physician to St. Francis Hospital, and late President of its Medical Board; therefore, be it

Resolved, That the Medical Board desires to place on record its due appreciation of his long and valuable services to this institution, faithfully and cheerfully rendered for nearly a quarter of a century; and be it

Resolved, That from his first connection with this hospital he was an ever-willing servant for its best interests, an ardent promoter of its highest aims and an active participant in all its charitable benefactions; and be it

Resolved, That the remembrance of his manly disposition, his frank manner, his energetic spirit and scholarly attainments will ever serve as a cherished lesson for the well ordered life of a dutiful worker, an indefatigable investigator and a model physician.

THOMAS C. BRADFORD, M.D., died March 13, after an illness of two weeks. Dr. Bradford was born in Cincinnati in 1835 and he graduated from the Bellevue Hospital Medical College, New York, in 1864, since which time he has practiced his profession in Cincinnati.

J. W. IRELAND, M.D., died on the evening of the 15th, at his home in Lewisport, Ky. He was attending to his practice all of the day before his death, which was caused by some heart

lesion. He was born at Eminence fifty-eight years ago. Served as Surgeon in the Confederate army under Col. Yiltner. After the war he moved to Louisville and was Superintendent of the City Hospital for four years, later removing to Lewisport, where he has continued to practice up to the time of his death.

MISCELLANY.

Missouri Law to Prevent Blindness.—A law was passed in Missouri in 1895 providing, under penalty, that should one or both lids of either eye or both eyes of an infant become red or swollen, or should there be any discharge from either eye or from both eyes, at any time within three weeks after its birth, it shall be the duty of the midwife, nurse or other person having charge of said infant, at once, unless for good cause shown, to report the condition of said eyes to a legally qualified practitioner of medicine.

Missouri Cigarette Local Option Law. Any city, town or village in Missouri existing by virtue of the present general law, or by any local or special law, it was enacted by the legislature in 1895, may, by ordinance or act, prohibit the sale, within its corporate limits, of cigarettes or cigarette wrappers to minors any charter provision to the contrary notwithstanding; and such city, town or village may provide punishment or fines for any person, persons or corporation violating any ordinance authorized by this enactment.

Should Name Disease.—Where an action was brought to recover damages for personal injuries caused by the negligence of the party sued in delivering to the plaintiff, to be washed, clothing contaminated with a contagious venereal disease, the latter being ignorant of its condition, the appellate division of the supreme court of New York holds, *Hatterman vs. Siemann*, decided Feb. 7, 1896, that all that was still needed to state a good case for special damages was to give more specifically the name, nature, character, or other description of the disease alleged to have thus been contracted.

Wafers: Light and Red. One good turn, etc. Flossie (who had overheard conversation between her father's groom and the family doctor): "Ain't you goin' to buy our horse?" Doctor: "No, my dear, I want a larger one." Flossie (reproachingly): "We always take any size baby you bring."

The Art of War. Pat: "Phwat does they use grape-shot fur?" Mike: "Sure, its to give the inimy appendicitis."—*Puck*.

The Formation of Spores on Bacteria. Microscopic color tests show that the spores develop out of a material which is discernible by its resistance to the coloring matter, thus showing its resemblance to the mature spore. It first shows as small grains on the bacteria protoplasm, which grow together into a spore. This resistance tends to prove that the spores not only possess some peculiarly tough tissue, but that there is also some chemic constituent that is responsible for it. *Fortschritte der Med.*, 1895, Nos. 20, 21.

Changes in the Portal Vein in Biliary Lithiasis. Galliard reviews in *Méd. Mod.*, 1895, No. 93, the different cases on record of inflammations, thrombosis, compression and fistulas of the portal vein consequent on the formation of biliary calculi. He recommends in acute disorders of the vein, after thorough cleansing of the intestines and bile duct with calomel, salol, salicyl or naphthol, that an operation be attempted which is contraindicated in chronic cases. This makes it all the more important to treat the trouble in time. *Centralblatt f. Chir.*, February 22.

The Thyreo-proteids. Morin suggests that the thyreo-proteids discovered by Hotkin, might be used to advantage in the infective diseases, like tuberculosis. The atrophy of the thyroid glands usually present in phthisis is his ground for this sugges-

tion and he cites cases of enlarged thyroid glands in which the disease remained stationary. He has experimented with it himself in many cases, but not sufficiently to announce an authoritative opinion, and he urges others to continue experimenting with it on animals immune against tuberculosis, goats, horses, etc., and also on persons, after isolating the antitoxin. —*Centralblatt f. Chir.*, February 15.

New Formation of Nerve-cells in the Brain of a Monkey after Extirpation of the Occipital Lobes.—Vitzou announces that he has accidentally found that the assumption that there can be no regeneration of the central nerve fibers or cells, is incorrect. In February, 1893, he removed both of the postero-inferior portions of the hemispheres in a monkey. In four months the first total blindness began to pass away, and two years and two months later, the animal could see enough to avoid obstacles. At this time the brain was opened again, when Vitzou was astonished to find that the space occupied formerly by the extirpated lobes was filled with a newly formed substance, which tests proved to be nerve fibers and cells, although not so compact as in the normal brain. He believes that the improvement in the sight was due to this regeneration of the nerve fibers and cells. —*Compt. Rend.*, Sept. 16, 1895.

Tuberculous Peritonitis.—Mazzoni reported thirty-five cases of this disease treated with laparotomy, followed by recovery in thirty-three. Two cases required a second operation in eight to ten months. He merely opens the abdominal cavity and empties it of fluid. The second operation was of special interest on account of what was found in the abdomen: The tubercles had almost disappeared, around those that were left there was an inflammatory exudation, and inside there was cystic degeneration. This report was made before the Congress of Surgery at Rome, last fall, and led to a lively discussion whether all forms of peritoneal tuberculosis indicated an operation, whether the simple opening of the abdomen is enough, or whether in the peritoneum a certain amount of irritation should be produced. The members agreed to take note of all cases and compare experiences. —*Centralblatt für Chir.*, February 1.

The Relations Between the Cerebrum and the Labyrinth. Ewald and Hyde have been investigating the after-effects of disturbances in the labyrinth in different animals, which tend to change into substituting phenomena, more or less, and the higher the animal in the scale of nature, the greater this tendency. They removed the cerebrum from some frogs whose labyrinths had already been removed, but found this had a very slight influence on the substituting process, which is insignificant in these animals. Experiments on doves showed that the removal of the cerebrum had a decided influence in preventing it. The scientists consider their experiments conclusive that the cerebrum plays a most important part in these phenomena, and expect to prove it beyond question by the experiments on dogs they are now undertaking. —*Centralblatt f. Chir.*, February 8.

Ozena.—Schestakow's article on this subject treats of the pathology and therapeutics of ozena, with observations of twenty-eight cases treated. He believes that it is a disease *sui generis*, and has nothing in common with other nasal affections, not even with diseases of the accessory nasal cavities. The characteristic rudimentary condition of the nasal muscles is the consequence of a defective development of the bony frame. Where there is a tendency to it, measles is most frequently the starting point. A constant and quite important symptom is the absence of adenoid growths and the small size of the tonsils. None of the theories proposed in regard to its etiology are tenable except the idea of a constitutional predisposition, consequently the author states that general treatment is most effective, and local only palliative. —*Centralblatt f. Chir.*, February 15.

The Vermont "Magnetic Healer." A blacksmith named Bradley Newell, of Jacksonville, Vt., has become popularly known in a large section of New England as a magnetic healer. In one day he treated nearly one hundred patients between two and six o'clock, and the patients beginning to gather as early as seven o'clock. He could not be consulted until ten o'clock, and at that time the hotel looked like a hospital. Invalids arrive by every train: some had to be carried into the hotel, while many used crutches. His alleged cures are attracting great attention. He admits that he has not made many immediate cures, but thinks the patients will find relief later. He has treated over three hundred persons in two days, most of them paying two dollars each. Several of the patients have come three hundred miles or more to see him.

Effects of the Cathode Ray upon the Bacillus of Diphtheria. The bacteriologists of the Health Department of New York city have been experimenting as to the effect of X-rays upon the bacilli of diphtheria and tuberculosis. The experiments were made on Friday, March 20, by Dr. Biggs and Dr. Martin. Saturday, however, Dr. Beebe discovered that the results of the experiments were negative. It was expected that as the bacilli of the diseases are readily killed by exposure to intense light that the X-rays might have a similar effect, but beyond the fact that the bacilli thrived in the beef broth in which they were, no other effect was observed. This seems to be in line with the recent experiments of Nicola Tesla, who found that the X-rays had a soothing and even stimulating effect when directed upon the human brain.

A Two-Headed Female Child.—Mr. James Payn, of London, writes thus to the *Independent* regarding a French monstrosity: "It is said that 'two heads are better than one': in that case the French lady who has presented her husband with a female infant thus endowed, but having only one body, is to be congratulated. It will be much less expensive than twins: the priest, I see, has been compelled to perform a double ceremony of baptism, but that is not charged for: the only extra cost will be in caps and bonnets, and hair cutting. If the young lady marries, or if she does not marry, and takes the veil, she will in both cases, however, require two of them. It is curious that the birth of freaks is a thing to be welcomed or deprecated, according to the position of the parents. In many families a girl with two heads would be considered a downright misfortune. Oriana Adela (for she must have two names if she has been christened in duplicate) would be kept out of sight as much as possible, whereas Sarah Jane would be made a public and extremely profitable exhibition."

Proposed Repeal of Laws Requiring Anti-Alcoholic Instruction in the New York Public Schools. The repeal of laws relative to the teaching in the public schools on the effects of alcohol and narcotics is being actively canvassed before the New York Legislature. At a hearing before the Education Committee, the German athletic societies were represented by Prof. Max Grossman, who opposed the existing law and ridiculed the text-books which have been forced upon the public schools as proper modes of teaching the dangers of the use of alcohol and narcotics.

The next speaker was the Rev. Dr. T. Lewis Bannister, of New Hartford, Oneida County, who favored the repeal of the Ainsworth law. He held it to be not only inadequate to prevent the use of tobacco and stimulants by children, but also believed that the books used endangered the health and purity of the home.

Hamaide's Formol Inhaler. This new inhaler consists of two flasks, one holding a liter, and the other 250 c. c. Carbonic acid is generated in the first, by means of bicarbonate of soda and tartaric acid, and passes into the other flask which contains a solution of formol, producing vapors for which it is the vehicle. The 40 per cent. concentrated solution of formol is

used. One hundred grams of hot water are poured into the small flask, to which the formol is added in quantities from 160 to 800 drops. This produces a solution of 2 to 10 per cent., bearing in mind that thirty-two drops of the 40 per cent. solution represent 1 gram of this solution, or 0.40 grams of formol. The vapors of formol have been found very effective in pulmonary tuberculosis, accompanied by bronchial dilatation, or pulmonary gangrene. They subdue the coughing spells and diminish rapidly and notably the quantity and the fetid character of the expectorations. The odor of the formol can be disguised with 40 to 50 drops of Austrian pine. *Bulletin of the Académie de Médecine*, February 11.

Menthol Snuff. *Public Health* states that Messrs. Burroughs, Wellcome & Co., of London, have issued a new preparation which is likely to be most useful. It is called menthol snuff, but contains not only menthol, but ammonium chlorid, camphor, and one-sixth per cent. of cocain, made up with lycopodium. The local anesthetic and antiseptic action of this remedy is marked, and the form in which it is issued renders it convenient and attractive in use.

A Prospective Fortune for Continuous Medical Services.—The Nawabs and Rajahs of India are at times very open-handed in their dealings with their European medical attendants. "Several cases are, indeed, on record where large sums in the form of fees have thus been paid to the latter. But the most phenomenal instance of the kind which has come under our notice is that which is reported in the *Deccan Budget*. The Nawab Fakr-ul-mulk has, we are told, made a will leaving £600,000, or \$3,000,000 to his medical man. This immense sum will come to the latter on the death of his patient."

The Hypnotic Action of Scopolamin in the Insane. The *New York Medical Journal* contains an abstract of an article on this subject which appeared in the *Medical Week*. Two Russian physicians, Drs. Olterogge and Jurman, says the writer, made a series of experiments with the hydrobromid of scopolamin, and found that the drug possessed a true value as a hypnotic in the treatment of the insane. Administered hypodermically, in doses varying from 0.003 to 0.015 of a grain, it induced in the majority of the subjects a sleep which lasted from three to ten hours. On awakening, the patients appeared much calmer than before the administration of the drug. This effect was especially pronounced in maniacs, but it was not so marked in acute hypomania. In chronic insanity its hypnotic action was also manifest. In delirium tremens, however, it tended only to weaken the patient, and had no hypnotic action whatever.

Anatomy and Treatment of Genu Valgum. A 16 year-old patient treated for this trouble died from an attack of diphtheria (in spite of the serum treatment), and the anatomy of the knee was carefully studied. The joint was decalcified and a frontal section made. The main curvature was immediately over the condyli femoris. The structure of the spongiosa was exactly as described by Wolff. The epiphysial cartilage was remarkably broad and very irregularly shaped. The spreading was principally in the center of proliferation, where the cartilage cells were much enlarged and irregularly placed. The periosteum had healed at the point of the operation, fourteen days before, and the faces of the bone were already quite firmly united. Geissler, who writes this to the *Berl. kl. Woch.*, 1895, No. 48, proceeds to describe the supra condylar osteotomy practiced in Bergmann's clinic, as follows: The flesh is opened as usual, the parts of the bone involved are completely exposed; the chisel, which is not too wide, is directed backward, obliquely to the incision so as not to open the joint. A preliminary wedge cut out of the corticalis ensures a firmer hold for the chisel. The exterior corticalis is not cut but pulled apart. The plaster cast is applied as soon as the wound is sewed up. The femur must not be set in the cast if it is twisted, and a club

foot must be corrected. Out of the fifty-six operations made between 1883-92, only six required the tibia operated upon. Thirty-two were reported later as permanently successful; on only had a stiff joint but six still complain of pain after exertion. The advantage of this method is mainly that the limb can be used in five or six weeks after the operation.

Study of Osteomyelitis with Experiments to Immunize.—A detailed report of sixty-three cases of this disease treated in the Moabi Hospital, at Berlin, is published in the *Deut. Ztschr. f. Chir.* vol. XLII, p. 135. It shows again the fact that it seems to be a disease peculiar to youth, as the patients were under 21 years of age. Three cases were accompanied by periostitis aluminosa and numerous staphylococci were found in the exudation after lancing, thus showing that there is really no difference between this form and the suppurative. Nineteen cases followed an accident and one case a severe wetting. Other cases were preceded by angina, typhoid fever, scarlet fever, a suppurating wound, an ulcer cruris and a carious tooth, one of each. The rest of the cases were what is called primary. Most were treated by opening and draining the abscesses, and the few that were scraped required amputation afterward. The pus was examined in twenty-six cases, and streptococci and staphylococci were found together in seven, diplococci in one, but staphylococci were in all except two, so that this disease can be considered a staphylococcus pyemia of the period of development. Experiments on forty young rabbits with injection of staphylococcus bouillon cultures in the auricular veins, produced suppurative inflammations of the marrow and joints, all containing staphylococci. Injections of streptococci also produced typical osteomyelitis, but staphylococci introduced into the stomach were innocuous. Other animals were immunized with serum from patients, and resisted all attempts to produce the disease, although the data are as yet insufficient to accept this as an absolute certainty.

Accidental Death of a Physician.—The *Press and Circular*, January 29, gives an account of an unusual accidental death of a surgeon and general practitioner of good position. The lethal drug was probably aconite. "The death of a medical practitioner, Mr. John Robinson, of Bridlington Quay, Yorkshire, last week, under peculiar circumstances has been largely commented on in the local press. Briefly, the facts are as follows: Mr. Robinson had under his care a young man suffering from some slight ailment for whom he prescribed a bottle of medicine. After one dose, however, owing to the agonizing effects caused, the patient refused to take any more of the mixture. This surprised his medical attendant, but it led to the latter taking the bottle away and promising to send another mixture of less strength than the first. However, the same effects were produced in the patient after a single dose of the second medicine, and again he declined to take any more. This having been brought under the notice of Mr. Robinson, he visited the patient, and stated that the prescription from which the medicine had been prepared was one that he was accustomed to use every day, and that he himself would not object to swallowing the whole contents of the bottle at once. Suiting the action to his word, he called for some water and proceeded to pour out a large dose of the mixture, which he promptly swallowed. Soon afterward he began to feel ill. He accordingly proceeded home at once, and sent for two confrères. Everything that was possible was done for him; but the symptoms of poisoning rapidly developed, and death took place two hours later. His belief, at first, was that the medicine had contained a strong dose of tincture of ginger, but before he died he expressed the opinion that aconite had somehow been dispensed by mistake in the mixture. Mr. Robinson had been forty years in practice in Bridlington, and had reached the age of 64."

Right of Way to Physicians. An ordinance has been passed in

Chicago granting to physicians' and hospital ambulances the right of way across processions, bridges, etc.

Be it enacted by the City Council of the City of Chicago:

SECTION 1. All ambulances and vehicles belonging to the Health Department, and all ambulances or vehicles belonging to incorporated hospitals recognized by the Health Department as being regular hospitals in the City of Chicago, shall have the right of way in the streets of said city, as against all processions, persons, vehicles or animals, when conveying any patient or injured person to any hospital in the city, or when proceeding to the scene of any accident by which any person or persons have been injured: and any person refusing to yield the right of way, where it is possible, shall be deemed guilty of a misdemeanor, and on conviction thereof shall be fined not exceeding twenty-five (\$25) dollars for each and every such offense. The Superintendent of Police is hereby required to rigidly enforce the provisions of this ordinance. Physicians having a permit, and who shall wear a suitable badge, to be procured from the City Clerk, shall also have a like right of way for themselves and their vehicles in the streets, and shall be allowed, as soon as possible, to cross processions and other public gatherings and bridges, when answering calls for their professional services. The Mayor and City Clerk are hereby authorized to issue, upon written application therefor, a proper permit to any duly registered physician or surgeon, residing or practicing in the City of Chicago, which permit shall not be transferable.

SECTION 2. The Mayor and City Clerk, before issuing any such permit or badge, shall obtain from the State Board of Health a certified copy of all regular practicing physicians, licensed by such Board of Health, and residing or practicing in the City of Chicago, and such permit and badge as above referred to shall only be issued to such physician or surgeon who shall be certified by the State Board of Health as being a regular practicing physician or surgeon.

SECTION 3. This ordinance shall be in force and effect from and after its passage.

Concentrated Foods.—During the past year the agitation in military circles about an emergency ration has extended to the daily press, and from the tenor of many of the articles that have been published it is evident that a misconception of the character of the ration sought for has very generally been entertained. The idea has prevailed that some condensation or concentration of nutritive principles is desired which will enable the soldier to carry in a small bulk enough to support him for a number of days; and the editorial columns of a *medical journal* even have contributed to this misapprehension by discussing the evil effects that would follow the want of the natural distension of the stomach resulting from the continued use of such a concentrated food. Perhaps, also, the advertisements of the meat juices and extracts which are represented to contain in a few teaspoonfuls the nutritive elements of so many pounds of beef have had their influence in fostering the mistaken idea. The ideal emergency ration is really a combination of the proper quantities of the proteids, fats and carbohydrates in a water-free and light weight condition, but capable of again taking up their water during some simple process of cooking which can be done by the soldier on a campaign, with a palatable, easily digested and nutritious diet as a result. The following account of the explosion of "dear little Gustavus Adolphus" by Stephen Leacock in *Truth* may help to explode the unscientific idea of concentrated foods:

The smiling family were gathered round the hospitable board. The table was plentifully laid with a soup plate in front of each beaming child, a bucket of hot water before the faint mother, and at the head of the board the Christmas dinner of the happy home, warmly covered by a thimble and resting on a poker chip. The expectant whispers of the little ones were hushed as the father rising from his chair, lifted the thimble and disclosed a small pill of concentrated nourishment the chip before him. Christmas turkey, cranberry sauce, mince pie—it was all there, all jammed into that little pill, and only waiting to expand. Then the father with deep reverence, and a devout eye alternating between the child and Heaven, lifted his voice in a benediction. At this moment there was an agonized cry from the mother. "Oh, Henry, look: Baby has snatched the pill!" It was too true. Dear little Gustavus Adolphus, the golden-haired baby boy, had

grabbed the whole Christmas dinner off the poker chip and bolted it. Three hundred and fifty pounds of concentrated nourishment passed down the esophagus of the unthinking child. "Clap him on the back," cried the distracted mother. "Give him water!" The idea was fatal. The water striking the pill, caused it to expand. There was a dull rumbling sound, and then, with an awful bang, Gustavus Adolphus exploded into fragments. And when they gathered the little corpse together, the baby lips were parted in a lingering smile that could only be worn by a child who had eaten thirteen Christmas dinners."

Practical Notes.

Effect of Nicotin. Experiments with nicotin injected into a hen's egg (five-tenth milligramme) show that it either kills the embryo or stunts its growth if it survives. *Comptes Rendus Soc. de Biol.* Jan. 12, 1895.

Surgery of the Brain. Postempski described, before the Congress of Surgery at Rome, in October, the results of sixteen craniotomy cases treated last year, and concluded that where there are accidents preceding, with tangible injuries, surgical intervention is a great benefit, even in severe cases, but in cases of diseases without objective lesions, the operation is fruitless. In several cases of epilepsy he scraped the cortex, and wherever there were traces of previous inflammations he secured good results. *Centralblatt f. Chir.*, February 1.

Intubation in Diphtheria. The annual report of the Hanover Linden Hospital, commenting on the 267 cases of diphtheria treated, states that, contrary to the American idea, intubation has not been a benefit in cases of very young children, and is questionable also in many other cases, as it is apt to prevent the coughing up of the false membrane and free expectoration, thus preparing the way for pneumonia. Its many advantages in some cases are acknowledged, but tracheotomy is called the sovereign operation, after all.

Chronic Anemia Cured with Hypodermic Injections of Mercury and Quinin. The *Gazz. degli Osp. e delle Clin.* February 4, contains an account of three severe cases of anemia accompanied by nervous troubles, swollen glands, and in one case chlorosis and convulsions, completely cured with injections of bichlorid of mercury, commencing with 1 millig. a day and increased gradually to $\frac{1}{2}$ centig. Each alternate day $\frac{1}{2}$ gramme bichlorid of quinin was given in its place. During the day $\frac{1}{2}$ gramme of bromid of sodium was taken in water into the stomach. This treatment was continued forty days and then gradually stopped. The cure was absolute in each case.

Formalin in Dentistry. Lepkowski announces in the *Przeglad Lek.*, 1895, Nos. 20 and 22, that he has found formalin very effective in cases of acute pulpitis, when even after the tooth has been filled the pain ceases in a few hours. Also after extraction of the sound pulpa, in cases of incipient periostitis, and where the pulpa is changed into an ichorous mass. He first cleans the tooth as perfectly as possible and then introduces a cotton wad dipped in formalin, which he covers with a staniol plate, on top of which he puts the complete filling. A moderate pain follows for several hours, if the nerve had not been entirely killed. Formaldehyd kills the sound pulpa completely, with no greater pain than accompanies the use of arsenic paste, with this advantage that the tooth can be filled at once, without further cleaning. He hopes that this treatment will be found all that he expects from it at present. *Centralblatt f. Chir.*, February 8.

Nerve Suture and Neurolysis. Wölfler reports seven cases of suture of a divided nerve for paralysis of the peripheral nerves and three cases of neurolysis, with recovery in every case except two, which are still doubtful. One was of the facial nerve after an injury. Five sutures were with direct union, one of them of the radial nerve after complicated fracture, two of the median, one of the facial, and one of the plexus cervicalis V and VI. The two indirect unions were of the radius

in one and of the peroneus in the other. These two are the doubtful ones. One case of neurolysis was in the peroneus after osteotomy, and the others of the radial nerve. Neugebauer is soon to publish a complete work on this subject. *Centralblatt f. Chir.*, February 22.

Argonin. The investigations of Liebrecht, Meyer and Jadasohn have established the fact that argonin, like nitrate of silver, is destructive to bacteria, and especially to the gonococcus, while it does not cauterize or burn the tissues like nitrate of silver. It has been employed with the best results in cases of gonorrhea in both sexes (in a 1 or 2 per cent. solution). It seems to lack astringent properties and therefore must be supplemented by something else in catarrhal cases. It is made by transposing casein sodium with nitrate of silver, which produces a powder soluble in warm water. To dissolve it, wet first with a very small quantity of cold water, until every particle is moistened, and then warm it on a water-bath, until it is all dissolved. Fifteen grams argonin contain as much silver as one gram nitrate of silver. *Ther. Wochensh.*, February 16.

To Determine the Amount of Alkali in the Blood. Limbeck describes his method in the *Wien. med. Blätter*, 1895, p. 295, as follows: "It is based on the effect of free acids and alkalies on the albuminoids: 200 c.c. water is heated to the boiling point when one-tenth HCl is added and 5 c.c. blood serum is dropped in, one drop at a time. To this is added with certain precautions one-tenth solution of soda, until a flaky precipitate is deposited. By subtracting the volume of soda from the volume of acid, a standard is obtained for the amount of affinity between the serum and the acids. The blood is treated in the same way and the albuminoids play no part in the affinity, which is the special advantage of this method. This independence of the amount of albuminoids is shown by further experiments with solutions of sodium carbonate and sodium phosphate, which are substituted for different quantities of albumin. The alkali remains at the same figures, while in litmus tests the amount of alkali shows an increase with increasing albumin. *Centralblatt f. Phys.*, February 22.

Glycerin Extract of Bone Marrow. According to the *Medical News*, March 14, Dr. Allen McL. Hamilton strongly maintains the value of glycerin as a solvent for bone-marrow in the treatment of pernicious anemia, chlorosis and hemophilia, and that the cases in which the treatment has been unsuccessful have not been those treated by the medullary glycerid, as claimed by an editorial writer for that journal. Dr. Hamilton adds: "So far as I can learn, there is but one other writer who takes this view of the case. On the other hand there is a large number of physicians who have had the happiest experiences with the preparation originally advocated by Danforth. Since I first used the glycerin preparation (considerably over a year ago) I have never had any bad results, and nothing worse than an occasional intestinal colic; and I have given it to many anemic and debilitated people with results that have been in every way gratifying. Of course there are poor preparations, for the process of maceration of the bones and extraction of the marrow is a laborious and slow one, and the temptation to manufacture weak products is very great."

Cantharidate of Potassium in the Treatment of Cutaneous Tuberculosis. The *New York Medical Journal* quotes from the *Annales de Dermatologie et de Syphilologie*, a case of cutaneous syphilis in the right hand and wrist. At the time of beginning the treatment with the cantharidate of potassium there was no albumin in urine, and the formula for the injections used in the case by the practitioner, Dr. Gaston Branthomme, was the following: Cantharidate of potassium, 0.0015 of a grain; cocaine hydrochlorid, 1.5 grain; distilled water, 150 grains. Eight injections of a cubic centimeter each were made up to the 14th of June (a period of two weeks), another of two

cubic centimeters was given on the 12th of June. The punctures were rather painful and an abscess formed around one of them. The first two injections were followed by a rise in temperature to 103 degrees and 102.1 degrees F. There was a local reaction which manifested itself by a rather copious exudation. This, however, did not occur at the third injection, and cicatrization took place very rapidly. At no time, says the author when the urine was examined was there any trace of albumin found. At the present time cicatrization is perfect, and the patient is in excellent health.

Diabetes Treated by Pancreas Extract.—The *British Medical Journal* quotes Dr. Bormann, of Vienna, as holding to the view that pancreas may be successfully exhibited in those cases of diabetes that are caused by an atrophic condition of gland. This treatment is a form of therapeutics by substitution. Bormann records a case in which a definite result was obtained by pancreas therapeutics. The patient was a man of 30, who had for many years suffered from general symptoms with cough and furunculosis. Physical examination showed the condition to be one of diabetes mellitus, with chronic bronchitis and visual complications. About 3,600 c.c. of urine having a specific gravity of 1035-1048, and containing 40 grammes of sugar, were passed daily. For twenty-four days he was treated first by dieting alone, then with the addition of apomorphin, salicylate of bismuth and opium. These reduced the quantity and specific gravity somewhat; the amount of sugar fell from 30 to 110 grammes daily, but the patient lost weight. He was then put on one ox's pancreas (roasted); after a week he stated that he could not go on eating it, so the juice was expressed and given daily per rectum. Ten days later 1½ c.c. of pancreas extract subcutaneously was substituted for this. When he left the clinic after five weeks' pancreas treatment the sugar was below 30 grammes daily, the minimum being 14.6. The patient was much better in himself, his bodily strength had considerably increased, he had gained eight and one-half pounds in weight, and the thirst, together with the daily excretion of urine, had greatly diminished.

The Reprehensible Heroism of Freeing a Diphtheritic Obstruction by Suction.—The *British Medical Journal*, February 29, mixes mild blame with reluctant praise in a case of this kind: Dr. Ernest Helby, resident medical officer at the Croydon Fever Hospital, lately saved a child's life by sucking the diphtheritic membrane from its throat after tracheotomy; he caught the disease, suffered some paralysis, and was for a time in danger of death. "We are happy to say," says the *Journal*, "that he has now, under the antitoxin treatment, made good progress toward recovery. It is difficult to say the right thing when one hears another instance of this act of devotion; proverbs and texts fight in one's mind against each other, and it is hard to venture to blame him at all, and hard to praise him without a cautionary reserve: but of one thing we are sure, that he deserves and has won respect and admiration due to a man who is ready to lay down his life for a child. There is a story somewhere in history of a man who saved his country by methods of his own, which did not meet with the approval of the Government. The Government crowned him, honored him and gave him a triumphal procession, and then executed him for breaking the law of the land. We would mix a little reproach with a great deal of praise for Dr. Helby, and tell him that other lives as well as the child's life are bound up with his own, and we hope he tried suction with a syringe before he put his lips to the tube, and did all that was possible to avoid the danger of infection. But it is pleasant to stop our criticism at this point, and to assure him of our most sincere admiration of his absolute devotion of himself to save the life of a child."

Hospital Notes.

EIGHTH ANNUAL REPORT OF THE METHODIST EPISCOPAL HOSPITAL OF BROOKLYN. A well-composed report of 250 pages represents the work of the above named charity for the year

ended Oct. 31, 1895. There has been an increase of the number of beds and amount of work, compared with the previous year; seven more pupil nurses were admitted to the training department, nearly two hundred admissions above 1894, and 1,000 more hospital days. Five of the nine buildings belonging to the original plan have been completed, a sixth will be added in the coming year; leaving one-third to be gradually reduced as the "sinews of peace" become active. Expenses were \$45,000, receipts \$45,500; endowment funds yielded \$9,000; pay of patients \$13,000; gift of city for ambulance and accident cases \$6,000; other sources, largely by appeal to the denomination, \$17,500. Total patients treated, 1,098; remaining at date of report, 76; mortality, 10.46 per cent. The rate of mortality was very nearly identical upon both medical and surgical services, but the number of surgical cases was nearly thrice that of the medical branch. Total hospital days were 25,491; average number of days per patient, 23.21; total number of non-paying days, 19,000, nearly; daily cost for food per person, \$0.24; daily cost of maintenance per person, \$0.66; daily cost per patient, \$1.40. Ambulance service, for which the city makes an appropriation of \$1,200, attended to 1,132 calls, an increase of 139; one-third of the cases received treatment in the hospital. The dispensary department, which had been closed about four years, has been reorganized, having been formally opened in November, 1895. An operative surgical clinic, open to all medical men, has been held every Wednesday. The pathologic department conducted 49 post-mortems, a trifle less than one-half the number of deaths reported. The training school for nurses had a graduating class of eight.

Detroit Notes.

THE WAYNE COUNTY MEDICAL SOCIETY, at its regular meeting, March 19, listened to an interesting paper by Dr. Jay W. Morrison, entitled, "Experiences in the Late Smallpox Outbreak." The Doctor based the opinions formulated in his article upon the experience that he had had as an associate of the health officer, and also that which he had had by being brought in contact with over 200 cases in the last two years. The Doctor did not consider that we had had an epidemic, and wished in several instances to take issue with the authors as to the diagnosis of smallpox and its course. The Doctor said that he did not care about using the word varioloid; he believed that the disease was communicable at any period, in its first stage or any time before the papules had appeared. He also believed and cited cases where patients had died before the papular stage had been ushered in. In his experience he had not had as good results with the hemorrhagic variety as some had reported; but he believed that it was on account of the divisions that some had made. He restricted the term hemorrhagic to that form where there was hemorrhage from the kidneys and from the intestinal tract. The Doctor did not think it was always such an easy matter to make a differential diagnosis between chickenpox and smallpox, and in this connection he mentioned, what is contrary to the leading authorities, that he had seen a number of cases of chickenpox in which the papules were found both upon the palms of the hands and soles of the feet, and the subsequent history of the cases confirmed his diagnosis of chickenpox. One point that was emphasized was that in chickenpox we do not have fever upon the first or second, but it commences upon the third day. In smallpox the fever commences upon the first day and rises to 102, 103 or 104 degrees. In chickenpox it may be nearly as high as this upon the third or fourth day, but not before. The Doctor remarked that we do have chickenpox in adults, although it is an exception. Dr. Morrison does not believe that there is any way by which the pitting of smallpox can be prevented. He had tried all forms and modes recommended and had failed, and thought by inference that the trouble was exaggerated. The course of the fever and the amount of papu-

lar eruptions could be somewhat modified by antiseptic dressings. The Doctor cited cases that had been immune from smallpox for a time without vaccination, and had subsequently contracted the disease. He remarked that he had not seen a smallpox case in the morgue with a vaccine mark; and he also mentioned a number of cases where vaccination had been made some years before and the patient came down with smallpox; that the disease ran a short course, and with these two last truths verified many times in his observation, he was convinced that the only way to stamp out the disease was to have all persons thoroughly vaccinated, and he predicted that when this was done that we would not only be rid of epidemics of smallpox, but isolated cases would be rare. The paper was discussed by Drs. W. J. Brand, D. O. Donovan, F. B. Tibbals, W. T. Cody, T. J. Parker, R. W. Gillman and E. B. Smith.

THE DETROIT MEDICAL AND LIBRARY ASSOCIATION at its regular meeting, Monday, March 16, listened to a practical paper, by Dr. A. E. Carrier, entitled, "Use and Abuse of Arsenic in Dermatologic Affections."

AT THE REGULAR MEETING of the Detroit Academy of Medicine, last Tuesday evening, the 17th inst., Dr. Don M. Campbell read a paper entitled, "Can Exophoria be Cured Without Operation?" After taking up historical review of the subject, he explained what exophoria is, and its relation to accommodation. All cases of exophoria, especially when associated with hypermetropia or hypermetropic astigmatism, should receive one of the following treatments: Correction of refractive error; general systemic treatment of a tonic alterative with hygienic care; gymnastic exercises of the internal recti muscles by means of prisms used after the Gould or Savage method, the former being preferable; the surgical treatment. In the majority of cases the exophoria can be cured without resorting to operation. Perhaps 5 per cent. will require tenotomy or advancement.

HEALTH OFFICE REPORT for week ending March 21: Deaths under 5 years, 38, total 96. Births, male 44, female 54, total 98. Contagious diseases: Diphtheria, last report 12, new cases 13, recovered 3, died 8, now sick 14. Scarlet fever: Last report 19, new cases 6, recovered 4, died none, now sick 21. Smallpox: Last report 3, new cases none, recovered 1, died none, now sick 2. Measles: Last report, 3, new cases none, recovered 1, died none, now sick 1.

Washington Notes.

WEEKLY REPORT OF THE HEALTH OFFICER.—The number of deaths during the last week, according to the report of the health officer, exceeded those of the previous week slightly over 7 per cent. A review of the meteorologic conditions shows that the average temperature was at the freezing point, and that a constant range of low barometer prevailed with a high relative humidity. The death list, under these conditions, went up from 112 to 121, and the death rate from 21.2 to 22.8. During the corresponding period of last year it was 19.4.

COMMISSIONER'S REPORT ON THE VIVISECTION BILL. After cutting out all sections that were not approved by the medical fraternity, the Commissioners have favorably reported the House bill 4446, for the further prevention of cruelty to animals in the District of Columbia. They recommend that the title of the bill be known as "A bill to regulate vivisection in the District of Columbia."

MEDICAL SOCIETY.—At the Medical Society meeting held on the 18th inst., Dr. Stone read a paper on the treatment of movable kidneys. Dr. Bowen presented a ruptured tubal pregnancy, an ovarian cyst and hysterectomy for fibroids.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—The 243d meeting of the Society was held on the 20th inst. Dr. Geo. N. Acker reported a case of congestion of the cord with recovery, followed by typhoid fever with some interesting features. Dr. M. F. Cuthbert reported a case of post-partum hemorrhage. Dr. H. L. E. Johnson presented a working model

of the Pitkin operating table in use at the Emergency Hospital. It is constructed entirely of metal and can be absolutely sterilized. It has all the features of the Harvard chair, can be elevated or lowered two feet by a screw crank. The entire top surface is hollow, through which hot water is kept flowing from a twin spigot. The patient is thereby kept warm during prolonged operations. The table was devised and made by the engineer of the Emergency Hospital and has been in constant use during the past eighteen months.

COMMITTEE ON EPIDEMIC DISEASES. The name of the Committee on Epidemic Diseases, U. S. Senate, has been changed to "Committee on Public Health and National Quarantine."

Louisville Notes.

PHARMACY. The annual commencement of the Louisville College of Pharmacy was held on the 17th at Macauley's Theater. The graduating class numbered eighteen, the first honor man, H. F. Bierman, of Little Rock, Ark., received 543 in his final examination out of a possible 570, the highest average ever received at the college.

ACADEMY OF MEDICINE. This Society held an open meeting in their rooms at the College of Pharmacy Building, the occasion being a popular lecture by Prof. E. H. Mark, Superintendent of the Louisville Public Schools, formerly Professor of Physics and Chemistry in the Boys' High School. The subject of the lecture was "The Roentgen Rays," and Professor Mark spoke very entertainingly and instructively upon heat, light, and electricity, gradually leading up to the subject of the X rays. He paid a glowing tribute to the discoverer of the Crookes tubes, and exhibited the tube with which Professor Marple has been able to take the successful picture of the bullet imbedded in the hand of a patient at the University Dispensary, afterward removed by Dr. W. O. Roberts.

SMALLPOX. State Sanitary Inspector Long has been sent to Sulphur, Ky., to investigate a rumor that there is an outbreak of smallpox at that place. Sulphur was the home of the patient who died last week at the Eruptive Hospital. There were several large families exposed to this case before his isolation, but the timely vaccination of everyone in the neighborhood by Dr. White, has limited its spread. Three houses are flagged with the yellow flag, containing eight cases of varioloid. Dr. Long on his return, reported the outbreak at Sulphur, supposed to be smallpox, was varicella.

MEDICO-SURGICAL SOCIETY. This Society was entertained by Dr. S. G. Dabney on the 20th inst., his essay being upon the "Etiology, Prognosis and Treatment of Acute Middle Ear Disease."

THE PUBLIC SERVICES.

Circular No. 1.

WAR DEPARTMENT, SURGEON GENERAL'S OFFICE,
WASHINGTON, March 13, 1896.

To secure uniformity in carrying out the provisions of G. O. No. 9, Adjutant General's Office, March 13, 1896, medical officers will be governed by the following general directions:

The instruction necessary to enable company officers to drill the enlisted men of their companies "in the duties of litter bearers and methods of rendering first aid to the sick and wounded" will be given chiefly by practical demonstrations, made in their presence, of the litter drill and methods of rendering first aid.

The prescribed drills of company bearers and of the detachment of the hospital corps should be utilized for this purpose. Especial attention should be given to the instruction in first aid to the sick and wounded, and the practical demonstrations should include methods of arresting hemorrhage, of applying the dressings contained in the first aid packet, of immobilizing a fractured limb, of resuscitating those apparently drowned, etc.

These practical demonstrations should be accompanied by full explanations of the reason for adopting the methods recommended. The practical instruction should be supplemented by lectures designed to convey all essential information with reference to the anatomy of bones and blood vessels; the causes and treatment of syncope and of heat exhaustion; the differential diagnosis and treatment of sunstroke; the rationale of the various measures of first aid to the sick and wounded, etc.

It is the intention that in time of war every officer and enlisted man shall carry a first aid packet, to be furnished by the medical department. These packets will be obtained by the surgeon of each post, upon special requisition, and will be supplied by them to company commanders for purposes of instruction. The allowance for this purpose will be twenty packets for each company of infantry, battery of artillery or troop of cavalry. The dressings contained in these packets can be used repeatedly for the practical instruction of officers and enlisted men, and after being used for this purpose should be made up into packets of

the original form. These packets are expendible, but great care should be exercised to prevent any unnecessary expenditure, and officers will be held strictly accountable for their proper and economical use for the purpose indicated.

The drill regulations of the hospital corps will be revised, as soon as practicable, to make them conform with authorized changes in the equipment of members of the hospital corps (absence of side arms) and in the litter (detached litter slings).

G. F. M. STERNBERG,
Approved: Surgeon General, U. S. Army.
DANIEL S. LAMONT, Secretary of War.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the three weeks ending March 21, 1896.

Asst. Surgeon J. C. Rosenbleuth, detached from the naval laboratory and ordered to the "Raleigh."
Asst. Surgeon F. M. Shipp, detached from the "Raleigh" and ordered to the "Vermont."

Surgeon P. M. Rixey, ordered to the naval dispensary, Washington.
Asst. Surgeon H. La Motte, detached from the naval hospital, Chelsea, Mass., and ordered to the receiving ship "Franklin."
Surgeon G. E. H. Harmon, detached from the naval dispensary, Washington and ordered to the naval academy.
P. A. Surgeon C. H. T. Lowndes, ordered to the Washington navy yard.

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the sixteen days ended March 16, 1896.

Surgeon J. B. Hamilton, granted leave of absence for four days, March 16, 1896.

Surgeon Fairfax Irwin, to inspect Service at Havana, Cuba, and quarantine stations in the South, March 2, 1896.

P. A. Surgeon P. M. Carrington, granted leave of absence for thirty days, March 16, 1896.

Asst. Surgeon J. A. Nydegger, to report at Bureau for instructions, March 6, 1896. To proceed from Washington, D. C., to South Atlantic Quarantine and assume command, March 7, 1896.

Asst. Surgeon Emil Prochazka, granted leave of absence for ten days, March 11, 1896.

BOARD CONVENED.

Board to examine and report on schedule of subsistence for seamen on merchant vessels of the United States, to meet in Washington, D. C., March 16, 1896. Surgeon P. H. Bailhache, chairman; P. A. Surgeons C. E. Banks and J. J. Kinyoun, recorders.

Change of Address.

Ambler, C. P., from Canton, Ohio, to care The Winyah Hotel and Sanitarium Co., Asheville, N. C.

Ash, E. E., from Chicago, Ill., to Goshen, Ind.

Bouton, W. C., from 131 53d St. to 320 E. 57th St., Chicago.

Craig, S. S., from Chicago, Ill., to Alamosa, Colo.

Dickson, W. L., from Rust Point to 208 Edwards St., Shreveport, La.

Houghton, E. F., from Claremont to Rochester, N. H.

Ingals, Ephraim, from 34 Throop St. to 4753 Grand Boul., Chicago, Ill.

Ingals, E. Fletcher, from 509 W. Adams St. to 4757 Grand Boul., Chicago, Ill.

Legge, J. H., from Pittsburg, Pa., to Aurora, Preston Co., W. Va.

Motter, Murray Galt, from Lancaster, Pa., to Head of 30th St., N. W., Washington, D. C.

Paquin, The Paul, Laboratories, from 1635 S. Grand Av. to 3536 Olive St. St. Louis, Mo.

Perkins, Jay, from 416 Broad St. to 78 Broad St., Providence, R. I.

Phillips, Ellis, from 424 Mulberry St., to 711 Madison Av., Seranton, Pa.

Prince, L. H., from 1348 N. Halsted St. to 51 Lincoln Av., Chicago, Ill.

Small, L. M., from St. Louis, Mo., to Decorah, Iowa.

ADDRESS.

LIFE AND TIMES OF DOCTOR REUBEN D. MUSSEY.

Public address, by invitation, to the Graduating Class of the Ohio
Medical University, Columbus, Ohio, March 17, 1896.

BY JOHN B. HAMILTON, M.D., LL.D.
CHICAGO.

Mr. President, Ladies and Gentlemen:—I thank you for this gracious reception and your kindly words of introduction. But I do not feel like a stranger in this great State of Ohio. My great-grandfather, a Revolutionary soldier, settled at Point Harmar, subsequently helped defend the Territory against the Indians, and was a member of the Second Legislative Assembly of this State. My mother was born on the beautiful banks of the lower Muskingum, and my grandmother on my father's side was the daughter of Captain Benjamin Brown, one of the earliest settlers of Athens County, and whose numerous descendants still inhabit the Ohio River Valley. Therefore, in speaking in this famous Capitol, to this distinguished audience, I feel that I have a closer personal interest in this people than my friend Dr. Reed was aware of when he asked me to address you on this occasion.

Nothing interests the average man so much as himself, or the affairs of his immediate neighbors, and I have therefore chosen as the subject of my address this evening, the life and times of one of the most learned and distinguished of the sons of the Buckeye State, namely, that of Professor Reuben D. Mussey, of Cincinnati. It is true that he was only an adopted son of Ohio, but he was one of the earlier educators of the medical men who now constitute the glory and pride of its medical profession. His teachings and his example have therefore become a part of the intellectual property of his immediate pupils; their associates and successors.

Biography has ever been considered one of the most fascinating branches of historical study, not only on account of the particular life chosen as the topic, but on account of its ennobling and stimulating effect on those within its influence. We naturally desire to emulate the virtues of our hero, and the record of his achievements stimulate the ambition to the performance of greater deeds, if possible.

The life of a great surgeon is full of scenes of pathos, of memories of triumphs over disease, of critical and anxious moments, of occasions where human life literally depends upon a thread and of times when boldness, courage, skill and gentleness are each in turn called into play. In lauding the science of biography, the elder D'Israeli takes exception to the statement of a periodical critic, that there was "something melancholy in the study of biography, because it is a history of the dead." He designated as "sentimental biography" that variety of biographic writing

which seeks only eulogy, which is usually compiled "by some domestic friend, or by some enthusiast who works with love." It is distinct from a *chronologic* biography, for it searches for the individual's feelings amidst the ascertained facts of his life; so that facts which occurred remotely from each other are at once brought together. This "sentimental" is distinguished from the *autobiography* which being in the hands of an interested, if not a suspected witness, is not always trustworthy history.

To point the moral of the story of such a life as that of Professor Mussey it is not necessary to be either sentimental or unduly eulogistic. The period of his life covers the most interesting period of the history of surgery, and he himself was a factor in the speedy popularization of the greatest discovery in its relations to practical surgery, of any in all antecedent history, namely, that of anesthesia. The famous Professor South, of London, writing a postscript to *Cheilus' Surgery* in 1847, says:

"The year 1846 seems in a fair way to be known as the *annus mirabilis* of surgery. The profession and the public in both hemispheres are in a complete ferment, consequent on the discovery by Morton, an American dentist, of a mode of producing insensibility during which an *operation may be borne without pain*, nay, even rendered so agreeable as to induce a desire for its repetition."

What a change was brought about! Before the days of anesthetics no operation of election was performed without a long course of preparation; spare diet, purging and frequent blood-letting were the means resorted to, to prepare the patient for the ordeal; laudanum or morphia the night before, and large doses of brandy during the operation, and not unfrequently the cries and groans of the patient added much to the terrors of the operation itself. The blood-letting practice had perhaps reached its maximum height in 1832-33, when Mr. Wardrop, a noted London surgeon, in his lectures on surgery published in *The Lancet* gravely proposed that to prevent suffering during an operation a patient should be bled to faintness, and the operation performed during the swoon! Hypnotism, or, as it was then called, mesmerism, was frequently made use of, but South characterized it as "foolery." But starvation diet was then, as now, a favorite hobby, and Sir Astley Cooper told an excellent story of Abernethy, who is said to have prescribed blue pill and ipecac for everything, and "ordered his patients to eat only three ounces a day, and not to drink when they eat. A patient of his said to me, 'I am a proselyte to his doctrines; does he practice what he recommends?' I said, 'I will give you a faithful account of his dinner to-day, for I dined with him at the Free Masons' tavern. I sat next to him. He took turtle and punch, fish, venison, champagne, pastry, cheese and 'now,' said he, 'waiter, give me a glass of brown stout.' 'After this,'" said Sir

Astley, "he took his wine moderately as we all did." The patient on receiving an account of this dinner of Abernethy's, refused any longer to starve himself, and ate and drank to his heart's content ever afterward.

Reuben D. Mussey, M.D., LL.D., was born near Rockingham, N. H., June 23, 1780, and was the son of Dr. John Mussey, who resided in Pelham Township. While yet a child his father removed to Amherst, N. H., and he had the benefit of some instruction in the winter at the district school. His father taught him elementary Latin, and when he was fifteen years old he entered the Aurean Academy at Amherst. In 1801 he entered the junior class in Dartmouth College and was graduated therefrom in August, 1803. He then began the study of medicine as a pupil of Dr. Nathan Smith, the founder of the Medical School of New Hampshire, the father of Nathan R. Smith.

REUBEN D. MUSSEY, M.D., LL.D.

Fourth President of the AMERICAN MEDICAL ASSOCIATION.

Dr. Smith was a man of more than ordinary ability, and one of his biographers states that "no physician either before, during, or since his time has had so wide a sphere of popularity, and he was as well known in our times almost as the resident physicians and clergymen are." His career was characteristic of the times. When he was a youth he enlisted in the Vermont militia and served in the Indian campaign, and by accident having seen a surgical operation, became deeply interested in it and desired to become a surgeon. Consulting Dr. Josiah Goodhue, then considered the most eminent surgeon of the locality he was informed that if he would place himself under the tuition of a person competent to instruct him and obtain as much literary information as would enable him to enter the Freshman class of Harvard College, he would accept him as a student. He followed the ad-

vice, placing himself under the care of the Reverend Mr. Whiting, of Rockingham, Vermont, until qualified to comply with the conditions raised by Dr. Goodhue. After studying three years under his preceptor, he began to practice, but finally suspended it and attended medical lectures in Harvard College. Here he received the degree of Doctor of Medicine, and in the organization of the medical institution in connection with Dartmouth College the appointment of Professor of Medicine was conferred upon him. Several years after, he went to Edinburgh and attended medical lectures under the illustrious Monro and Dr. Black. On returning he continued his instruction and practice at Hanover, N. H., until the autumn of 1813, when he was made Professor of Theory and Practice of Physics and Surgery in the Medical Institution of Yale College, established in that year at New Haven. Dr. Smith also lectured on the same branches at Dartmouth College, the University of Burlington, Vt., and the Medical Institution of Brunswick College in Maine. So active a professor, and one so popular as Dr. Smith, must have impressed his personality upon Dr. Mussey very strongly, and there is no question but the bent of Dr. Mussey toward surgery was in no small degree influenced by association with Dr. Smith.

Dr. Mussey received the degree of Bachelor of Medicine in 1805 from the Medical Institution of Dartmouth, and began the practice of medicine in Essex County, Mass., at Ipswich. After three years he went to Philadelphia and became a private pupil of Prof. Benjamin S. Barton and attended his botanical lectures, as well as the lectures in the medical course proper. In 1809 he was graduated M.D. from the University of Pennsylvania. He heard the lectures of Drs. Benjamin Rush, Physick, Dorsey, Barton, Woodhouse and Chapman. Dr. Mussey being an indefatigable student and a hard worker, was not inclined to accept all the theories that were offered him without more thorough investigation, and among them he had been taught by Dr. Rush that there was no absorption from the skin. Young Mussey immersed himself in a bath in which three pounds of madder were diffused in sufficient water to cover the body and limbs, and he found this coloring matter in the urine. He repeated his experiment and finally wrote his thesis on the subject of "Skin Absorption," which was received with pleasure, but not with entire approval, for Professor Rush, not willing to be caught in error by one of his own pupils, had several experiments made with the result of only partially proving Dr. Mussey's theory. Dr. Mussey then continued for a long time to conduct experiments for the purpose of proving his theory. Among others, on one occasion he immersed himself for three hours in a strong solution of nutgall, and afterward in a strong solution of iron for three hours more. But this experiment was negative, for no ink was found in the excreted urine. He then opened a vein in his arm for the purpose of testing the blood, but could not discover it, although some peculiar appearances were found which indicated that a change had taken place, due to the absorption of the iron; but he had already proved his main proposition.

After his graduation in Philadelphia, Dr. Mussey returned to Massachusetts and practiced in Salem five or six years, and in 1814 was appointed Professor of Theory and Practice of Physics in the Medical School of Dartmouth College, succeeding his preceptor, Dr. Nathan Smith. Here he gave a course of lectures on chemistry for one session, and in 1819 was appointed

¹The Life of Sir Astley Cooper, Bart., by Bransby Blake Cooper, London, 1843.

to the Professorship of Anatomy and Surgery, and in knowing Dr. Mussey one could well understand that at this time he conscientiously began anew the study of anatomy in order to give two daily lectures to the pupils during the term.

In 1829 he visited Europe, spent several weeks in London and attended clinics in Paris. Dr. Mussey also lectured in the Medical School of Maine, and in 1836-7, after the close of the session of the College of New Hampshire, he went to Fairfield, N. Y., to give lectures on surgery in the College of Physicians and Surgeons there. This school was subsequently removed to Geneva and afterward became a famous institution.

In the fall of 1838 Dr. Mussey accepted an invitation to become Professor of Surgery in the Medical College of Ohio, at Cincinnati, founded in 1821, and he, with his family removed to that city. At this time the means of travel was by canal to Pittsburgh and from Pittsburgh to Cincinnati via boat. Climatic reasons alone induced the popular professor to cross the Alleghenies. His health had become delicate and he, somewhat worn by a long, laborious practice in the cold and rigorous climate of New England, looked favorably on the balmy air of the Ohio Valley and looked forward with pleasure to his new field of labor. For fourteen years Professor Mussey practiced, lectured and taught in the Medical College of Ohio, and during this period had charge of the Marine Hospital in Cincinnati, but at the end of that time he resigned. A few months later he was asked to become Professor of Surgery in the Miami Medical College, founded in 1853, which he accepted, and at this time also had charge of the surgical wards of St. John's Hospital.

Dr. Mussey's first remarkable operation was the ligation of the carotids for aneurysmal tumors of the head in which the operation was successful. He repeated the operation 1854.²

This is hardly the place to repeat the brilliant record of Dr. Mussey's important surgical operations. He was one of the early operators for ovarian disease. He removed an hypertrophied tongue in the case of a boy of thirteen, the tongue at the time of operation measuring eight inches in circumference where it issued from the mouth.

Another case of Dr. Mussey was one of osteosarcoma which necessitated the performance of an operation for the removal of the entire shoulder blade and collar bone. This was the second case on record, the first operation having been performed by Dr. Dixie Crosby in 1836. The date of this operation was October, 1837. It was repeated in 1845. He removed the lower jaw without implicating the facial nerve, and it is said by his biographer³ that "while in charge of St. John's Hospital, then having numbered considerably beyond three-score and ten, we saw him ligate the carotids with the same nerve as when in the prime of life."

An ardent temperance lecturer and one much interested in hygiene, there is no question of the value of his influence and example on the young men of his adopted city and State, not only those who attended his own lectures, but as well those to whom the influence of his pupils reached.

He died in Boston in 1866 at the advanced age of 86 years—years full of fruitful labor, of conscientious

work. He was the fourth President of the AMERICAN MEDICAL ASSOCIATION, and always took an active interest in its meetings.

Dr. Mussey was an early advocate of the bilateral operation for stone, and according to the report of the Committee on Surgery in Vol. 1, Transactions of the AMERICAN MEDICAL ASSOCIATION, as early as 1848, he had reported a series of sixteen surgical operations under the use of chloroform,⁴ "without its being followed by a single unpleasant symptom."

Dr. Mussey himself made the report of the Standing Committee on Surgery in 1849, and in that report we find an account of a vaginal hysterectomy performed by Prof. Paul F. Eve on April 16, 1850. This is believed to be the first operation of its kind on record. One of the most elaborate papers of Dr. Mussey was that on "The Effects of Alcoholic Liquors in Health and Disease," which will be found in Vol. 8 of the Transactions for 1855. In this paper there is shown an intimate knowledge of physiologic chemistry as then understood and also of the toxic effect of alcohol, very remarkable for that period. He was the first to demonstrate the possibility of bony union taking place in intracapsular fractures of the humerus. In his trip to Europe, which I have already mentioned, he carried with him a specimen of a femur which had been sawn through showing bony union. He showed the specimen to Sir Astley Cooper among others, who asserted his disbelief that the bone had ever been fractured. His reception by Sir Astley was afterward quoted by Dr. Mussey as showing the intolerance and bigotry of one of the great masters of the profession.

As a writer Professor Mussey was not prolific, but what he did write was characterized by clearness of expression, accuracy and entire truthfulness. He did not find it necessary to go into specious case-writing that might be called Arabian Nights' literature, wherein, judging from the number of cases reported by one author, he must have averaged from ten to fifteen a day for a period of several years, an utter absurdity, but when Mussey reported a case, there was no earthly doubt in the mind of anyone who heard the report that the case actually existed. I need not say to you, young gentlemen, who are now leaving this institution, that next to faith and trust in God, a virtue which most becomes a practitioner of our noble calling is that of *truth*; and we have, I regret to say, arrived at a period in our literature when we must either throw out a large mass of the statistics that are furnished us, or else accept them only from men of known probity in such matters.

As a citizen Dr. Mussey was deeply interested in the political affairs of his time, and as all good citizens should do, took a personal interest in the affairs of his city, his State and his country. I have little respect for the false sentiment that keeps the physician out of touch with the remainder of his fellow citizens on political questions. He need not and ought not to be offensive to his clientele, but he should have a clear view of what the best interests of the country require, and throw his influence in favor of those interests.

I do not know exactly how it came about, but there has been a great change in the feelings of our countrymen since the days of Dr. Joseph Warren and Dr. Benjamin Rush.

In those times, those great men of our profession addressed public meetings on public affairs. One

² See Eve's remarkable cases in surgery, p. 650.

³ Transactions AMERICAN MEDICAL ASSOCIATION, Vol. 18, p. 317.

⁴ Transactions AMERICAN MEDICAL ASSOCIATION, Vol. 1, p. 234.

sealed his devotion to his country with his life's blood at Bunker Hill, and the other gave his time and talents to the organization of the Continental Congress, and signed our immortal Declaration of Independence. Now, I regret to say that our profession, in common with many other of our well to do parlor-patriots, especially in the great cities, do not take the interest they should; as if love of country, and interest in its affairs, were private sins to be kept as a profound secret in the breast of the unfortunate possessor.

No! young gentlemen! Take the stand in regard to public affairs in the community that your education entitles you to take; give your influence freely to that party you deem to be right. When all educated men, the clergy, and the medical profession, join the profession of law, in giving suitable and dignified expression to their views on public matters, all will be well with the Republic.

There is another side to the character of Dr. Mussey which I have only lightly touched upon, and that is his patriotism, his generosity and constant services to the poor, and his secret benefactions. He seemed always to have in view the Hebrews, xiii, 16: "But to do good and to communicate, forget not, for with such sacrifices God is well pleased." Cicero says: "Nothing is greater proof of a narrow and groveling disposition than to be fond of riches; while nothing is more noble and exalted than to despise money if thou hast it not, and if thou hast it, employ it in acts of beneficence and liberality."

Such, ladies and gentlemen, were the characteristics of one of Ohio's great surgeons; one of those who made his mark in the history of medical literature; one who as much as any other helped to develop higher medical education in this Western country. He lived his well-rounded life as an example for the graduating class to look upon with pleasure, to follow with enthusiasm, and to emulate according to the best of their ability. He was one of those virtuous men who, in the annals of Western medical education, made his name immortal.

The distinguished surgeon whose life I have outlined died just before the opening of that vista upon the new field of bacteriology which has perhaps surpassed anesthesia in the wonderful changes it has wrought in the practice of surgery; and with anesthesia and bacteriology to its credit this nineteenth century will go down into history as leading all other centuries in the record of glorious achievements for the benefit of the human race and the relief of human suffering.

LECTURE.

RETROVERSIO UTERI AND PERIUTERINE INFLAMMATION.

Clinical lecture delivered at the Jefferson Hospital, Feb. 18, 1896.

BY E. E. MONTGOMERY, M.D.

PROFESSOR OF CLINICAL GYNECOLOGY IN THE JEFFERSON MEDICAL COLLEGE; GYNECOLOGIST TO JEFFERSON AND ST. JOSEPH'S HOSPITALS; PRESIDENT PHILADELPHIA OBSTETRICAL SOCIETY.
PHILADELPHIA, PA.

Gentlemen: This patient is 22 years of age, puberty occurred at 16, menses were regular, periods lasted four days and were without pain. She has been married four years and three years since had one child. The labor was normal. She had one abortion near the third month of gestation, two years ago. This abortion, owing to retention of the fetal envelope, was followed by pelvic inflammation. Since then she has

complained of dull, aching pain in the back and left side, aggravated at the menstrual periods. Micturition is normal. She has had no leucorrhea, appetite is fair, and the bowels are regular. On examination the uterus was found retroflexed, the body of the organ large, a certain amount of fixation upon the left side, and more or less tenderness. In this patient we have a history of suffering from puerperal inflammation of the uterus, and the inflammation has extended from that organ to the surrounding parts, particularly to the left ovary and tube. I have not been able, by superficial examination, to determine the relation of the ovary and tube, but the thickening and fixation leaves me in no doubt of their involvement. You will remember that we have said to you, inflammation may extend from the uterus in three ways: By continuity through the mucous membrane, thus reaching the peritoneal cavity; by the lymphatics, and by the blood vessels. The most frequent form, it is true, is that through the mucous membrane. These inflammations are always microbic in origin. The inflammation through the uterus, reaching the tube, gives rise to a salpingitis which may be simple in character, but if the infection be virulent, results in extensive inflammation and the formation of pus. Simple inflammation may lead to thickening of the mucous membrane, to desquamation of its ciliated columnar epithelium and to more or less obstruction of the canal of the oviduct. In such cases the passage of the fecundated ovum is arrested, and we have occurring what is known as an ectopic gestation. You can readily understand that where menstruation takes place every month, a Graafian follicle is ruptured, the ovum is thrown off, and hemorrhage takes place into the rupture, forming what is known as a corpus luteum. This corpus luteum in cases in which the individual becomes pregnant, is larger and is much slower in undergoing organization and contraction. Such a corpus luteum may afford a vulnerable point for the entrance of infection from the tube and lead to the development of an abscess in the ovary. Indeed, the corpus luteum may frequently afford an explanation of the occurrence of ovarian infection. I saw a patient a few years ago, in whom the ovary had become infected through the tube without any disease of the latter, and an ovarian abscess resulted which very seriously threatened the life of the patient. The muscular structure of the tube is arranged in longitudinal and circular fibers. Inflammation affects the action of these fibers, interference with the peristalsis, or obstruction of the caliber of the tube, increasing the predisposition to ectopic gestation. Some of you have recently seen a patient operated upon in this house, in whom rupture took place at the end of eight weeks, a large quantity of blood escaped into the peritoneal cavity and the life of the individual was thereby endangered. When we came to operate we found between one and two quarts of blood in the peritoneal cavity, which produced so marked an exsanguination of the patient that her life was despaired of. When the inflammation is limited to mucous membrane, it may be known as salpingitis or endosalpingitis. It is rarely, however, that we find it confined to the mucous membrane. The subjacent tissues, the muscular, and even the peritoneal tissue, become involved, producing perisalpingitis. These fine distinctions, however, have no special reference to the diagnosis or treatment, for we do not have one for a length of time without association of the other. The result of inflammation is to pro-

duce increased secretion and with decreased peristaltic action this secretion accumulates in the tube. This secretion may make its exit through the abdominal end of the tube into the peritoneal cavity, producing a sufficient amount of irritation to cause a localized inflammation. In some cases the patient has a slight peritoneal inflammation at each menstrual period as a result of this leakage. Where the fluid is particularly irritating, peritonitis is set up sufficient to occlude the end of the tube. The fimbriae become folded in and the peritoneal adhesions take place over the extremity of the tube, thus shutting it off and forming a sac. If the fimbriae are not entirely folded in, but project to a slight degree, opportunity is afforded for leakage and the occurrence of recurring attacks of peritoneal inflammation. With the closure of the abdominal end of the tube, the fluid is no longer able to escape into the peritoneal cavity and the thickening of the mucous membrane prevents its drainage into the uterus, consequently the tube becomes distended, forming a tumor. These tumors are designated hydrosalpinx when the fluid is serous, hematosalpinx when bloody, and pyosalpinx when purulent. The hydrosalpinx may arise from inflammation which is not so severe as to result in suppuration, or as sometimes is claimed, it results from changes which take place in an old pus sac. Hematosalpinx results from the rupture of blood vessels into the tube, and not unfrequently is the remnant of a tubal gestation. A patient who is suffering from an inflammation sufficient to engender tubal trouble, in which the entire mucous membrane is irritated, may have a simple inflammation transferred to a virulent through traumatism resulting from examination; thus, the introduction of the sound into an inflamed uterus without antiseptic precautions may produce a pyosalpinx. It is more likely, however, to occur as a result of septic infection following abortion, parturition, and not unfrequently as a result of infection from the gonococcus. We can not have an inflammation of the tube to any marked degree without the surrounding tissues become involved. Thus, a localized peritonitis results, in which the uterus, ovaries, tubes, and coils of intestine, are bound together, so that when the pelvis is opened we are at a loss to determine the relation of the organs, and how to proceed to separate them. Not unfrequently we find tubes and ovaries incapsulated, closely adherent to the rectum or other coil of the intestines. In tubal disease we have the ordinary symptoms of inflammation of the uterus which usually accompany it. The patient suffers from more or less nervous phenomena, pain at the menstrual period or during menstruation may result from disease of the pelvic organs. In tubal disease, however, the pain is situated in one or the other inguinal region. When this occurs prior to the menstruation we attribute it to a diseased condition of the ovaries. When it follows menstruation, it is undoubtedly due to disease of the tubes. Inflamed ovaries cause pain for a week or ten days prior to menstruation, due to the increased congestion of the organ as a result of the maturing Graafian follicle. That which occurs during the flow is usually uterine in character, but the tubal, as we have said, occurs after the cessation of the organ as a result of the menstruation and is probably due to the peristaltic efforts of the tube to empty itself of its contents. The symptoms will depend somewhat upon the extent of the disease. In those cases in which inflammation occurs and the ends of the tubes remain open,

the patient may suffer at each menstrual period or immediately following it, with a slight attack of pelvic peritonitis or pelvic irritation as indicated by increased pain in the region, tenderness over the abdomen and frequent evacuation of the urine. Where the tubes are closed an inflammation is more extensive, there is an accumulation of fluid, either blood, serum or pus, the symptoms become more marked, and here the pressure symptoms are especially determined. The adhesions become extensive, the abdomen is distended, the patient suffers from flatus. With inflammation which results in pus formation, there is variation in the temperature, elevation, sometimes depression. The temperature may be subnormal, but there is a variation between morning and evening temperature. In patients suffering from acute forms of disease, peritonitis is marked, causes tenderness over the abdomen, the limbs are drawn up, there is a frequent desire to evacuate the urine, evacuation of the bowels is painful and the patient suffers to such a degree as to demand immediate relief. After the more acute symptoms subside, she suffers from chronic symptoms. In internal suppuration we will have variation of temperature. In some cases there may be an increased discharge take place from the uterus; this may be periodical in character. The patient at times will be free from discharge; all at once there will be a gush of purulent or serous liquid which is simply due to drainage into the uterus through the uterine end of the tube. Where there is a mere watery accumulation the condition is known as hydrops tubae profluens, and indicates drainage of the sac through the uterus.

In such a case you may find a patient at one time presenting a mass of considerable size in one or the other broad ligament. At a later examination the same patient will disclose no sign of a tumor. The swelling has entirely disappeared. We may be at a loss to decide what has been the difficulty and may be led to suppose that you have formed an incorrect diagnosis. Upon inquiry you will find the patient has had a profuse watery discharge since her last examination. You recognize from this statement that you have had to deal with hydrops tubae profluens, and that later another accumulation will result. While we may infer the existence of pelvic inflammation from the symptoms the patient may make known to us, we are only able to arrive at a definite diagnosis by the physical signs. In an ordinary metritis which may cause pain and discharge, with irregular menstruation, the uterus and cervix are generally enlarged and situated at a lower level in the pelvis. In the cases in which inflammation involves the cellular tissue about the uterus, we recognize hardness or induration in the lateral fornices of the vagina and have to conclude as to the manner of treatment. Where the tubes are involved, becoming distended with secretion, increased in size and heavier than normal, they drop into the Douglas pouch, the lowest part of the pelvis, and upon examination of such a patient we find a club-shaped mass on either side of the uterus which decreases in size as we approach the uterus. This condition we recognize to be disease of the tube. Where the mass is movable, fluctuation is distinct and the history of the onset of the trouble has been gradual and without a distinctly marked history of inflammation, we may conclude we have to deal with hydrosalpinx. If the pelvic floor presents a hard, indurated condition, almost board-like in sensation, the patient has had an attack of pelvic peritonitis. Where the

inflammation has involved more particularly the ovary and tube, you are able to outline and definitely determine the masses situated on either side or posterior to the uterus, in which fluctuation may be distinctly determined. In cases which have gone on to suppuration, we generally find extensive adhesions to the surrounding viscera and pelvic tissues. The parts may be so matted together as to render us unable to accomplish the absolute extent of involvement, but we may be able to determine points of fluctuation in which there is more elasticity, showing the presence of fluid. You will ask how we are able to determine ovarian cyst from hydrosalpinx. The latter is generally more closely connected with the uterus; the former is spherical or globular in shape, while in hydrosalpinx the tumor is more club-shaped, irregular in outline and increases in size as you extend from the uterus. The smallest portion of the tube is near the uterus. In favorable cases we may be able to trace the tube and the mass to the uterus. The healthy Fallopian tube we are not generally able to recognize by palpation. In very thin abdominal walls we may be able to recognize a small cord in the upper part of the broad ligament, but whether it is the tube or round ligament may be sometimes difficult to determine. The treatment of salpingitis is exceedingly important. A few years ago every case of tubal disease would have been subjected to the knife. The mere fact that an individual has an inflammation of the tubes or ovaries was enough to indicate she must have her ovaries sacrificed, and if she had inflammation in one ovary or tube, the other must go also. Fortunately, however, for the human race, and for women generally, we do not feel it necessary simply because a woman is the victim of an inflammation which has extended through the uterus to the pelvis, that she should be at once subjected to operation. There are other procedures to which we should resort for the restoration of such cases. The important treatment in every case is prophylactic; treat the disease before inflammation has extended through the tubes and ovaries. When we recognize the danger in a case of inflammation of the uterus and pelvic organs, we endeavor to treat the patient in such a way as to limit the inflammation to the organ first affected. In cases of salpingitis we attempt to correct the disease or prevent its further extension and overcome the trouble by increasing or improving the uterine drainage. This we do by first dilating and curetting the organ, irrigating its cavity and packing it with iodoform gauze. The gauze through its capillary action acts as a drain and serves also to deplete the mucous membrane of the tube. Where the inflammation is more extensive, the condition may be a perisalpingitis. Here there is more or less binding down of the the organs, even though we may not be able to determine the presence of pus.

If the existence of suppuration can be eliminated, we may resort to pelvic massage, supplemented by hot douches, counter irritants and vaginal tampons of gauze and cotton saturated with some alterant in glycerin. In such a patient you would prohibit sexual relations, placing the patient sexually at rest, giving remedies that would promote her general nutrition and favor the more rapid absorption of exudation. Where the disease has gone on to suppuration and this can be determined through examination of the pelvis, is it necessary to resort to a sacrificial operation? Fortunately not; even in such cases, if we can determine accumulation of pus in the pelvis by making

examination through the vagina, we carefully cleanse the vaginal canal, make incision into the pus tract, irrigate it and pack the cavity with iodoform gauze. By such means we secure the obliteration of the sac which may involve either one or the other tube. The evacuation of the pus, irrigation of the cavity, packing with gauze, fills up with granulations and the focus of inflammation may thus be destroyed. After the removal of the pus, we have in such cases more or less fixation of the tubes, ovaries and pelvic organs. This may be corrected by massage treatment and the other measures suggested. Supposing however, we have a patient suffering from an acute attack of exudation about the uterus, in which a mass is felt to one side, but in which as yet suppuration has not occurred, for instance, a patient having an attack of inflammation following an abortion, a miscarriage or labor, or one who has had inflammation resulting from traumatism or following gonorrhea, the question confronts us as to what we shall do. If left, it may probably suppurate or become organized and form a hard, dense mass in the broad ligament, which will remain for a long period, interfering with the circulation. Formerly we would place such a patient in bed, keep her perfectly quiet, evacuate the bowels with salines, thus depleting the intestines, decreasing the amount of blood sent into the pelvic organs, and use aconite or veratrum viride, to limit the activity of the inflammation. This is good treatment, as far as it goes, but if the exudation is permitted to remain until it causes more or less contractions of the parts and formation of adhesions, it will be a long time before it is absorbed. If suppuration results there is extensive destruction of tissue so it will be possibly necessary to resort to sacrificial operation. In such cases the proper procedure would be to make an incision into the broad ligament, breaking up and affording a vent to the accumulation, packing it with iodoform gauze to secure drainage. The serous accumulation is thus evacuated and we may be able to accomplish in a week what would otherwise require years to obviate. So in such cases we would not only content ourselves with curettement and cleansing the uterine cavity, but would also open the tissue of the broad ligament on one or both sides if necessary, evacuate the inflammatory accumulation and drain. This may also be done in those cases in which we have extensive chronic inflammation, with large accumulation of pus thus enabling us to cure the patient without a sacrificial operation. Where pus exists on both sides of the abdomen, of such a character as to render it improbable we will be able to improve the health of the patient by its evacuation, it may be evacuated through the vagina, and after the patient has recovered from the more acute symptoms, a radical operation may be done. Where both sides are so involved that it will be necessary to sacrifice both ovaries, it is a question as to which shall be the direction by which the disease shall be attacked. Shall it be done through the abdomen or the vagina? This must depend somewhat upon the extent of the inflammation and whether, as we have have said, one or both organs is involved. If we definitely determine by examination that both organs are so involved the patient can only be relieved through their removal, the uterus is no longer an organ of value. Indeed, where the disease has extended from the uterus to the deeper structures, it is preferable that the former organ should be sacrificed as well as the ovaries and tubes, for if it is per-

mitted to remain, it becomes a source of trouble to the patient. The organ having been infected, inflammatory trouble having arisen in its walls, the resulting increase of the connective tissue subsequently contracting imprisons the nerves within its meshes, and causes pain and distress and increase of nervous phenomena from which the patient suffers. If we remove the uterus, ovaries and tubes, the operation can be done almost as readily through the vagina as through the abdomen, and this operation is preferable to the abdominal, owing to the sequelæ which may result from the latter. The probability of infection of the peritoneal cavity is decreased through evacuation of the pus through the vagina preliminary to opening the peritoneum. The adhesions of the intestines are less disturbed. These adhesions have been of such a character as not to interfere with the evacuation of the bowels. If they are broken up, the new adhesions forming may not be so favorable. The drainage is from the most dependent portion of the pelvis and affords an excellent outlet. We obviate the abdominal incision and the danger of subsequent ventral hernia. The convalescence is shorter, is free from the retention within the pelvis of sutures or ligatures which may become infected and be the cause of a sinus which will remain until they are discharged. In cases, however, in which the pus tube is situated upon one side, in which we hope by the sacrifice of one tube and ovary to save the other, the preferable procedure should be through the abdomen. It is true that we may do what is known as an anterior colpotomy, making an incision through the anterior vaginal wall between the uterus and bladder. The fundus of the uterus is tilted forward and brought out, following it with the tube and ovary on either side. The diseased mass may be removed, the uterus then fastened against the bladder and anterior vaginal wall. In some cases where the mass is situated so it can be readily reached, it may be evacuated and drained through the vagina without the necessity of a sacrificial operation.

ORIGINAL ARTICLES.

NAPOLEON'S ALLEGED EPILEPSY.

BY EDMUND ANDREWS, M.D., LL.D.

SENIOR SURGEON OF MERCY HOSPITAL,
CHICAGO.

In the JOURNAL of Dec. 22, 1895, I gave an account of Napoleon's diseases, including his rumored epilepsy. Since writing that article I have received from Europe some additional facts and statements, largely through the courtesy of Dr. Robert Harvey, of Chicago, temporarily residing in Vienna, who collected for me whatever could be found in that city bearing on the disputed question of Bonaparte's epilepsy. I am also under obligations to Dr. A. Lagorio, of Chicago, for assistance in examining Italian literature. The main facts and statements brought forward to prove the epileptic attacks are as follows, taking them in chronological order:

M. de Norwins, in his *Histoire de Napoleon*, Paris, 1838, Vol. I, p. 11, says that when the young Napoleon was in the military school, a mere boy, he broke the rules and was subjected to a very humiliating punishment. The effect was to bring on a violent nervous disturbance, so alarming that the punishment was discontinued by his superior officer. This vague description is totally insufficient to establish a diagnosis of epilepsy, and may be dismissed.

After attaining imperial power we find, as early as 1804, a rumor, credited even by some members of his court, that he was subject to epilepsy. In that year a court lady, whose name is concealed, possibly Madame de Remusat, kept a diary of the emperor's journey to Magonza. She states that on September 10 Napoleon "suffered from his nervous complaint or epilepsy, to which he was subject." She adds that Josephine called assistance, and that "after many hours of suffering the attack was calmed." This extract from the anonymous diary is inserted in the *Memoirs of Napoleon* by Constant, the chief valet de chambre. Constant appears to have been a faithful and honest writer. Whether the authoress of the diary was so we do not know. She rather vaguely calls the attack "his nervous complaint, or epilepsy," but the statement that it was calmed "after many hours of suffering" does not correctly describe a true epilepsy. The emperor forbade Josephine to speak of it.

On another occasion the chief valet, Constant, says he heard distressing sounds and complaints coming from the imperial chamber. Going in he found Napoleon lying on his bed with his mouth wide open, from which issued inarticulate sounds, while one hand was clasped upon his stomach. Constant with some difficulty aroused him, and the emperor asked, "What is the matter?" He then related a terrible dream in which he thought a bear was sitting on his chest and trying to eat out his heart. Epileptics do not lie with the mouth open. The description of Constant indicates a severe attack of nightmare, or incubus.

Baron de Talleyrand, the emperor's minister of foreign affairs, asserts that he and Count de Remusat, the chief chamberlain, witnessed together one of his attacks. The Baron states that he accompanied his majesty on a journey to Strassburg. That on one occasion Napoleon entered Josephine's chamber, but came hastily out again, seized Talleyrand by the arm, drew him into an adjacent room and confusedly ordered the door to be shut. He then fell like a dead body and had contortions which Talleyrand describes as follows: "He groaned, frothed at the mouth (*il gémissait et bavait*), he rolled and rubbed, and had some sort of convulsions, which ceased in about a quarter of an hour. A little afterward he began to speak, and came to himself. He ordered us to be silent, and in half an hour was on the road to Carlsruhe."

This is as good a description of true epilepsy as a non-professional man could be expected to make, except the phrase "he rolled," a motion which seldom occurs in epilepsy. This, however, might be the inadvertent error of an excited observer. On the whole, if Talleyrand did not misrepresent, it was a true epileptic seizure. On the other hand, we must remember that the emperor and Talleyrand came gradually to hate each other with the greatest intensity, though the pressure of political necessity and the possession of too many state and Napoleonic secrets between them compelled the two men to continue to act in concert.

Talleyrand, like most of the diplomats of Europe at that time, was a colossal fabricator of incorrect statements, and his keen enmity toward the emperor may have led him in his later years to take a hint from the current rumors of epilepsy, and give them the support of a definite but fictitious story.

In 1810 an Englishman named Goldsmith published

a book filled with all sorts of stories against Bonaparte. Among them he related that a Parisian actress claimed that she had been called to spend the night with Napoleon at the palace of St. Cloud, and that while there he had a violent attack of convulsions. She was so frightened that she screamed aloud and roused the attendants, etc.

This might possibly be true, but prostitutes are constantly making false statements about their adventures with great men. Their testimony is usually a lie and is worth nothing as proof of any alleged fact.

The above accounts comprise about all the contemporary testimony in support of the idea that Napoleon was an epileptic. None of them are decisive, yet taken together they give some weight to the supposition.

The proofs on the opposite side of the question are the following:

1. Of the numerous medical men who at various times had attended the emperor and his family there were six who, by direct or indirect permission, felt at liberty to publish what they observed of his diseases. Four of these were intimate with him at St. Helena. The six were Warder, O'Meara, Antommarchi, Arnott, Héreau and Carvisart. These men left in their writings not a word on the subject of the epilepsy. Héreau alone, who examined the writings of all the others, and drew up a report for the information of the emperor's son, appends a remark which seems indirectly to be intended for a reply to the public rumors. He assures the young Napoleon that his father had no disease which tended in the least to obscure the splendor of his intellectual powers.

2. M. Constant, chief valet de chambre, lived in the closest intimacy with the emperor for the greater part of his public life. After his master's death he published copious memoirs, drawn up with the utmost truth and faithfulness. He mentions some of the stories about epilepsy, but says positively, "The emperor was never a subject of epileptic attacks." Professor Teobaldi, of the University of Padua, in a recent treatise on Napoleon, after quoting Constant's assertion adds, as the result of his studies: "Nobody ever saw him fall from his horse, or interrupt a conversation, or suffer any convulsive attack in public. He was not found epileptic by his physicians."

3. "Napoleon's private secretary, De Bourrienne, after the emperor's death published copious memoirs. He says, in Vol. I, p. 278, English edition, as follows: 'It has been said over and over again that he (Napoleon) was subject to repeated attacks of epilepsy, but during the eleven years that I was almost constantly with him, I never observed any symptom which in the least degree denoted that malady.' De Bourrienne was dismissed from the imperial service in disgrace under charges of peculation, and forced to refund one million francs to the treasury. He is said to have cherished great animosity to the emperor ever after, so that he would not be likely to deny the story of epilepsy, if there had been any truth in it."

On the whole, I conclude that the witnesses denying the epilepsy are more credible than those asserting it, but the emperor had an ungovernable temper and a very excitable nervous system, which in some cases carried him into semi-hysterical manifestations, but not into true classical epilepsy. Professor Teobaldi, of Padua, after examining the evidence, comes to nearly the same conclusion.

2520 Prairie Avenue, Chicago.

FRACTURE OF THE FOREARM COMPLICATED WITH DISLOCATION.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY E. GRISWOLD, M.D.

SURGEON ERIE RAILWAY,
SHARON, PA.

The mechanism of the human hand, with its great variety of movements and its marvelous adaptability to the purposes for which it is intended, furnishes a strong evidence against the doctrine of those who have doubt as to the origin of man. The best productions of artificial hands, by the highest development of human art yet made, have fallen far short of the natural member, in a mechanical sense, and it is only in that sense that any artificial approximation can be made. The vital principle, emanating from the brain and spine is necessary to the perfection of this organ, and as much as the man, the mechanic or the artist resembles his Creator, he is still unable to control that vital principle, as against natural physiologic activities, and these activities are maintained by the forearm, which may be said to be the dynamo of the hand, and whenever from any cause this organ is injured so that the normal action of its muscles is impaired the movements of the hands are more or less curtailed. The skeletal structure of the forearm, consisting of the radius and ulna, is so constructed that it has a wide range of motion, not the least important of which is its rotation, which extends beyond a semicircle. When the hand is fully supinated these bones lie nearly parallel with each other, when pronated the radius lies in an oblique direction, across the shaft of the ulna with its articular carpal end on the inner side instead of on the outer side of the ulna, as it is in supination. The radius attached to the outer condyle of the humerus above, by a slightly concave surface, and to the outer surface of the olecranon process of the ulna by the coronary ligament, which gives it free rotary motion, is chiefly concerned in these acts of supination and pronation. The head of the radius constitutes but a small portion of the bulk of the large joint, of which it forms a part, but if measured by its functions we must admit that it is of considerable importance. At its carpal end we find it articulates with the three principal bones of the first row of the carpus, namely, the scaphoid, semilunar and cuneiform, and practically forms the whole of the wrist joint. The ulna performs only a minor part, and does not enter into the formation of the joint. This bone, with its little head and big base, controls for the most part the actions of the hand, while the brachialis in front reinforces the power of the biceps flexor cubiti, which is attached to the tubercle of the radius and flexes the forearm. The large size and complicated form of the ulna at the elbow joint, with its greater sigmoid fossa fitted to the inner condyle of the humerus, its lesser sigmoid fossa fitted to the head of the radius, its coronoid process which forms the inferior boundary of the greater fossa, and its muscular attachments and powerful ligamentous involucrum, all combine to place it in strong contrast, both in structure and function, to its carpal end. Of the twenty muscles of these two bones, five are attached to the inner condyle of the humerus, and act as flexors and pronators of the fingers, wrist and hand. Three of the deep layer, lying beneath these, originate from these two bones below the condyles. Of these, two, the flexor longus pollicis and the flexor profundus

digitorum, as their names imply, are flexors, pure and simple, and one, the pronator quadratus, is purely a rotator. In the radial region or border, we have three muscles all arising from the external condyle and the external condyloid ridge of the humerus. One of these is attached to the styloid process of the radius and therefore acts as a supinator, the other two acting as extensors of the hand. There are nine muscles on the back or dorsal aspect of the forearm. These, the muscles of the radial and posterior brachial regions, comprise all the extensor and supinator muscles and act on the forearm, hand and wrist. They are the direct antagonists of the pronators and flexors. The anconeus assists the triceps in extending the forearm. The supinator longus and brevis are the supinators of the forearm and hand, and the former acts as a flexor if its action is continued after supination is complete. The extensor carpi radialis longior and brevior and the extensor carpi ulnaris muscles are the extensors of the wrist, and continuing their action, serve to extend the forearm upon the arm. They are the direct antagonists of the flexor carpi radialis and ulnaris. The bones of the forearm, when extended and fully pronated are nearly in line with the long axis of the humerus, but when fully supinated the forearm represents a divergence of about 10 degrees outward. Neither the elbow nor the wrist joints are at right angles with the long axis of the humerus or the bones of the forearm. That at the elbow slanting toward the inner condyle, bringing the trochlea for the great scaphoid fossa of the olecranon at a lower level than the articular surface for the radial head, while the styloid process of the radius extends lower in supination than that of the ulna. These data have some importance when attempting to make a differential diagnoses as between fractures and dislocations. The blood and nerve supply of the forearm and hand are ample in the normal state, but lesions of these vessels and nerves in cases of fracture, especially so in crushed fractures, have much to do with the results of treatment; for large destruction of muscles may be present without serious functional impairment if the blood vessels and nerves are but slightly injured, or not injured at all. As regards the nerve supply, if we know the distribution and the degree of injury the nerves have sustained, we may judge pretty well as to the probability of paresis or paralysis supervening. The distribution of the median, ulnar and musculospiral, the latter mainly by its radial branch, while not exactly uniform in all subjects, is sufficiently so for all practical surgical purposes. These incomplete anatomic data of the forearm may be helpful in the diagnosis of its fractures and dislocations. Fractures of the forearm are of frequent occurrence, especially those involving the lower end of the radius. Sometimes they only involve a portion of the articular surface of the radius, sometimes the articular surface is badly fissured and the fracture extends some distance up the shaft. There is an occasional separation of the apophyses in young subjects, and impactions are not infrequent. The deformities caused by most of these fractures, especially in Colles fractures, is no doubt largely due to the force which produces them. This is usually a fall on the palm of the hand, the weight of the body acting through the limb with sledge-hammer force so that the fractured lower end of the radius is driven upward beneath the supinator and extensor tendons and is pretty firmly held there, not so much probably by the contraction of these muscles

as by the binding power of their tendons. If the force of the fall has been very great, so as to cause considerable displacement, the ulna is almost certain to be either dislocated or fractured. If a Moore's dislocation is the result, this may greatly add to the difficulties of the treatment. The intervention of blood clots or other tissues and agencies sometimes render complete coaptation difficult if not impracticable and when it is successfully attained the spasmodic action of the muscles often render it impossible to maintain it. Dr. E. M. Moore's demonstrations of the dislocation and occasional fracture of the head of the ulna as an accompaniment of fractures of the lower end of the radius seem to have attracted less attention than they deserve. Several cases of this kind have fallen under my observation and a still larger number in which there appeared to be a partial dislocation of the head of the ulna. Dr. Moore met with several cases in which there was dislocation of the head of the ulna accompanying fracture of the carpal end of the radius, and in which the ulna was driven into, or partly under the annular ligament. This malposition rendered coaptation of the fragments of the radius impossible until the imprisoned head of the ulna had been liberated. If the fracture of the radius is not completely reduced and a shortening results the obliquity of the radio-carpal articulation is increased, the radius shortened and the head of the ulna rendered more prominent, causing a conspicuous deformity. This deformity may also happen, but generally in a less degree, if the radius is fractured higher up, and reduction and coaptation have not been perfect during the period of bony union. Separation of the apophysis may cause a good deal of deformity and be easily mistaken for a dislocation, but occurring as it always does in young subjects in whom muscular rigidity is generally inconsiderable, reduction is generally easy and the crepitus is differential. Gunshot fractures of the carpal end of the radius sometimes happen without much displacement. The cancellous structure of this end of the bone with its thinned outer layer of hard tissue makes it quite possible for a small solid shot to perforate it without causing much splitting, splintering or bone displacement. It is, of course, quite different when the radius is shattered by a charge of finer shot. The ordinary causes of fractures of the lower end of the radius are liable to be in operation in railroad and machinery accidents, but in these latter accidents we are more likely to find the soft parts crushed and so badly injured as to be devitalized. Fractures of the shaft of the ulna, unless caused by direct force, are not infrequently complicated with dislocation of the head of the radius. This is more apt to be the case if the fracture has been produced by falling on the partially extended palm of the hand as in most cases of fracture of the lower end of the radius. The shaft of the radius being in these accidents too strong to yield, and the force being great, the ligaments of the head of the radius give way and it is forced upward on the anterior surface of the external condyle of the humerus.

Fracture of the coronoid process of the ulna is very rare, except as a complication of dislocation of the ulna backward. The tendency to muscular displacement, in this little fracture, is inconsiderable as the only muscle attached to it is the brachialis anticus, and its fibers are so spread out on and over the ulna below, that very little traction on the fragment can occur unless these fibers are torn by the injury. This process is so small that it is not always easy to determine

when it is fractured, especially when the swelling has become considerable before examination. It may, however, occasionally be felt as a small movable body under the skin of the part by careful manipulation. Fracture of the head or neck of the radius is more frequently met with in connection with dislocation of the olecranon accompanied by fracture of the coronoid process than otherwise. This too is sometimes of difficult diagnosis, but when there is not too much swelling the lesion can generally be distinguished by the pain or tenderness, or sometimes by the crepitus and pain on supination and by the evident want of motion of the head when rotating, or by attempting extension or shortening of the shaft of the radius. If there be fracture of the external condyle with the fracture of the head or neck of the radius the latter may easily be overlooked. A fracture of the radius between the insertion of the biceps and the pronator radii teres is liable to result in a bad cure unless the situation of the fracture and its anatomic relations are appreciated and the action of the biceps on the upper fragment, and the pronator quadratus on the lower are antagonized. This biceps being attached to the back part of the bicipital tuberosity rotates the upper fragment outward and produces more or less complete supination, while the pronator quadratus pulls the lower fragment in the opposite direction toward the ulna and produces pronation. Now, if these displacements be real, it is easy to see that even if the ends of the bone are brought into line and osseous union effected, the limb will be sadly defective, unless the supination of the upper fragment and pronation of the lower can be corrected. Consolidation would, in this condition of the parts, result in almost complete loss of pronation and supination, but relaxation of the tendon of the biceps by a rectangular position of the forearm together with manipulation of the two fragments, would rotate, the one outward and the other inward and bring their normal transverse axes to correspond with each other. This fracture should then be dressed with a rectangular splint.

It begins to appear that my subject is too large to admit of full and specialized consideration in detail within time limits, and so, after giving a short history of a private case and then some statistic facts, with a few comments on shot fractures of the forearm my time will have been fully occupied.

John L. Allen, a fair-haired, light complexioned boy, aged 15, accidentally discharged a heavy load of shot into the ulnar side of the right arm in June, 1883. The ulna was broken from about the junction of its middle and lower thirds to near the coronoid process and the muscular structures largely carried away. The flexor and pronators and portions of the extensors were nearly destroyed, close up to the joint, a considerable portion of the interosseous, together with the ulnar artery and nerve were also destroyed. He nearly bled to death before he got assistance. The artery was tied at both ends, the ulna cut off smooth at both ends, and the loose fragments removed leaving a hiatus of four inches in its continuity. The arm was dressed with lint and put on a pillow covered with oil silk and a syphon supplied with cold water made to play on it day and night continually. There was no inflammation or suppuration. It granulated and closed in a few weeks without incident. He obtained a business education and is a book-keeper. The little finger and the ring finger are flexed in a state of permanent contracture. The other fingers and

the thumb have a large range of motion, and he says the arm is strong. The median and radial nerves were not much injured. The usefulness of this arm furnishes a striking contrast with the conditions of most of those who suffered similar or even less mutilation in military practice. The following statistics are from the Surgical History of our Civil War, Vol. 11, beginning at page 921.

There were thirty-two cases of injuries to the bones of the forearm classified as partial fractures. They were not cases of solution of continuity but were chipped or grooved by the passage of balls across their surface. They involved the ulna in twelve cases, the radius in fifteen, both bones in one, and four were not specified. Twenty-eight of these cases were treated conservatively and of these two died. The other four were amputated in the upper arm and two of these died. So that the mortality of these thirty-two cases of partial fracture was 12.5 per cent., a larger percentage than followed in the treatment of cases of complicated fractures of these bones. In military practice the larger share of fractures of the bones of the forearm are in the ulna, the radius being next in number and both bones third. There is a complete record of 5,194 cases of shot fracture of the bones of the forearm. About three-fifths of these cases were treated without operative interference with a mortality of 6.4 per cent. The radius and ulna were both fractured in 1,291 cases or a little less than one-third of the whole number of cases in which the seat of the fracture was specified. This group as might be expected contains a larger number of cases requiring operative interference than the others in which a single bone only was involved; 323 of these 1,291 cases were treated conservatively and there were 299 recoveries, 103 of whom returned to modified duty and 196 were discharged. These recoveries were left with more or less disabled limbs, very few of them having much rotation left. Pseudoarthrosis occurred in two cases. The death rate was 7.4 per cent.

Fractures of the Ulna treated Conservatively.—The results here in 1,044 cases, all but 5 of which were determined, were recoveries 980, deaths 59, a mortality 5.6 per cent. Of these 980 recoveries, 490 returned to modified duty and 490 were discharged. Eighteen of these recoveries had secondary hemorrhages. In three, ligature of the brachial, in five, ligature of the ulnar and in four, ligature of the radial was practiced. The other six recovered under the use of styptics and compression without ligature.

Of the 59 deaths out of the 1,039 determined cases of shot fracture of the ulna the greater number were caused by pyemia and gangrene. Of 999 shot fractures of the radius treated during the war the proportion of deaths is rather less than resulted from fracture of the ulna, but the degree of disability is greater. Of the 949 of these cases that recovered 445 returned to modified duty and 504 were discharged—a considerably larger proportion than was discharged among those recovered from fractures of the ulna. Quite a number of the recovered cases had secondary hemorrhage requiring the ligature, a few had hospital gangrene, a few erysipelas, and many had osteitis, necrosis and exfoliation of bone. In some instances long cylindrical sequestra were removed. There were 147 cases among the recoveries in which considerable sequestra were removed. Of the fifty fatal cases in this series five died of pyemia, in six secondary hemorrhage caused death, two died of tetanus, one from gangrene

and two of erysipelatous complications, but the majority of the deaths were reported from exhaustion and from the various affections arising during their hospital residence. Hospitalism was then an important factor in results. In aggregation out of the 5,194 cases of shot fractures of the forearm 2,970 were treated conservatively. The graver complications among these were comparatively infrequent. There were, however, twenty-seven deaths from pyemia, four from tetanus, thirteen from secondary hemorrhage. There were fifty-seven cases of severe secondary hemorrhages treated out of this large series requiring in different cases ligation of the brachial, radial, ulnar and interosseous arteries.

Excisions in the continuity of the bones of the forearm were practiced in 986 out of the 5,194 cases of shot injuries of the forearm, with a mortality of 11.2 per cent.; 496 of these excisions were of the ulna, 413 of the radius and 59 of portions of the shafts of both bones; 18 cases were not specified as to the bone or part of it that was excised. Excisions were classified as primary when done before swelling or inflammation occurred, or in general within thirty-six to forty-eight hours from date of injury; intermediate when done later, or within twenty to thirty days, and secondary when done after thirty days. Primary excision of one or both bones was done in 665 of the cases with a mortality of 71,—10.6 per cent. Five of the cases were undetermined. The excision involved the ulna in 321 cases, the radius in 291, both bones in 40 and in 13 the seat of the excision was not specified. Forty-four of these cases were Confederate soldiers.

Of the forty excisions of both bones, thirty-four were successful as regards the saving of life, but eighteen of them afterward required amputation, and among the twenty-two who retained their arms not a single good result was obtained. In fact the recovered cases who retained their limbs were worse off than if amputation had been done as the limbs were useless appendages and a hindrance. Excision of the shaft of the ulna shows 290 recoveries. The length of the shaft removed varied from one to six inches, in one case the entire diaphysis was removed. In one of this series excision was made in the radius of the right arm and the ulna of the left. This man died in 1872 and a short time before his death pension examiner, O. M. Stockwell, of Port Huron, Mich., reported his "disability is almost equivalent to the loss of both hands" and in general the ulterior pension reports in these cases show a disappointment in regard to the expected usefulness of the limbs. Of 413 primary excisions of the shaft of the radius 256 recovered.

Table 126 gives 589 cases of recovery after primary excisions of the bones of the forearm for shot wounds (36 were Confederate) of which 147 were returned to modified duty and 406 discharged from the service.

Intermediary Excisions of the Bones of the Forearm.—Of these 149 cases with a mortality of 19.4 per cent., or 29 deaths are reported; 9 cases involving both bones, 64 the ulna and 47 the radius. Among the 120 cases of recovery after intermediary excision of the forearm were eleven of secondary hemorrhage, three consecutive amputations in the forearm and six in the upper arm. Of the twenty-nine deaths of this series the greater number were from pyemia and pyemic complications. None of these were done on both arms, eighteen were of the ulna and eleven of the radius. Unsuccessful consecutive amputations were

done in the upper arm in five cases. The fatal issue in one of them was thought to be due to the concomitant fracture of the spinous process of one of the dorsal vertebrae. There were forty secondary excisions made after thirty days from date of injury. Seven of these involved the shaft of both bones, twenty-one of the ulna only, and eleven of the radius and one not specified. There were four fatal cases of these secondary operations. Beside the different series of cases above shown in which a classification as to date of operation was given, there were 132 cases of excision of the forearm not classified, in which the small mortality rate of 4.3 per cent. was reported.

RECAPITULATION IN AGGREGATE.

This large number of excisions, 2,251, of the bones of the forearm compares unfavorably in results with the larger number, 2,943 treated on conservative principles, both as regards mortality and subsequent usefulness of the limbs. Could aseptic, or even antiseptic surgery be made available in future wars, the results would no doubt be improved, and resection and amputation would be found unnecessary in a large portion of cases in which they were practiced in preantiseptic times.

The mortality 2,943 cases of shot fracture of the forearm treated by conservatism was 6.4 per cent. and of the 965 treated by excision 11.2 per cent. and of 1,256 treated by amputation primarily or consecutively performed, the death rate was 16.3.

In studying these statistical results we note with interest if not surprise the great difference in the mortality of cases treated conservatively and those treated by excision or amputation. The fact, however, is not to be overlooked that the milder cases were as a rule treated conservatively and the more severe by excision or primary or conservative amputation. Unless antiseptic surgery can improve the results of excision of the bones of the forearm the operation ought to be abandoned in military practice and the same remark may apply equally to railroad surgery.

AN UNUSUAL CASE OF FRACTURE OF THE SKULL.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY F. H. PECK, M.D.

SURGEON, N. Y., O. & W. RY., UTICA, N. Y.

I have to beg the indulgence of the Academy for bringing up in a very new and crude way a history of a case which has always been extremely interesting to me, and I will explain how it is that I am unable to give more complete data of the case. It is a case of fracture of the skull which occurred during my service at the State Emigrant Hospital, New York, when that institution was located upon Ward's Island and under the government of the New York commissioners of immigration. Some three or four years following my service the department was taken out of the hands of the New York State commissioners of immigration and put into the hands of a single-headed commission which was under the general government, and the hospital was removed from Ward's Island to Ellis Island in the harbor so that my data in regard to the case are rendered inaccessible. It is a case I should have reported at the time it occurred, excepting that I was very young in the profession and thought that it would be rather presumptuous for one who was but a recent graduate to rush into print. My

only apology for now presenting it is that the case is interesting to show the amount of injury which the skull and its contents will occasionally tolerate, not on account of good treatment, but perhaps in spite of the treatment, and the fact that the case has never been presented before.

In the summer of 1882 an Italian, about thirty years of age, belonging to a construction gang on the West Shore Railway, then being built, was admitted to my service in the state Emigrant Hospital, New York, with a compound fracture of the bones of the skull, and with the following history, partly obtained from the Chambers Street Hospital, and partly from the patient after his restoration to complete consciousness: Three days prior to coming under my care, while at work in a rock-cutting, he was instructed to dig out a blast which had failed to explode, with the result that the heavy charge exploded in his face. He was taken across the river to Chambers Street Hospital, and on the third day transferred to the State Emigrant Hospital, on account of the development of erysipelas in the margins of the wound, as no septic cases were allowed to remain in the Chambers Street wards.

Physical signs on admission were as follows: A compound fracture of the frontal bone extending transversely across the forehead just above the frontal eminences and below the hairy margin of the scalp. The wound through the soft tissues was about five and one half inches in length and gaping to about one and one half inches at its widest part; extending from a point about two inches superior to the right external angular process to a point about equally distant above the middle of the left superciliary ridge, and communicating freely with the cranial cavity and brain through the subjacent fracture and an equally large laceration through the meninges. The cutaneous surface surrounding the wound for a distance of about an inch from its margins was swollen and reddened with an angry erysipelatous blush. The bottom of the wound was filled with detritus composed of necrosed brain tissue, small fragments of rock and some loose bony fragments. The fracture could be traced beyond the limit of the open wound to the left external angular process; thence it extended through the roof of the left orbit, emerging in the nasal bones which it traversed obliquely downward, through the right malar bone, and thence outward and upward to its point of origin near the superior extremity of the right temporal ridge of the frontal bone. It extended across the base of the anterior portion of the skull from the left external angular process through the left orbital plate of the frontal bone, and posterior to and including the right orbit, or the greater part of it, to a point on the external aspect of the right great wing of the sphenoid, including in the parts fractured from the rest of the cranium nearly all of the frontal and ethmoid, and portions of the sphenoid, nasal and right malar bones. This was proven by the mobility of the portion fractured off, which was so mobile as to move back and forth with every cardiac impulse transmitted through the cranial pulsations, and by the fact that the upper right portion of the face, including the right orbit and globe of the eye, was advanced anterior to the plane of the upper left portion of the face and left eye. This obliquity of the frontal structures and eyes remained after the wound was healed, the right eye being about five eighths of an inch anterior to the plane of its fellow, and the facial deformity was well shown in a tin-type which he brought me, but

which I unfortunately left at the hospital at the end of my term of service.

The patient was in a condition of mild stuporous delirium, answering questions when aroused, but irrationally and *mal à propos*. Through loss of notes I am unable to give clinical record of pulse and temperature.

Confronted with the above conditions I considered his injuries necessarily fatal, and believing I could do no harm in contributing to the fatal issue, I was extremely bold in exploring and cleaning out the wound in the cranial cavity, introducing all the fingers of my hand into the cranium so that in the manipulation the anterior portion of the right anterior lobe of the brain rested in my hand on the palmar surface of the fingers. In this manner, and assisted by irrigation I removed the detritus, including, I should think, as much as half an ounce of softened and detached brain substance. The selection of dressing next perplexed me. You will remember this was in 1882 in the early days of antiseptis, and the only agents then in use to modify septic conditions were carbolic acid and iodoform, neither of which I wished to apply to a wound communicating so freely with the brain on account of their irritant properties. I contented myself with applying compresses kept constantly saturated with cold water, and to my surprise the patient immediately and steadily improved; the erysipelatous redness, fever and delirium disappeared within a week or ten days; the wound granulated and cicatrized from the edges, and he progressed to an uneventful recovery, and was discharged cured about two months after his admission to the hospital. After his delirium subsided he showed no impairment of mental powers nor loss of function save the sense of smell, which was completely lost through rupture of the olfactory filaments.

On his discharge I asked him to report after the lapse of two or three months that I might further examine as to his cerebral functions, and at the end of two months he presented himself again bringing a picture showing his facial deformity as stated above, and showing no mental deterioration.

DISCUSSION.

DR. DALBY—The paper just read and case cited by Dr. Peck—skull fractures and to what extent these fractures may go and still the patient recover—simply adds another to the already long list. We have seen compound fractures in such aggravated shapes that seemed as though recovery would simply be impossible. As he stated in the paper, in this case he got well in spite of any medical attention; I think a great many of them do. In cases of fractured skull as they come under the railway surgeon's attention, beyond cleansing the wound and making it as aseptic as possible, relieving the pressure, is about as much as we can do. The case he cites is certainly an interesting one, but, as I stated, only another of a long list of these horrible fractures where patients recover in spite of all we may do and may not do. As I have stated, there is very little in such cases that can be done anyhow, even in the surgical field. After we have made the wound aseptic and relieved the pressure we have performed about all the surgeon can do.

Valerianate of Antipyrin. A writer in the *Boston Medical and Surgical Journal* recommends that the following formula be used to prepare this salt. It has been used in cases of nervous prostration with recurrent hysterical symptoms: Antipyrin, grs. xxviii; aq. destillat. q. s. ad ft. sol.; ft. sol. et adde acidi valerianici, gtt. xv. Mince. Shake well, and stand aside to allow the salt to crystallize.

THE USE OF GOLD FOIL IN FRACTURES OF THE CRANIUM AND RESULTING HERNIA CEREBRI.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY W. L. ESTES, M.D.

CHIEF SURGEON, L. V. RY., SO. BETHLEHEM, PA.

The three cases related in this paper are offered as illustrations of a slight advance in hetero-plastic attempts, and are unique in that they were done on the contents of the cranium, and not on the cranial walls themselves. The nearest approach I have found to the attempts I have made were by Weir, of New York, and to his pioneer work in using gold foil to prevent adhesion of the dura to the cranial bones after serious fractures and removal of pieces of bone from the cranium, I have extended the use of the foil in one case to plug up the cavity in the cerebrum itself, and in two other cases to replace destroyed dura—not with the idea or indication of preventing adhesion but of replacing the obturator function of the lost membrane, and so prevent a further escape of cerebral tissue and subsequent development of a hernia cerebri.

The number of cases is too small to serve as an authoritative guide for future routine practice; these cases indicate, however, beyond the shadow of doubt the extreme tolerance of the brain and cranial contents to foreign bodies and may encourage further attempts in even more radical directions. For instance, it happened once to me in operating on the cerebrum to open the lateral ventricle, and I found no ordinary plug nor suturing nor compression would prevent the constant escape of cerebro-spinal fluid, which finally caused the death of the patient. Having the experience of these cases in mind I should not now hesitate to form a new roof for the lateral ventricle by gold, or if need be plug its cavity with a cup of gold. The gold foil might also be useful in controlling the escape of cerebral tissue or help fill the cavity left after removal of tumors from the brain, and so on. It must be understood that this kind of hetero-plasty demands the strictest aseptic technique and most careful attention to details.

A most valuable adjunct to the specific use of the gold foil inside the cranium, is the inhibitory action it exerts against the growth and development of the microorganisms. This most beneficent quality was discovered at Johns Hopkins Hospital by Drs. Welsh and Halstead. It is true also of silver foil and metal plates and sutures generally which will resist the corroding actions of the animal tissue and fluids. This inhibitory action against microorganisms may explain the removable aseptic course of the second and third cases, after the use of gold foil when the conditions previous to the operation were particularly favorable to subsequent suppuration.

The gold foil I have used has been next to the thickest foil ordinarily used in dentistry, I sterilized it by a prolonged immersion in a 5 per cent. solution of carbolic acid and just before using it washed it thoroughly in a sterilized normal saline solution. During the operation a warm sterilized saline solution was used for all purposes of douching or washing about the wound or within the cranium. I invariably prefer to remove by gentle douching any detached cerebral matter, clots, or debris from the cranial cavity, rather than by swabbing with any sort of gauze or

sponge. I have found capillary drainage quite sufficient in these cases. I have used stout catgut, or a narrow piece of sterilized iodoformized gauze as drains.

The arguments specially in favor of these hetero-plastic attempts, rather than autoplasty, are two-fold. 1. After a stock of gold foil has been obtained it is always ready and is easily employed, whereas autoplasty, after complete destruction of an area of dura or cerebrum, is extremely difficult and usually indeed impracticable. 2. Hetero-plasty introduces a substance which if it prove an irritant does so simply by its presence as a mechanical result, so to speak, and it acts as an efficient inhibitor of microgenesis, whereas autoplasty may, and commonly does, result in necrobiosis and infection of the already badly injured tissues. The former may be removed *in toto* without much disturbance and with relief to the symptoms, whereas in the latter case the result of the death of the organic graft is usually irreparable and far reaching.

The cases are as follows (The first case was published a few months ago in the *Medical News*. The other two cases are given here for the first time):

Case 1. Cornelius B., a negro, 28 years of age, was brought to the hospital in an unconscious condition on the night of April 4, 1893. The ambulance surgeon was told that while the patient with a companion was out driving, Cornelius, by what means or agency could not be discovered, was thrown to the ground and kicked by the horse, becoming immediately unconscious. He was forthwith taken in charge by his companion and sent by railroad a distance of some twenty-odd miles, and finally was received at the hospital, still unconscious, three or four hours after the injury. No dressing or covering of any sort had been placed over the wound. Examination showed no injury anywhere, not even an apparent bruise, except on the right side of his head, where there was a *punched-out* sort of wound through the scalp and bone and deep into the cranial cavity. The location of this wound was 6.5 centimeters above the external auditory meatus and 2 centimeters in front of a line perpendicular to the external auditory meatus: it was 5.5 centimeters behind and 3.5 centimeters above the external angle of the frontal bone. The wound in the scalp was round, but a laceration extended backward about 3 centimeters. The surrounding scalp was not lacerated or contused. Hemorrhage had entirely ceased and had not been profuse. The man's general condition was good. Although he was unconscious, enough reflex remained to cause him to move about when the wound was manipulated. After shaving and carefully cleansing and disinfecting his head he was chloroformed, the external or scalp wound was enlarged and the bone freely exposed. It was found that the depressed fracture of the bone involved an area of a little less than 2 centimeters and that all of this bone was driven down at almost a right angle to the cranium into the cerebrum, so that there was a sharply-defined rim of bone, with some radiating linear fractures, and about 3 centimeters beneath, from the inner table of the cranium, the comminuted fragments lay imbedded in the cerebrum. Outside of this bone the scalp had also been punched out and the fragment was lost. The opening in the bone was enlarged and by careful manipulation the fragments were lifted out of the cerebrum with a pair of narrow forceps. A few spiculae were so small and sharp and deeply imbedded that much care was required to locate and remove them. When the fragments were finally removed free hemorrhage took place from the cerebrum, but was checked by plugging the cavity with iodoformized gauze. Something like 15 cubic centimeters of lacerated cerebral tissue were washed away with a gentle stream of warm sterilized saline solution. The dura was lacerated to shreds and it was quite impossible to close the gap in the membrane. I concluded to pack the whole cavity with iodoformized gauze, and, by careful asepsis, endeavor to obtain healing by granulation. Accordingly, a careful dressing with an outside pressure bandage was applied and the patient put to bed. He stood the operation very well, reacted quickly, and under morphin passed a quiet night. The next day he was quite conscious, answered questions readily and had no paralysis. There had been considerable oozing and the dressings were saturated with blood. I changed the dressing. In spite of the greatest care there was an escape of more cerebral tissue, and as there was

no membrane or scalp to help retain it I saw I should have trouble to prevent the escape of brain tissue whenever I dressed the wound, and every prospect of a final hernia cerebri. I replugged and redressed the wound as before and concluded to wait a day or two. I recollected, in thinking over the matter, that Weir had recently used gold foil to prevent adhesions between the dura and cranium and scalp, and had found it non-irritating, and that rapid and permanent healing occurred in his cases. I had to control the oozing of the cerebral tissue into a cavity and prevent its detachment and escape on account of a complete loss of all its envelopes. I concluded to try a sterilized cup made of heavy gold foil fitted down into the cavity of the cerebrum.

On April 7, two days after the injury, I again had the patient chloroformed, and getting the dimensions of the hole in the cranium I fashioned a cup from the gold foil (which had been sterilized by immersion in a 5 per cent. solution of carbolic acid and then washed off in a warm sterilized saline solution, 0.5 per cent. solution of sodium chlorid) into the shape of a hollow cone, with the base just big enough to fit closely to the inner rim of the inner table of the cranial wound and with a depth of about 2 centimeters. The plugs were removed from the cerebral cavity, with again considerable escape of brain matter, which was washed out by a gentle stream of the warm sterilized saline solution, and the cup immediately introduced, apex downward. I fastened it in place by pressing the foil into the indentations and irregularities of the rim of the inner table and packed loosely into the cup some iodoformized gauze. I incised and loosened the scalp on either side of the wound so that I could slide it over and cover in the opening, sutured it, except a small space in the center through which an end of the bit of iodoformized gauze was allowed to project, and dressed it as before.

On April 14 the wound was redressed, the sutures removed, and also the packing of gauze from the cavity of the gold cup. The wound was perfectly aseptic, the cup firmly fixed and in place, and there was no bulging and absolutely no escape of brain matter. A small bit of gauze was again introduced into the cup to give it solidity, and the dressings were reapplied.

On April 27 the wound was again inspected. There had been no suppuration, and the wound was entirely closed except where the bit of gauze projected from the cup. This was removed and the external wound was allowed to come together. In a few days this was entirely and solidly united. The patient was allowed to be up and about. His faculties were all good, locomotion was good, and in short he showed no indication in any way of having lost any function; nor were there any signs of irritation from the cup. I kept him about two weeks employed most of the time about the wards, doing the work of an orderly, that I might observe him and examine the seat of wound. There was absolutely no indication of any trouble or disturbance. He was discharged quite well May 20. The wound was firmly united and there was no pulsation perceptible through the opening in the cranium.

Case 2. George S., a Hungarian, age 27 years, was brought to the hospital by the ambulance on June 21, 1894. He had been engaged in an altercation with some of his fellow workmen the day before and was struck by a stone thrown by one of them. He was felled to the ground, bled profusely, presumably was unconscious, though this point we could not find out, as we had no interpreter. A local physician was called in who found a comminuted depressed fracture and trephined; possibly he raised some depressed fragments of bone. The scalp wound was sutured and dressed and the patient as soon as practicable sent to the hospital. When admitted the man was not only conscious, but could and did insist upon walking into the receiving room. He was a short, healthy looking fellow. Upon investigation there was found an irregular lacerated wound and a more regular oval wound situated in the right temporo-parietal region. The oval wound was sutured. The sutures were removed and after careful cleansing and disinfection a further exploration showed an extensive comminuted depressed fracture involving the anterior portion of the temporo-parietal region in the right side and the fracture extending downward and forward involving nearly the whole of the temporal fossa. A trephine wound about a centimeter in diameter through the anterior inferior portion of the parietal bone marked the upper limit of the fracture; below, the bone was in a number of irregular fragments and depressed. The patient was chloroformed, the external wound extended down into the temporal region and after careful retraction of soft tissues, during which hemorrhage was rather free, it was found that two large fragments of the temporal bone were depressed and that under the upper edges of these were a number of sharp small fragments which had been driven through the membranes and imbedded in the cerebrum. After raising the temporal

fragments the small fragments were carefully taken out. Considerable hemorrhage followed this and escape of not a little cerebral tissue. It was now seen, after the hemorrhage had been controlled by pressure of iodoformized gauze, that the dura and other membranes had been entirely destroyed at the lower part of the wound near the inferior temporo-parietal junction and that there was a persisting oozing of brain matter. It was quite impossible to bring the dura together throughout the whole area, the fragments of bones were irreparably comminuted and soiled. It was determined, therefore, to supply the place of the dura with gold foil. Accordingly a rectangular piece having been sterilized in carbolic solution (5 per cent.) and washed off in warm sterilized saline solution, the brain matter was washed off with a gentle stream of hot saline solution, together with blood and detritus, and an area of 2 c. by 1 c. which was entirely destitute of any membranous covering was covered in by the gold foil, placed under the border of the surrounding dura, and held down by the pressure of the dura and the large fragments of the bones below. The scalp was immediately sutured, stout catgut drain was introduced at the more depressed part of the wound, and the ordinary iodoformized dressing applied. The wound healed with one change of dressings and the man was discharged quite well and apparently in first rate condition in every respect, July 7, sixteen days after the operation.

Case 3. George E., 20 years of age, Pennsylvanian by birth, was run down by a train of coal cars on the evening of Feb. 19, 1895. He was picked up and brought to the hospital about one hour and a half after the accident. The young man was in a wretchedly low condition when he arrived. He was unconscious, had scarcely any perceptible pulse, extremely pale and relaxed, and covered with dirt, soot and coal dust. Examination showed a complete crush of the left leg up to just below the knee joint, the right foot also comminuted and the tissues involved up to the lower third of the leg. There was also a wound on the left side of the head about 3 centimeters above the supra-orbital ridge, back of the edge of the hair at the forehead, and about 6 centimeters from the middle line; this was a fairly clean cut wound, running in a slightly curved line backward in a general way parallel with the middle line. The left parietal bone was fractured so that the fracture was almost linear. Running backward, it corresponded almost with the area of the external wound. The fracture was about 6 centimeters in length. There was considerable oozing of blood and cerebral tissue. The patient's condition seemed hopeless. The ambulance surgeon had already applied an Esmarch's tourniquet to either limb as near the crushed tissue as possible. The limbs and head were now carefully washed, shaved and disinfected and an aseptic dressing applied. He was hurried to bed and surrounded with hot water bags, and stimulated actively by strychnia and digitalis hypodermatically. He was very restless and required large doses of morphia to quiet him. The next morning (February 20) he was conscious, but dull; his general condition had so far improved that he was etherized and both his lower extremities were amputated. The left one through the condyles of the femur and the right through the lower third of the leg. The depressed parietal bone was also elevated, the cerebral tissue and blood carefully washed away and the scalp sutured. The patient stood these three major operations remarkably well. He began at once to improve, the wounds all did well, the head wound especially. He was very drowsy for several days, but could be aroused and could answer questions. His mental state improved daily and aside from some drowsiness and occasional periods of irritability and restlessness there seemed no cerebral manifestation of evil, until March 3, twelve days after the operation. During the night of March 3 he had a violent convulsion epileptiform in character. The wound of his head was entirely healed at this time and there had been no suppuration. There seemed to be no depression at the seat of fracture and there was no abnormal tenderness. He had no further disturbance until the night of the 7th when he again had a convulsion. On the 8th he had frequent convulsions: toward evening and during the night the convulsive attacks became almost continuous and the patient fell into a very weak comatose condition. Careful observation showed that the convulsion began by turning the face to the right, then twitching of the muscles of the face followed by movements of the right hand and fingers, it then became general. His condition on March 9 was very low, but I determined that there was something remaining at the seat of the fracture which was still an irritant. Under chloroform the scalp was incised along the cicatrix, the flaps turned back and a $1\frac{1}{2}$ centimeter trephine applied at the posterior extremity of the fracture in the parietal bone. After the button was removed by a chisel and a sling steel elevator the

fractured bones (which were seemingly not depressed) were elevated and held up by an assistant. There was pretty free hemorrhage which required hot saline solution and pressure with sterilized gauze to control. The seat of operation was so near the longitudinal sinus I was constantly afraid I should wound it. Luckily this did not happen however. When hemorrhage had been controlled it was seen at once that a detached fragment of the inner table had been driven down into the frontal lobe of the cerebrum and lay imbedded in the softened brain tissue. The dura was entirely destroyed for a space of about 2x3 centimeters, and there was a pretty large escape of brain matter. After all the softened tissue, shreds, etc., had been removed and the offending piece of bone taken out, a pretty large cavity was left in the anterior lobe of the cerebrum near the middle line. Indeed the process of the dura which separates the two hemispheres in the longitudinal fissure was laid bare from its cerebral side on the left. This cavity seemed about 2 c. deep, about 1.5 c. wide and about the same length; The whole of this superficial area could not be covered by the dura. A piece of gold foil cut large enough to come in this space, and prepared as in Case 2, was laid over this cavity and the dura mater sutured and drawn about the foil as much as possible to hold it in place. The large fragment of bone was replaced, but the trephine button was left out, scalp sutured, catgut drain introduced and wound dressed as usual. The patient was pretty low after the operation (the 9th). He had a slight convulsion during the evening. After this there was no further trouble. He had no other convulsion, the wound healed rapidly. There was no paralysis except perhaps a slight facial paralysis which soon disappeared. The mental state was very dull for about a week. He would answer questions intelligently, but slowly and was drowsy. His pupils were dilated more than a week. After this he steadily improved, his usual mental state returned, and he was discharged March 28 quite well.

This case, besides illustrating the usefulness of gold foil, shows to a marked degree the amazing vitality of a human being and the tolerance of multiple synchronous major operations if great care be used to prevent loss of blood.

DISCUSSION.

DR. WM. T. DALBY—The paper of Dr. Estes, read by the Secretary, is an exceedingly interesting one. It opens up a new field in brain surgery, particularly in that character of cases where there is great destruction of bone tissue. Since the author of the paper is not here to defend any points that might be brought out in the discussion, I will say nothing further.

DR. HENRY W. COE—I am sorry the author of the paper is not here because I would like to ask him some questions. The subject is extremely interesting to us. I have seen an operation done for epilepsy in this city (Chicago) in which a plate of platinum was used. The old trephine wound opened up in which there were extensive adhesions, and the cavity was filled with fibrinous material, intimately adherent to the dura. The operator, Dr. Morehead, dissected out the new tissue and put in a piece of platinum. The patient was poor or he might have inserted a piece of gold. The operation was extradural, although he went through the dura mater. I am reminded in this connection that Keen in his work on diseases of the nervous system, which has just been published, refers to the fact, which is contrary to the generally accepted idea, that under present methods the opening of the dura is not a serious undertaking and is not accompanied with very much danger. I telephoned since luncheon to find out how this case was getting along and ran across another in which the operator had used a piece of gutta percha. This operation was also extradural. It was done about twelve days ago. I do not remember the name of the operator. In both of the cases the wounds healed readily and up to date there has been no evidence of the presence of a foreign body. I do not know exactly how thick the piece of platinum was, but it was probably one line in thickness. In the cases which Dr. Estes reports, I understand the gold foil is inside the dura mater, and I for one will watch the history of them with a good deal of interest. In these cases we have a foreign body pressing on the brain, and it will be interesting to know the outcome of them.

DR. H. HATCH—I regret that I was not present to hear the whole of the paper that has been read. Are we to understand that Dr. Estes maintains that by introducing gold foil inside the dura mater it will prevent adhesions and consequently the after effects in the way of epilepsy?

DR. KELLY—I believe that is the idea.

DR. HATCH—A professional friend of mine had a case of epileptic convulsions following an injury upon which he operated. The adhesions in this case were dense and firm. He dissected away the adhesions and proceeded in the manner laid down by Dr. Estes, not applying gold foil. The convulsions did not recur for two or three months, but when they came on again they were as bad as before the operation. It is well to report the unfavorable as well as the favorable cases.

STRUMA GELATINOSA—STRUMA COLLOIDES.

Read before the Chicago Pathological Society, Feb. 10, 1896.

BY M. L. HARRIS, M.D.

PROFESSOR OF SURGERY CHICAGO POLICLINIC.
CHICAGO.

Of the various pathologic changes which may occur in the thyroid gland, that of colloid formation is the most frequent. In order, however, that this colloid formation may receive the title of struma colloides it is not sufficient that a little colloid material be found in the vesicles or follicles throughout the gland as this is often a physiologic condition, especially in later life, but the colloid formation must occur in a circumscribed area or areas, sharply defined from the normal gland tissue and independently of it.

Furthermore, as Wölfler states, there is in these cases an atypical new tissue formation, a budding of the gland tubules, so that what we really have is an adenoma, in the tubules of which the colloid material accumulates, leading to their distension; hence the name applied by Wölfler of adenoma gelatinosum. These new growths may be single or multiple, and when multiple may be scattered throughout a single lobe or both lobes of the gland. The colloid material may liquify, thus forming little cysts, which, owing to pressure atrophy of intervening walls, may coalesce, producing large cysts. As illustrating these different varieties, I will briefly mention the following cases, operated on during the past year:

Case 1. Large single Colloid Adenoma.—E. K., age 21, German; single. Mass size of a goose egg occupying left lobe of thyroid of about one year's standing.

Operation: Enucleation; suture without drainage; primary union; recovery.

Case 2. Multiple Colloid Adenomata of one lobe with cystic degeneration.—Mrs. W., age 44. German, married. Multiple nodules involving right lobe of thyroid, extending from upper part of thyroid cartilage to below the upper end of sternum; of several years' standing; lately increasing in size; considerable dyspnea, voice affected.

Operation: Enucleation of all the tumors, two of which were cysts containing thin, dark, bloody-looking fluid. One of the cysts, size of small hen's egg, extending behind the upper end of sternum, enucleated with some difficulty on account of location. Wound closed without drainage. On second day quite profuse hemorrhage occurred from place where cyst had been enucleated, which was easily controlled by removing a stitch and packing with iodoform gauze. Primary union and recovery without further incident.

Case 3. Large Multiple Colloid Adenomata; both lobes.—Mrs. K., age 44. American; married. Has had large neck for seventeen years. Since last child-birth, three years ago, tumor has grown quite rapidly. Considerable dyspnea, particularly on lying down. Both lobes of thyroid involved.

Operation: Enucleation. Kocher's transverse incision; wound sutured without drainage. Primary union. Recovery.

The tumors removed from Cases 1 and 3, some twenty in number and varying in size from a pea to a goose egg, are presented. That there is an increased growth of gland tissue in these masses is very evident. The new growth starts in the primitive vesicle or follicle of the gland. The connective tissue envelope of the follicle is pushed aside, and being increased in thickness by the irritation produced by the new growth, forms an investing connective tissue layer or capsule to it. It is the presence of this connective tissue capsule that enables one to enucleate these growths from the surrounding gland tissue.

A microscopic examination of sections of these masses shows very beautifully the gland follicles lined with epithelial cells and greatly distended with the colloid material. In the section here presented, which was taken from one of the small and presumably younger growths, are seen toward the periphery, many tubules or follicles which contain as yet no colloid material. The rapid proliferation of the epithelial cells seen in these tubules leading to the formation of double and even multiple layers of cells shows clearly the active part taken by the gland elements in these cases, and substantiates the statement of Wölfler that these growths are all primarily adenomatous, the colloid formation being a secondary degeneration.

Other follicles are seen containing large masses of detached epithelial cells, many of which take the nuclear stain very poorly, while in others the contained mass takes the diffuse eosin stain, in which, however, can be distinguished very faint circular and broken circular outlines of nuclei, showing that here the detached cells have undergone colloid degeneration en masse. In some tubules the amount of colloid material is very small and seems to be produced by the layer of cells lining the follicles, while others are distended enormously and contain in addition to the colloid mass many detached cells about the periphery. The capsule inclosing these masses is not simply the connective tissue septa pushed aside, but there is here also an hyperplasia as the increased number of connective tissue nuclei in the section clearly show.

In the removal of benign growths of this character complete thyroidectomy is no longer permissible, no matter how extensively the gland may be involved. These growths, being encapsulated, can always be enucleated after the method of Socin, except where inflammation or calcareous or other degenerative changes have occurred. The best incision is the transverse cut of Kocher. It affords easy access to the entire gland and furnishes the best scar. This latter point is one of considerable importance and has been particularly studied by Sultzer. He examined the scars in 100 cases following operations by various incisions. Of sixty-two scars following oblique or longitudinal incisions, in only one could the scar be considered faultless; the others either contracted so as to interfere with the freedom or range of motion of the neck or were wide, shining and disfiguring; while of thirty-eight scars following transverse incisions thirty-two answered all the demands of a linear faultless scar. The incision should be free enough to allow easy access to all parts of the gland. The sterno-hyoid, sterno-thyroid and occasionally the omohyoid muscles should be divided and turned aside. In incising the gland tissue down to the capsule of the tumor, proceed where the tissue is thinnest, in other words, at the point where the tumor approaches

nearest the surface, due regard being had for the large thyroid vessels, which are readily recognized breaking up on the surface of the gland. Do not begin the enucleation until certain of being within the right layer of the capsule, as tearing in the gland substance leads to very profuse and troublesome hemorrhage. After the enucleation considerable oozing is frequently encountered, to check which packing with iodoform gauze is commonly employed, the packing being removed on the second day and the wound closed. I have usually been able to dispense with this packing by firmly approximating the walls of the cavity by a few mattress sutures of catgut. The posterior surface of the gland must be avoided in passing these sutures on account of the proximity of the recurrent laryngeal nerve. The mortality of enucleation in these cases is practically nil, being less than 1 per cent.¹ The last point to be considered is the question of recurrence after enucleation. Sultzer was able to follow out sixty-three cases of enucleation. Of these, forty-four remained free of recurrence, while in nineteen, other nodules developed: eight times in the same lobe operated upon and eleven times in the opposite intact lobe.

DISCUSSION.

DR. F. C. SCHAEFER—There came under my care recently a case which might be appropriately reported in this connection. I removed a parenchymatous goitre for exophthalmos four weeks ago from a girl aged 18 years. You will notice that it is similar in appearance, excepting the shape, to the specimens exhibited by Dr. Harris. On looking at it from a distance you might think it was an enlarged kidney. At the time of its removal (four weeks ago) it was six inches long, two and a half inches wide and two inches thick at the central part. At one point above its middle portion it presented a hook-like projection, an "accessory" lobe which extended under the trachea, and as the trachea was already flattened by pressure from the body of the goitre, this accessory portion added materially to the embarrassment of respiration. I succeeded in enucleating one-half of the growth, the remainder had to be excised. The gland is very dense and hard. Microscopically the follicles can be seen packed to distention with epithelial cells, irregular in outline, with an occasional spot of colloid. Undoubtedly the disease began in the follicles and the cells of the parenchyma were stimulated into activity by the cell proliferation in the former. A special point in the case is the exophthalmos. The girl presented all the symptoms of Basedow's disease, excepting the bronzed skin. She had marked tachycardia, pulse rate 145; difficult breathing; husky voice; slight protrusion of the eyeballs; tremors of the muscles of the entire body, more especially of the chest muscles. The patient was excessively nervous, could not sit quietly in a chair, and had extremely restless nights: would toss about in her sleep and was frequently obliged to get up two or three times during the night to breathe. I felt, under the circumstances, that the goitre should be removed. The eyes on ophthalmoscopic examination by Dr. H. M. Starkey and myself showed spots of hemorrhage and anemia in the fundus, also congested veins. Sight very much diminished. R. E. V. 20-200, L. E. V. 10-70. In operating I followed the same incision as Dr. Harris (Kocher's) extending across the neck. On the left side I took out only a small portion of the growth, to avoid the sequela of myxedema. The young lady is improving every day, her respirations are improved, pulse rate 105 and she claims that her sight is already much better. I hope ere long to be able to present the patient.

LEPROSY IN THE ARGENTINE REPUBLIC.

BY ALBERT S. ASHMEAD, M.D.

NEW YORK.

(LEGATION OF THE UNITED STATES,
BUENOS AYRES, Aug. 9, 1895.

A. S. Ashmead, M.D., Dear Sir:—After many days' search and interviews and the incidents therewith connected, I am enabled to send you something in the line which you wish. I inclose copy of two letters from the Director of the Asistencia Publica and Sanitary Administrator of the Government. I also send under another cover copies of works as per memoranda herewith attached. Very truly yours, WILLIAM I. BUCHANAN.

LIST OF INCLOSURES.

1. Two copies of letters from Asistencia Publica.
2. Memorandum: *Lepra Tuberculosa*, tesis para optar al grado de doctor en Medicina, por Gregorio Hunt. Consideraciones sobre un caso de lepra anestésica, tesis para el doctorado, por Jacobo Z. Berra. *Climatologie Médicale de la République Argentine et des principales villes de l'Amérique*.

Letter No. 1, translation:

BUENOS AYRES, July 27, 1895.

To the Minister Plenipotentiary of the United States of America. Mr. Minister:—The Director General of the Public Assistance of Buenos Ayres has the honor of answering the question which Your Excellency has condescended to address to him as to the frequency of leprosy in the Argentine Republic; and gives expression to the information which he has gathered in the pages inclosed. With this object, I greet Your Excellency most respectfully,

I. B. SENORANS.

Letter No. 2, translation:

Notes as to the frequency of leprosy in the Argentine Republic.—The Director of the House of Isolation¹ says in his personal report that the cases of leprosy have been known accidentally in this hospital in the years preceding 1892; it is in this year that figure the first entries with this diagnosis, and statistics show an evident tendency of augmentation in this disease. In 1892 there entered into this establishment five lepers, who remained in attendance until 1893, at which time twelve more lepers were received: the sum total was then seventeen, of whom nine left and eight remained sick. In 1894 fifteen lepers were admitted, which, added to the eight who were under treatment, made twenty-three. Of these twenty-three, six left and two died; so that there remained fifteen, who passed to the year 1895. Now, July, 1895, there are only twelve in attendance. The ordinary form is the tuberculous, however there are some anesthetic cases.

Of the patients attended on, in the hospital of isolation, we have not been able to obtain the nationality: but they are very probably mostly Europeans. Dr. Gache, in his medical climatology, points out to the sanitary authorities the frequency of leprosy in the Argentine Republic, especially in the last year. The Province of Entre-Rios offers an immense number of lepers, and in that region the disease has been observed many years before this. Dr. Moyano, in one year of practice, on 309 patients with skin disease, has met with three lepers, one coming from Brazil, another from the Argentine (Province of Corrientes), and a third, also coming from Argentine, was the son of French people, the father being a leper. This patient comes from Pergamino (Province of Buenos Ayres); his father and four uncles had this same disease developing itself there, but they came healthy from Europe.

Dr. Sommer says that the Province of Corrientes is that which has the largest number of lepers: after it come the Provinces Entre-Rios, Cordoba and Buenos Ayres. In the City of Tucuman, at the time when its population amounted to 30,000, there were seventeen lepers.

In his opinion the tubercular and nervous forms exist in equal proportions. The largest part of the cases presented general symptoms, of which the more constant were cephalalgia and fever; others were characterized mostly by erythematous or pigmented spots, with alterations of sensibility. The same physician believes that leprosy is contagious, and his opinion is based on observation. He thinks that the bombilla (an instrument with which is imbibed an infusion of *yerba mate*) of the *mate*² is the vehicle of contagion.

As to the treatment, the oil of chaulmougra at the dose of 200 drops a day, has been found the best specific.

Dr. Canevaro, a physician of Corrientes, says numerous cases of leprosy come under the observation of the physician, not only among the poor, but also among the rich. He has seen many instances of it in Goya, and other places of that Province. The natives of that region consider contagiousness as principal cause of the disease: this is proved by numerous families in which the disease has broken out. Much influence is also attributed to abuse of alcoholic drinks, and of the meat of "Carpincho," and of pork, of which the poor people consume a great quantity, especially of the first. It is also believed that the atmospheric vicissitudes exercise a great influence upon the development of the disease, especially in the case of people who are compelled by their business to be constantly exposed to the humidity of the soil, and of the atmosphere with insufficient alimentation: for instance, the people who have to travel in the bushes.

Dr. Canton, in the Province of Salta, has found leprosy to exist. The Director General of Public Assistance of Buenos Ayres, intending to prevent the diffusion of leprosy, has advised the respective authorities to adopt means tending to this end.

As a bibliographic remark, I observe here that Dr. Emilio R. Coni, in 1879, published his doctorate thesis on this same disease. Dr. Jacobo Z. Berra, in the same year, and Dr. Gregorio Hunt, in 1886, made their doctorate dissertations on the same theme.

The Minister may give to whosoever wants them the data given above: I add these last two works and the work of Dr. Gache, entitled *Climatologie Médicale*. J. B. SENORANS.

ANESTHETIC LEPROSY.

Considerations on a case of *lepra anesthetica* by Dr. Jacob Z. Berra, Buenos Ayres, 1878.

Manuel Rios, native of Paraguay, is a man of about 46 years of age, a railroad foreman, with a deteriorated constitution, of nervous, lymphatic temperament; good antecedents. Had paralysis of right arm and deviation of the mouth, when about 9 years old; he attributed it to a cold which he caught while perspiring in bed. It disappeared after three months. At 12 or 13 years, he got two buboes, appearing spontaneously. Had never had sexual contact. This terminated after a few days by suppuration. Attack of general articular rheumatism after a few days. At puberty he suffered of a blennorrhagia (non-venereal) after eight days' horseback riding; urinated blood. In 1865 he went as a soldier in Paraguay to Rio Grande, and suffered in the passage through the frontier of Corrientes of a dysentery, which was epidemic in the army. As a prisoner he was sent to Buenos Ayres, where he became a peon on the railway of the east: had perfect health here, until summer of 1870, when he was caught in a great rain while perspiring; he did not change his clothes till night: had chills and fever for five hours. He felt formations after a few days in feet and hands, which lasted a year, more or less: the said extremities remained in such a condition of debility that he could not take with his hands the smallest object: loss of sensibility accompanied it; tears constantly fill his eyes. After months the index finger showed a phlyctena, which burst of itself, letting escape a clear, transparent liquid. An ulcer appeared in its place, of offensive smell; out of this came pus and fragments of bone. Anti-syphilitic treatment tried in the hospital without success. Other fingers became implicated: left hand; then the feet. While these phenomena manifested themselves the sensibility and the motility of the regions affected experienced also profound perturbations, etc.

The differential diagnosis with the mal perforans, does not present great difficulties, if we remember: 1, that the disease occupies principally the level of the points in which the callosities are formed and those which touch the soil: for instances, the big toe, the

¹ Hospital of contagious diseases with 400 beds.

² "Le Mate est l'aliment indispensable à la campagne; il constitue le déjeuner obligatoire du paysan qui ne sort jamais sans l'avoir pris. Dans les villes, il n'est presque plus admis; toutefois dans quelques régions de l'intérieur son usage est tellement exagéré qu'on lui attribue de nombreuses dyspepsies."—*Climatologie Médicale* par le Dr. Samuel Gache.

fifth metatarsian, the inferior face of the calcaneum, and sometimes the dorsal face of the fingers; 2. that it begins by a swelling of the epidermis, which in a short time detaches itself on account of a sero-sanguinolent and purulent secretion falling in an extent of one to two centimeters, when there appears under it a dermis, red and papillous; 3. that the epidermis thickens around the ulcer and forms a very characteristic wheal, which becomes smaller gradually, by the approximation of its borders; 4. that there is not as in lepra formation of phlyctenæ; 5. that it localizes itself in the feet, and shows no tendency to generalization through the other parts of the organism; 6. that sometimes there is anesthesia and when this is the case the anesthesia is limited to the ulcerated point.

Such are the essential characters of a mal perforans; they have nothing in common with anesthetic lepra.

Let us see if we can confuse with any of these three kinds of spontaneous gangrene: 1. that which is caused by an arteritis; 2. that which is the production of an embolism; and 3. the local asphyxia and symmetric gangrene of the extremities.

LEPRA ANESTHETICA. BERRA'S CASE.

In order to exclude the first two it is sufficient to bear in mind, that in our patient there have not existed, and do not exist any alterations of any kind, either in the heart or in the remainder of the circulatory apparatus, which could cause the development of an arteritis, or the formation of embolism, capable of producing the disturbances which are before us. Besides, the slow march and the long duration in our case exclude affections of this kind.

As to the third kind, we know that the local asphyxia which precedes the symmetrical gangrene of the extremities, shows a course and development entirely different.

According to Raynaud, who has given the best description of it, this affection is a variety of dry gangrene, which is distinguished by two notable characters: 1. the absence of any anatomic alteration appreciable of the vascular system, and 2. invariable symmetry of its manifestations.

The local asphyxia begins almost always by a finger, forming an affection rather common, known by the name of *dead finger*. The skin assumes a tint of

faded white, sometimes yellowish; it looks exsanguinous, and the sensibility seems to be exhausted. This state is of short duration; after a few minutes, sometimes of an hour or two, the parts return to their normal state, the reaction being in certain cases accompanied with a rather sharp pain. When this state instead of being limited to one or two fingers, extends itself to a whole section of a member, an enfeeblement of the arterial circulation is observed. In cases a little grave, the skin takes a bluish-white hue, violaceous, slatey; venous livid stains appear in distinct places; the cutaneous sensibility is abolished; sometimes the patients complain of a very sharp pain; presently the reaction is produced, the stains lose their livid color, the skin, little by little, resumes its normal coloration, and everything is again in order.

In cases where the accidents of gangrene are to be manifested things come to pass in the following manner: Sometimes the extremities become pallid and exsanguinous, or they take a lilac color; the patients complain of formication and itching; later on, the skin and the nails assume a violaceous color, and those parts are icy cold. Sometimes the skin is violet from the beginning, the patient feels itching; he thinks he has chilblains, but this itching is presently replaced by a pain, which sometimes is very acute. Quickly, livid stains show themselves along the fingers and ascend sometimes to a great height in the corresponding member, the dark tint increases, and the fingers become completely black and anesthetic; small phlyctenæ appear at the extremity of the last phalanx; they burst and leave the dermis uncovered. These small ulcerations persist for some days; in other cases the phlyctenæ is dried subsequently, but the gangrene does not extend itself; the wound, on the contrary, cicatrices leaving a small conical tubercle, more or less salient. The same series of phenomena presents itself, in the same finger or in the next fingers. When this process has taken place frequently, in the same finger, the latter is remarkable by the tapering form of its extremity by the hardness of its tissue, and by its faded appearance. In some individuals, the finger takes from the beginning, that parchment-like form; the skin is lion-like yellow, and after sometime pelli- cles thick and very hard, detach themselves by tatters.

In other cases the gangrene presents from the beginning all its intensity: the nail is completely black, the little phalanx takes a hue more or less dark, there is a real mortification; but the alteration is not deep. After a few days, a work of elimination begins and very soon scales of one or two millimeters in thickness detach themselves, leaving uncovered the papillæ on which fleshy buttons develop themselves; the cicatrization comes soon. Very frequently this mortification shows itself in a parallel direction in the corresponding fingers; sometimes it has been observed in the four members, and hence the name of symmetrical gangrene, which Mr. Raynaud has given to it. It happens not rarely, that these stains present themselves symmetrically in the heels of the two extremities. In some individuals these different states may manifest themselves at the same time. This mortification is sometimes observed in the nose, and the pavilion of the ear.

Beside the symptoms which are revealed by this description of the disease there are differential characters as follows:

1, the invasion of anesthetic lepra is slow and increases gradually, while that of the symmetrical

gangrene of the extremities in its chronic form, is very brusque as a rule, and reaches very rapidly a certain intensity. 2, the prognosis of leprosy is always grave; that of symmetrical gangrene is, as a rule, benign. 3, anesthetic leprosy is fatal, gangrene of the extremities never causes death by itself.

There exists an affection known in Guinea by the name of Yaws, which produces deep alterations in the skin, and in the subcutaneous cellular tissue: in order to distinguish it better from anesthetic leprosy, we shall describe it in a few words.

It attacks specially the badly fed negroes, and it is eminently contagious. It begins by white stains, looking like the pricks of fleas, or like small papule, which occupy especially the forehead. After a few days they convert themselves into broad pustules covered with irregular crusts, and of little adherence, beneath which are found ulcers, of a deep red in well constituted subjects, and are white and depressed in feeble and sickly people. As a rule there are various successive eruptions, and there is also, as in the pian of America a pustule larger and more elevated. The duration of the disease is six to ten months; the fungosities finally are quite depressed and leave only slight cicatrices. This disease was considered by many authors as a peculiar form of syphilis, which was to be combatted by sudorifics and mercury. To-day we know that it is a cutaneous affection in which the last remedy is harmful.

In order to differentiate it from pachyderma or elephantiasis of the Arabs, we have only to remember the gross and formless aspect which this disease gives to all the parts it affects: that it is produced by repeated inflammation of the skin, and by frequent and constant obstruction of the veins, and lymphatic vessels which distribute themselves through the same, occasioning sometimes an enormous increase of volume of the dermic conjunctive tissue, of the subcutaneous and intermuscular tissue, and also of the periosteum; that it keeps as its preferred seat the leg, which acquires a volume double or treble of the normal; it presents itself with less frequency in the superior members, the scrotum, the penis, and labia majora. We must finally bear in mind, that in this disease, there is no anesthesia.

TUBERCULAR LEPROSY.

Dr. Gregory Hunt (*Lepra tuberculosa*. Tesis para optar al grado de Doctor en Medicina, por Gregorio Hunt, ex-practicante interno del Hospital Nacional de Clinicas, Miembro del Circulo Médico Argentino y de su Comision Directiva, Buenos Aires, 1886) says:

Genesis and Etiology.—For some, exclusive use of fish and especially of salt or rotten fish is bad; for others, the meat of pork daily eaten, either salted or not, is in the same conditions.

We shall try to prove that an exclusive diet can not be a sufficient cause to produce leprosy in the places where it is endemic.

Leloir has observed that the fishermen of Norway, who live almost exclusively on fish, which is moreover often a state of putrefaction, suffer nothing but chronic gastritis. What would be sufficient to prove, that this deplorable diet is not the cause, says the same author, is that the fishermen and peasants of the southern and north sides of that land, although their diet is as bad as that of the west coast, are yet not attacked like the others.

What has mostly called the attention is the water which they drink, and the manner of preserving it.

That water is not drinkable, and is kept in small wells, in the middle of immundities and mires of salt water which are found by the sides of the houses in which these people live. Is not that perhaps the origin of this disease?

As to the pork, there is nothing that justifies in saying that it is the only cause of this affection: for although in certain localities where the latter is endemic, we see some of the inhabitants eat much of it, there are other places where it is not eaten at all, where nevertheless the disease exists. We see finally that the inhabitants of the Riviera (Italy) where it is also endemic, people live on vegetables, fruits, potatoes, etc. So that certain alimentations condemned by some physicians as being the cause of the development of leprosy, do not exist there.

Neither can insufficient alimentation be its cause. The Siberian peasants, the inhabitants of Terra del Fuego, the poor families of the great centers of population like Paris, London, even Buenos Ayres in which there are so many wretches, whose nutrition is not sufficient, are, in spite of that, rarely affected.

On the contrary there are persons well fed, and whose life is hygienic enough, who become the victims of this disease. These are a minority, indubitably, but let us not forget that there are more poor people than rich. On the other hand, the former are more exposed to disease than the latter.

Organisms debilitated either by bad diet, alcoholism, excesses, etc., are more exposed to sufferings, than strong ones; these repel very often the morbid germ, because they are not in a condition of morbid opportunity. Thus it becomes clear that all things being equal, the same organism resists, for instance, in one case the action of the cold while the same organism changing somewhat in power of resistance in consequence of bad alimentation, drinking, etc., when it is again exposed to this action, is affected, for instance, with pneumonia.

After all these considerations which we have enumerated in a summary manner, we can not accept the distinct causes which we have named, as being the exclusive producers of leprosy, although they may work, as predisposing agents, preparing the soil. . .

He believes in inherited predisposition, but that the disease itself is not inherited. . . . The physicians of Rio Janeiro believe that this cause (heredity) is indubitably in the disease of which we speak but that only it skips generations as is observed with tuberculosis. It is an open question whether many of the cases which are supposed to be hereditary are not cases of contagion from father to son. An author who has observed the life of the lepers of Norway, and their manners, says that the way of living of the people and of many families, explains to us how, even in the absence of any heredity, a disease very little contagious, can develop and extend itself. The peasants of Norway are very dirty according to Leloir; most of them never took a bath. They wash sometimes (once a week) their face and their hands, the feet once a year, but the rest of the body remains untouched by water, from their birth to their deathbed.

Their clothes, which they never take off, even when they go to bed, are generally of wool. They are never washed, the filth is allowed to accumulate and these same clothes, when they are not rotten, are transmitted from generation to generation (Leloir). Now is it

not possible that these immundities carry the contagion to the healthy subjects? We believe that this may be one of the means of propagation of leprosy in Norway, and that many cases which are considered as hereditary result from contagion. . . . As to contagion, he says: No, it is not possible that in face of the great feats of modern pathology, contagion can be denied and isolation declined! . . .

Parasitic Origin of Leprosy.—To sum up, we believe that the experiments which have been practiced up to this time, both in man as well as in some animals, are not sufficient to declare that this disease is inoculable.

Diagnosis.—The diagnosis of tubercular leprosy is very difficult when the disease is in the period of invasion, and this difficulty decreases only when there appears the eruption of maculae and especially tubercles. The latter are characteristic, and he who has once examined a leper can never mix up this disease with any other disease. We have seen that the symptoms which are observed in the period of invasion are like those presented by other infectious diseases. At this period the diagnosis is very difficult, and we can only have presumptions more or less founded, when we find together many of the symptoms characteristic of the disease, and hereditary antecedents, which show that lepers have existed in the family, and the patients coming from an infected land. Only in that manner we can think of a diagnosis; but we can not affirm yet in an absolute fashion that we have before us a case of leprosy.

In the period of eruption of maculae we meet also with some difficulties in making the diagnosis. The most experienced physicians have made blunders; but if we make a long study of the history and symptoms which present themselves, we can succeed in establishing the diagnosis.

One of the affections with which confusion would be most easy, is roseola syphilitica; but the maculae of leprosy have their seats of predilection, and are also larger, since they can reach the dimensions of the palm of the hand, and be accompanied by phenomena of anesthesia and dysesthesia; and, finally, it will be distinguished by the antecedents and the specific treatment of syphilis. There may be found some difficulties in some other affections of the skin, like the dry eczema, erythema, and papulous marginate purpura. The spots of the disease of which we occupy ourselves do not present desquamation, and if they exist they are very rare; the same thing does not happen with most of the morbid conditions of the skin. Anesthesia or dysesthesia, alteration of the sebaceous glands, and the falling of the eyebrows, the beard, as well as the antecedents of the patient, and the situation of the maculae will serve as a basis to establish our diagnosis. The pigmented maculae, which are almost always accompanied by dysesthetic phenomena at their level, and if their center becomes achromatous, by an absolute anesthesia, can not be confounded with certain normal pigmentations of the skin, and much less with vitiligo.

Morphea and scleroderma in patches are differentiated from leprosy, according to Leloir, by the absence of anesthesia or only a very small diminution of sensibility, and by the violaceous little ring which surrounds the patch of the morphea, flat and wide.

The leprous pemphigo is distinguished without much difficulty, if we take into account the antecedents of the patient, the number of bullae (they are

rare in leprosy), the cicatrices "nacaradas," the anesthesia at this level, the concomitant nervous phenomena, hyperesthesia and anesthesia of the extremities. Such are the skin diseases which having some points of resemblance with leprosy, might induce us into errors of diagnosis. . . .

Prognosis.—Leloir refers to two cases of cure observed by Dr. Kaurin.

We see, therefore, that if in the annals of science there are found cases of cure those cases are very rare. The rule of the termination of leprosy is death, cure is the exception. In presence of all the antecedents, we do not hesitate to say that the prognosis of this disease is very grave. . . .

Treatment.—Hygienic treatment has given the best results. Transplantation (removal to another country) is recommended. Temperate climates are preferable, also altitudes; nutritious diet, not too seasoned. Exclusive diet is generally harmful; it ought to be animal and vegetable. Milk, meat, fresh and well cooked vegetables, boiled eggs, etc., is the best alimentation for lepers; pork, salads, crustaceans, alcoholics, tea and coffee are to be prohibited; cleanliness.

Isolation of the lepers is a means sufficiently efficacious to prevent the propagation of the disease, and statistics prove the fact. . . .

The natives of America did not know any such disease; it is a pathologic inheritance bequeathed to us by Europe. Among the natives of the New World, who have not as yet mixed with civilized races, there is no leprosy.

Dr. Hunt, in referring to the alleged cure by Unna, of a case of leprosy, says that Dr. Unna's conclusion is unscientific, since he ought to have taken into account all the considerations "which we have mentioned," in order not to expose himself unpreparedly to criticism.

He says that in the first period of the disease it happens readily that it offers improvements which look like cure and which may endure for years without there being any cure. He refuses to accept Dr. Unna's statement that leprosy is curable.

CASE OF RUPTURED TUBAL PREGNANCY, WITH REMARKS.

BY J. WESLEY BOVEE, M.D.

WASHINGTON, D. C.

The history of this case is as follows: Cora M., colored, 22 years of age, was admitted to my service in Columbia Hospital for Women, March 2, 1896. She was married and had one child three years ago after a normal labor. Her menstrual flow began at the age of fifteen, generally lasted three days, was regular, profuse and on the first day was usually very painful. It appeared Dec. 12, 1895 and lasted five days. Up to this time she enjoyed good health. Vague pelvic pains and indigestion ensued and continued to the time of her first severe attack. This occurred Jan. 20, 1896, when the pelvic pain became intense and she passed from the vagina a large blood clot. She had missed a menstrual period and thought this was an abortion. From this she soon recovered and was out of bed in two days. The pain and flow continued, however, and February 17 she applied for relief at the outdoor service of Columbia Hospital. There an examination was made and a fluctuating mass was found behind the uterus. She was advised to enter the hospital at once but returned home and

resumed her household duties. On February 27, she was attacked with sudden, severe pain in the lower part of the abdomen, followed by frequent attacks of syncope. She remained in bed, attended by Dr. C. Marshall until her coming to the hospital March 2. The flow has continued since the abortion. The bowels have not moved since February 28, and she complains of severe pains through the abdomen. She was very feeble; unable to walk, the extremities were cold and she seemed nearly exsanguinated. There was slight edema of the legs and the abdomen was distended by fluid and gas. The mucous membranes of the lips, tongue, conjunctivæ, and vagina were very pale. No glandular enlargements were noted. The urine had a specific gravity of 1.024 and contained albumin and pus; the pulse was very feeble and the temperature subnormal.

A diagnosis of probable ruptured tubal pregnancy was made. When the abdomen was opened March 5, 1896, we were not at all surprised by the pouring out of a large quantity of black, semi-solid blood as soon as the peritoneum was incised. By passing my fingers downward, the top of the slightly enlarged uterus was felt and recognized and the right appendage, other than a few adhesions of the ovary, was found to be normal and not removed. The ovary contained a corpus luteum. The left Fallopian tube was much lengthened and in its first two or three inches was apparently normal. It, however, continued around backward, much as does the round ligament in front, and ended in a sac attached to the rectum, the uterus being free from the sac. This sac had ruptured and, lying partly in and partly out of it, were the fetal membranes, the fetus and a large mass of blood clots. The ovary of this side was apparently normal and contained no corpus luteum. The fetus was of about six weeks gestation. The appendage was removed and the abdomen flushed with hot water, large clots being washed out of it, even from behind the liver and near the spleen. No drainage was used and the wound was closed with kangaroo tendon, buried both subperitoneally and subcutaneously; 1500 c.c. of normal salt solution was thrown under the skin and she made a complete recovery.

Tubal pregnancy has been found to be far more common than was formerly supposed. Rupture has occurred before the attention of the physician is called to it nearly always. That it has become more common is, no doubt, due to the more frequent resort to abdominal section as a means for dealing with the various pelvis troubles and that the condition is seldom found before rupture, is due to the fact that it usually gives very little annoyance previous to that accident. Many times operations for other conditions are planned and when the seat of disease is reached, a ruptured tubal pregnancy is found. Wide and prolonged discussion of the advisability of operating on ruptured tubal pregnancy, after the danger from hemorrhage has passed, has led to the almost universal opinion that it should not be treated on the expectant plan, but that nothing short of surgical interference will entirely remove all danger. It has been seen that dangers nearly as great to the woman as the loss of blood may ensue, and that surgery is necessary to restore these unfortunate women to health. Infection of the blood clots, or of the sac, with the possibility of septic peritonitis, sometimes fatal, is by no means an infrequent feature in those cases that were considered very mild, *i. e.*, those in

which the blood loss has been slight, especially when it was inside the broad ligament and consequently limited in amount. If not peritonitis, then septicemia tries to do the injury to life and health. Cases have been frequently reported in which temporizing operations were done for the removal of pus when death was not far away and the lives of the patients saved, and this in the very mild cases even, perhaps, undiagnosed. The very bad cases either die promptly or are operated on as a *dernier ressort*. The milder cases, therefore, are comparatively safe ones for operation and should not be allowed to proceed into the dangerous channel above mentioned. They, as well as the severe ones, should be, as a rule, operated as promptly as the existing conditions will permit, though often the operation may be postponed a few days to the advantage of the patient. It should be thorough, if possibly admitted by the condition of the patient, during the operation. If we find she does not stand the anesthetic well, or that the organs most easily affected by ether or chloroform are at all pathological, or that shock seems at all marked, the operation should be as rapid as possible and confined as much as possible to the removal of the ruptured tube, blood clots, membranes, etc., and a rapid closure of the abdominal wound, with or without drainage. If time and conditions permit, the abdominal and pelvic cavities should be thoroughly irrigated and all clots washed out. When the irrigating fluid returns clear it is quite certain the peritoneal cavity is well rid of them. If the case be a recent one and the hemorrhage considerable, it may be wise to pour into the abdomen a few liters of normal salt solution, just before the closure of the peritoneum is finished. The absorptive system will take up as much of it as is necessary to restore the usual blood pressure of the individual and the surplus, if any, will be carried off as waste. The same solution by hypodermoclysis is extremely beneficial in these cases, it being a fairly rapid way of putting it into the circulation and not being liable to over-distend the circulatory system as sometimes does occur as a result of infusion directly into the veins.

On March 23, 1895, I operated for ruptured tubal pregnancy in which septic infection was already present as a result of an attempted criminal abortion by means of the insertion of a catheter into the uterus and retaining it there a very long time, the patient taking quite a long railroad journey in the interim. This case was published in *The American Journal of Obstetrics*, N. Y., 1895, xxxii, No. 3, 387. The following September 27, I did another operation for ruptured tubal pregnancy at seven weeks. The case was reported in *The Virginia Medical Monthly*, Richmond, 1895, xxii, 957. In those two cases, as well as in this one, the injured tube was the left one, which tends to confirm the statement of Lawson Tait, "That the left tube is nearly always the one pregnant in tubal pregnancy." In one of these two cases the corpus luteum was found in the ovary on the side opposite to the pregnancy, as was the condition in the case here reported. The relations of the appendages in this case are not devoid of interest. The right ovary was down in Douglas' pouch and firmly adhered there. The pregnant tube was also fastened down in close proximity to it. Whether the ovule was expelled by the ovary into the peritoneal cavity and accidentally found its way into the Fallopian tube, or whether the tube embraced the ovary of the opposite side can not be stated; nor can we be confident that the

pregnant tube was pervious at the time of the impregnation. It is just possible the spermatozoa passed through the right tube into the peritoneal cavity, then into the outer end of the left one and there impregnated. This, however, seems too far-fetched to receive much earnest consideration.

I have reported this case to show how frequently cases are found in which tubal pregnancy has ruptured a few days or even weeks before and in which the danger from hemorrhage has been practically passed, but in which repeated losses ensue and in which other dangers confront the patient and stand ready to prevent a recovery, and to also show the advisability of attempting to relieve this class of cases by operation or, very often, to save their lives. I believe I have done about seventy-five abdominal sections during the time in which these three cases of ruptured tubal pregnancy have occurred. At that rate it would seem that 4 per cent. of abdominal sections are for this grave condition. This statement, I am inclined to think, will be borne out by the experience of men who have had a much greater amount of this kind of work than I have had.

1404 H Street.

TYPHOID FEVER.

BY F. M. GREENE, M.D.

LEXINGTON, KY.

Until recently typhoid fever has been regarded as a self-limiting disease, always ending in lysis and occupying a period of three or four weeks' duration. It is observed of varying degrees of intensity, from a mild attack, in which there may be only slight elevation of temperature, and the patient does not take to his bed, to the severest type, in which from the beginning there is great prostration, and the patient rapidly succumbs to the intensity of the poison.

Complications and sequelæ are to be dreaded alike in the mild and severe forms, and not infrequently in the midst of a mild attack, or after convalescence has apparently been established, we may have ulcerations of the ileum, resulting in grave hemorrhages, or perforation of intestine, with peritonitis and speedy death.

Under the old régime, there were observed four distinct periods to the disease, and a schematic representation of each was characteristic and typical. During the first there was a gradual increase of pyrexia with evening exacerbations reaching sometimes 105 to 106 degrees. The second period was one of continued fever, with only slight remissions. In the third the disease was remittent, with exacerbations less and remissions greater. The fourth was one of intermittence and there was a gradual return to normal temperature. In fevers of inflammatory type the pyrexia is never continuous for any great length of time, since in all are observed more or less remissions during twenty-four hours.

It is usually during the second period that grave complications begin to appear. The patient becomes apathetic and drowsy, takes less interest in his surroundings, with muscular movements feeble and uncertain. Wandering in mind, he appears confused and forgets to withdraw his tongue when asked to protrude it. Already red at tip and edges, the latter now becomes dry, cracked and fissured, sordes upon teeth, gums and lips, with altered blood issuing from the nostrils. Subsultus tendinum, picking at imaginary objects, and with hallucinations, he attempts to leave his bed, or wildly asks to be taken home.

These symptoms now deepen into coma; the urine and feces are passed involuntarily. During this period or later we have the serious complications mentioned above and resulting from ulcerations of the ileum.

If the patient survive, he now enters upon a slow and tedious convalescence, which may be extended indefinitely. The brain or nervous system may suffer permanent injury, or the patient fall a prey to septicæmia, pyæmia or tuberculosis. We have drawn the above picture in order to contrast the disease as treated formerly with that under the modern disinfectant and antiseptic treatment. The pathology of typhoid fever has long been known; its etiology has only been recently established.

The typhoid bacillus enters the system through food or water, and finds its habitat primarily in the glands of the ileum. In his pathologic anatomy and pathogenesis Ziegler says: "The marked changes in typhoid fever appear chiefly in the lower part of the ileum, and upper part of the colon. They are seldom met with much higher or much lower in the intestine." The old and stereotyped idea that typhoid fever will run a prescribed course, uninfluenced by remedies, still prevails to a great extent in the profession, and an expectant plan of treatment is usually adopted. Brandt, of Stettin, a few years ago, introduced the hydriatic or bath system of treatment in typhoid fever, and with a reduction of mortality heretofore unknown in the history of the disease. This in a great measure superseded the use of all other antipyretics.

The application of cold water by effusion or submersion is followed by reduction of temperature and amelioration of symptoms generally. The tongue becomes moist, delirium disappears and the patient is disposed to take nourishment. The bath plan furnished the safest and most effective antipyretic known at the time of its adoption. Serious complications and sequelæ, however, followed even this treatment, and it does not in all cases prevent hemorrhage or perforation. The *modus operandi* of the Brandt treatment has not been fully explained, but experiments have shown that it is an effective means of promoting leucocytosis or increase of the white corpuscles.

Mestchnikoff's theory of phagocytosis explains the manner in which a cure is effected by the natural powers of the system. The leucocytes show a positive attractive force (chemiotaxis) toward the proteids constituting the body of the vegetable parasites known as bacilli, and on coming in contact with, digest, destroy or remove them from the system. Applying this theory to the disease under discussion, the conflict is between the leucocytes and typhoid bacilli which, having first entered the glands of the ileum, multiply rapidly and enormously in the warm blood plasma. The leucocytes are doubtless overcome and poisoned *en masse* by the overwhelming numbers of bacilli; a toxin results, which proves rapidly destructive of the tissues and blood itself. The eminent author on fevers, Graves, desired to be inscribed upon his tomb the motto, "*I feed fevers*," but did not know that in doing so, he was only reinforcing battalions of leucocytes engaged in deadly conflict with pathogenic germs.

If our knowledge of its etiology be correct as that of its pathology, it follows that there must be two principal indications in its treatment, first to destroy the germs at their point of entrance (*locus læsionis*), and secondly, to counteract the toxin resulting from

their presence in the blood. Several years ago Dr. John Eliot Woodbridge claimed that he had succeeded in aborting the disease by the use of certain remedies in its earlier stages. In a paper read before the AMERICAN MEDICAL ASSOCIATION in San Francisco, and again at its meeting in Baltimore recently, he fully explained the treatment, claiming that it was abortive and rapidly curative. In the discussions which followed the reading of papers upon the treatment of "Typhoid Fever in Children," much time was consumed in discussing the Brandt method, which was highly extolled, and only slight allusions were made to the Woodbridge method, and in terms not altogether complimentary. Having treated a number of cases of the disease during the past summer and autumn, and succeeded in aborting it, we have no hesitancy in adding our testimony to its superiority over all other methods.

Under the antiseptic and disinfectant method we have really but two periods to this formidable disease—first, a period of rapid reduction of temperature, and secondly, the period of convalescence. By destroying the germs early in the attack, and before the development of toxins, we at once abruptly interrupt its course and prevent complications so frequent when the disease has existed for any great length of time. Tympanites, when present, disappears, dry tongue and delirium are prevented, diarrhea ceases, pyrexia ceases by the tenth or twelfth day, and the patient at once enters upon a favorable convalescence. With mind clear and muscular strength preserved, he is enabled to leave his bed by the end of the second week, and solid food may be allowed him much earlier than under the old régime, because there are no ulcerations of the ileum to contraindicate its use.

We believe that these results are brought about by both intravascular and intestinal disinfection. It has long been known by physicians that intestinal disinfection is an important indication in the disease, and the difficulty heretofore has been to find a remedy or remedies to accomplish this, and at the same time prove harmless to the system.

Of the combination of remedies recommended in the Woodbridge treatment, it may be difficult to determine the precise rôle played by each. Purgatives were thought to be contraindicated in the disease formerly and in the new treatment they are indicated. Both the podophyllum and calomel fulfill important indications, the latter as a disinfectant and purgative, and the former aids in clearing out the alimentary canal, especially the colon, which is now regarded as the sewer of the system.

Bintz claims, that in its passage through the alimentary canal, the protochlorid of mercury is changed into the bichlorid, and the latter is now regarded as one of the most efficient disinfectants and germicides known to the profession. It is now believed that most, if not all, intestinal affections are caused by specific germs, and we may thus understand how calomel gained such reputation in their treatment. From simple catarrh to the more grave affections of cholera and dysentery, it is regarded as superior perhaps to all other remedies.

The danger from hypercatharsis is not regarded, since the diarrhea will cease and the system immediately rally after destruction of the germs. We believe the carbonate of guaiacol to be the active agent in the destruction of the typhoid bacillus both in the intestinal canal and in the blood and tissues of the body.

It belongs to the phenol group and is the active principle of creosote. Chemically pure, guaiacol is of offensive odor and burning taste, and an irritant. It is insoluble in the stomach. Combined with carbonic acid, it is innocuous and non-irritant, and it has been found to allay irritability of the stomach and prevent abnormal fermentation. Von Heyden found that after leaving the stomach, it was decomposed into carbonic acid and pure guaiacol in the intestines, and it is here that it exerts its proper medicinal effects.

We have observed under its use that the characteristic typhoid stools become more consistent and lose their offensive odor. The odor of creosote is detected now in both the urine and feces. The menthol, thymol and eucalyptol act as intravascular disinfectants, doubtless, as their odor is detected in the perspiration. Large draughts of sterilized cool water promote both diaphoresis and diuresis, by which poisons are eliminated from the blood. It is proper to speak of cases in which these remedies are sometimes not well tolerated, when given in their regular routine. An irritable stomach will sometimes reject formulas 1 and 2.

By the use of sinapisms, and the substitution of guaiacol carbonate, alone, in 5 to 10 grain doses every three to four hours, for from twenty-four to thirty-six hours, we have been enabled to control the irritability and return to the above formulas. Ptyalism will sometimes supervene upon the use of the mercury and we will be obliged to withdraw it. The guaiacol is now to be given, and the simpler aperients, as Hunyadi water as recommended by the author. We may not be able to abort the disease as early with these complications, but its course is still very much shortened and sequelæ prevented. It is superior to the Brandt treatment, because the latter will not abort the disease or prevent serious complications.

responding Member Société D'Electro-thérapie, France; Mem-
ber Electrical Association of New York; Member American
Medical Association; Member of the French Laryn-
gological Society, Paris, France.

NEW YORK.

This preliminary paper which I have the honor to present to you, gives mine and other experimental work with the kinetograph, kinetoscope and phonograph. Here, I wish to show the practicability of rapid photography by means of the kinetograph and the rapid reproduction of these photographs after their preparation herein described for the kinetoscope, by this means giving life to each and every possible mo-

tion. This mechanical aid gives us the power to photograph and reproduce every possible physiologic phase capable of visible movements, and in certain pathologic conditions showing their special visible symptoms. Not only can the utility of this instrument be applied in our science, but also to all others. It is my hope in submitting this communication to your critical judgment that what follows herein will give a satisfactory proof of the possibilities for further development and use in this field of study; also that it prove as useful to others, as it has done in these researches made up to this date.

1. GENERAL REVIEW OF FIFTY YEARS OF PHOTOGRAPHY.

Taking a survey backward of fifty years of photography and contrast this with the possibilities of to-day, when in the darkest of the dark caves or cellars, or on the blackest of nights, the tyro photographer, armed with his little camera, and pistol loaded with magnesium cartridge, can obtain a picture full of vigor and marvelous in detail. This chasm has been bridged over in the fifty years since Daguerre gave before the French Academy of Sciences the secret of his wonderful process. The journey down the photographic history of those fifty years is full of wonderful struggles of mind over matter, strange hopes awakened, magical discoveries set aside, fascinating theories exploded, practical inventions pushing to the front, large areas covered, and more and more individuals of both sexes benefited by this discovery of the progressive scene painter, until to-day hundreds of thousands contribute to our knowledge and happiness in the practice of photography whilst gaining their daily bread.

The story of Daguerre's struggles and victory may well be told at this time, after a lapse of little over fifty years since his grand discovery. It was on the 19th of August 1839, that Arago, the noted French astronomer, before crowded halls and courts, gave the practical details of the process for fixing upon a prepared plate the images of the camera-obscura, and France, by giving an annual stipend to Daguerre and his associate, M. Isidore Niepce, provided that all their compatriots should be free to practice the new art. Arago's speech is even now most entertaining reading and should be familiar to all votaries of the art of photography, but we must content ourselves with little more than a review of some of the points which may indicate the appreciation in which the discovery was held at the time, and the prophetic insight that saw how full of value to science as well as art this great invention would prove to be. M. Arago dealt with the scientific problems of optics and chemistry involved in the search, showing the length of time after the knowledge that nitrate of silver blackened in the light before any successful experiments were made to fix the images of the camera by its use. He paid a tribute to the memory of M. Joseph Nicéphore Niepce, describing the process by which, after three days exposure, he had succeeded in forming an image which could be retained on the plate. Such a process could of course only serve for copying engravings or drawings, and was impracticable for landscape, architecture or portraiture.

By an accident a meeting was brought about between Daguerre and Niepce, and a partnership formed, which ended only with the death of Niepce in 1833, after which time his son Isidore continued the researches. Here it may be well to say, though it is not

a part of M. Arago's speech, that Daguerre's processes proved to be so much more rapid and perfect than those Niepce was using that in the latter part of 1837 an agreement was signed between the two partners permitting the name Daguerre to be associated with the discovery, and it was many years before the small "d" headed the word daguerreotype.

Up to the time of Arago's explanation public curiosity had for a year or more been awakened by accounts of the wonderful pictures, and some of the pictures have been shown. Baron von Humboldt, Biot, Arago and other savants were mentioned as having been made familiar with the work, and offering their testimony to the value they placed upon the discovery. One story was afloat that the Emperor of Russia stood ready to give Daguerre 500,000 francs for the secret, and English papers of the day expressed themselves as surprised that so magnificent a reward should have been declined. The sum finally paid was 10,000 francs annually to both of the inventors—6,000 to Daguerre and 4,000 to Niepce, Daguerre receiving the larger sum as he also divulged his secret for making his very popular dioramas. It would be proper here to describe this process of Daguerre but other and more pressing matter crowds upon us. It is now practically obsolete, and though very beautiful, more delicate even than any processes by which it has been set aside, it still has shortcomings which soon condemned it. Other methods of picture-making admitting a practically endless multiplication, became in time more popular and have held their own to the present time. The daguerreotype was a positive process; that of Mr. Fox Talbot, of England, to which late improvements can be traced, was a negative process. In 1839 before Daguerre's methods were explained, we find Mr. Talbot writing to the French Academy claiming priority of invention, which certainly, in the light of what we know of Niepce's success, could not be awarded him. Mr. Talbot's process differed so entirely both in means and result from the daguerreotype that it was useless to compare the results, so greatly superior was that of the Frenchman to the Englishman's. The one employed highly polished silver-covered plates of copper; the other, sensitized paper with a grain which deprived the resulting print of much delicacy. Daguerre did not with his invention succeed in portraiture, and the honor of first making a likeness has been always awarded to our own Dr. J. W. Draper.

Without the camera it would have been impossible at picture making. That invention we owe to the brilliant experimentalists John Baptiste and John Vincent Porta, those two twin spirits, the Castor and Pollux of the natural philosophy of the 16th century, and whose scenical museum delighted and awed, by its optical illusions and treasures of curiosities and its natural magic, all learned natives and foreigners. It is a long jump from the so-called beginning of the art of drawing by the tracing of the pretty girl's shadow on the white wall to the chemie discoveries which made it possible to fix permanently that shadow.

Miniature painting, which was a popular mode of portraiture when photography was first discovered, was little by little driven from the field by its less expensive and generally more faithful rival. It is true the daguerreotype was a costly process at first, and efforts were constantly being made to cheapen it. It held its sway until 1851, but soon after that time was set aside by the albumin and the collodion process,

this latter soon having the field all to itself. We can not permit ourselves to enter into the respective merits of processes, yet there are four great divisions, or perhaps we may say three great divisions and one small one, which it is well to bear in mind in reviewing the last fifty years. These would be the daguerreotype from 1839 to 1851; the albumin process on glass plates made practically in 1849, but soon, in 1851, set aside by the collodion process, and fourth, the great popularizer of photography, the gelatin bromid dry plate in 1871.

Previously to all this history of fifty years review there is to be found the published record of a discovery by Fabricius in 1536 when seeking the elixir which was to restore youth. He threw some sea salt into nitrate of silver, and noted that the chlorid of silver precipitated, though of a white color, became black as ink by exposure to sunlight. But this knowledge does not seem to have been utilized until Scheele in 1777 rediscovered the fact, and a few years afterward Professor Charles, the inventor of the hydrogen gas balloon, spread the chlorid of silver on paper, and placing the head of one of his pupils in a beam of sunlight, saw that the shaded portion remained clear, while the rest of the paper rapidly darkened. Still there was no chemic substance known that would retain the image, so, unless the sheet were put away in a dark place, the whole of it would soon blacken. It might be looked at from time to time in a subdued light or by artificial, or the silhouette thus formed could immediately be cut out and the perfect profile thus saved. The long sought compound by hyposulphite of soda, was invented in 1799, but it was not until twenty years later that Herschel found its power of dissolving haloid salt of silver. Three other chemicals, chlorin, iodine and bromine, were discovered respectively in 1774, 1811 and 1826, so that we find the materials ready only a little while before the final discovery of their marvelous powers. One of the first of illustrated works in which photography was employed was Mr. Fox Talbot's "The Pencil of Nature," though in 1840, among holiday books advertised as suitable for presents is one in beautiful binding, "Excursions Daguerriennes." Only a few years past over from that period and a need for orthochromatic photography was felt, especially in the use of medicine, etc., and researches were made to that end which have now born fruit, though the new plates are still far from perfect. All through those years we note the patient search for the power not only to translate the image into black and white, but to retain the gradation of color so beautifully pictured on the ground glass in the camera.

A binocular camera was invented by Sir David Brewster for taking pictures for use in Professor Wheatstone's new stereoscope. Lenses of similar power were placed side by side, distanced by the average measurement between the eyes. This was in 1849. We must remember that up to that year paper and the silvered metal were the grounds sensitized for use in the camera. Then came the use of albumin spread upon glass so that it would hold the material used to sensitize the paper in the calotype process. This avoided the grain of the paper and gave a more perfect picture.

In the United States it was estimated that there were ten thousand daguerreotypists by 1850, and some five thousand workmen who were engaged in the manufacture and sale of plates, cases, chemicals and apparatus, or in other ways receiving their support from

indirect connection with the art. But the story is too long to tell how and when photo-lithography, photographing on blocks of wood for engravers, and the various uses to which photography is now put, were first employed. Little by little it has traveled the world over, educating and delighting everywhere. When we try to note the spread of this art, we are astonished at the uses to which it is now put. How active the human brain is still in invention the thick octavo volume published each year by the Patent Office containing only patents bearing upon photography, improvements in cameras, shutters, tripods, etc., testifies. Many hundreds of books have been written upon the history of photography and its practice in every direction. Last year's Annual gives the titles of forty-four added to the list. There are over sixty periodicals, appearing in different countries, some weekly, others monthly, a few semi-monthly. Of societies the list gives in America 54, and in foreign countries 107. Even in Japan there is a periodical devoted entirely to photographic matters, called *Sashin Shimpa*. It is a monthly and sells for 15 sen, or about 12 cents.

The facility with which the prepared plates can be manipulated, the ease with which hundreds of the new celluloid films can be carried about, the quality they possess of retaining their sensitiveness for months, the fact that exposures may be made in Central Africa or in the neighborhood of the north pole, and the image not developed until the traveler returns to his comfortable laboratory at home, are all magical advances in the fifty years since Daguerre told his secret. What the next half-century will do with the subtle powers of the sensitive plate remains to be seen. To artists familiar with the study of color any hope that the gradations of hues shall be retained by a negative image and communicated to a positive print seems absurd. Constant progress is being made toward the bettering of the interpretation of color values. The mysteries of chemistry are being tested; chlorophyll, eosin, erythrosin and other new compounds are being employed. Bright, thoughtful, intelligent men are reaching into the unknown world of light and chemistry, experimenting and recording with scientific accuracy the story of their researches. The difficulty consists in obtaining gradations of black and white corresponding to the luminosity of the colors of nature. In copying paintings this is especially desirable, and already a great advance has been made. Even the amateur finds in the market prepared plates with which he can produce results in which equivalent gradations of tones stand for the various tints of color. These plates are called orthochromatic (right color). Experiments in this direction will continue until the full beauty of the image of the camera will be kept in so far that our reds will no longer be coal-black, our blues not faded or white, and our bright yellows dull and gloomy. Experiment in photographing an orange by the ordinary and by the orthochromatic plate will show the advantage of using the latter.

Bearing upon this point comes the latest news, that the modern theory of color sensation due to the excitement of the three sets of nerve fibrils is put to service by Mr. F. E. Ives. He, the account says, "produces simultaneously three negatives from three differently prepared plates by light passed through three screens of various colors, his object being to produce negatives each representing the intensity with

which light affects one of the set of nerve fibrils in the eye. Lantern pictures are made from these negatives, and projected on a screen by a triple lantern. One picture passed through a red that affects only the fibrils excited by red, one through a similar green, and one through a suitable violet, the result being a representation of the landscape or object photographed in its true colors." Mr. Ives has published a book dealing with this subject, which he calls "A New Principle in Helichromy."

Against the clumsy apparatus of the first daguerreotypists we can set an array of cameras of most perfect mechanical construction, each fitted with some special contrivance endearing it to its inventor, and possibly to others. We find the colossal structures in use in certain galleries, and the popular so-called "detectives," the inconspicuous vest camera, or still smaller ingeniously contrived boxes for photographic purposes. To the advance in the construction of lenses, and to improvements in the shapes and principles of cameras, is due, as well to improved chemic processes, the quality of late photographic work. It is interesting to learn why the lenses in existence at the time of the invention of the daguerreotype could not do the work they were called upon to perform. The lenses constructed for use in the telescope and microscope embraced too small a field, including only at most a few degrees, while that for the camera frequently now embraces ninety degrees when employed for landscape work. The portrait lens needed a much smaller field, twenty or thirty degrees being enough, but required to be so large as to let plenty of light through it, and thus reduce the time of sitting. Many were the defects in the early time due to badly constructed lenses. The fifty years have brought improvements of inestimable advantage, and the variety and quality of the lenses now in the market show the progress of the optician's art.

One of the latest improvements, for which the tourist must be very grateful, is the use which has been made of celluloid, on which, instead of glass is spread the sensitive film. One firm called these plates "ivory films." Where once the traveler burdened himself with boxes of heavy glass, he may carry to-day twelve dozen "films" for each box of one dozen glass plates. Stripping films or gelatin and the sensitive emulsion on rolls of paper are admirable for the traveler. It is needless to dwell on the value photography has in corroborating the statement of the tourist who returns from a strange and little-known country. M. Le Plongeon told me of the incredulity with which his friends regarded the drawings which he brought back from his first visit to Central America. Any artist of an inventive turn could have made such pencilings. Not so with the photographs taken during his second visit. The statements of the camera were accepted, their authenticity undoubted. However untrained in drawing, the author may now gather material for illustrating his writings as he journeys up and down the land, for from the lightning express even he may make his "snap shot," feeling quite certain he has a valuable record, which the trained artist can "work up" for him.

The uses to which photography is being put this year can hardly be told. Its value in illustration is well known to all. Here it has helped to popularize artistic work, and cheapen the cost of its production to a surprising extent. Now but a few hours need pass before the thought of the artist is made the

joy of the reader, drawing, photographic copy, relief plate, and printing following one another with nineteenth century speed. From the coarse outline of the newspaper "cut" to the wonderful reproduction of paintings by the photogravure process we mount on stepping stones of victorious achievements in photography, made to serve with reliable accuracy the common and the elevated, the political cartoon and the *édition de luxe*. The reproductions in color of the works of aquarellists are imitatively deceptive, and their educational influence of incalculable value.

We must not pass over the scientific value of Mr. Maybridge's publications on the action of man and the lower animals, or "The Horse in Motion." Upon these records, however absurd and laughable some may be, we must base our knowledge, intelligently using it for artistic purposes. It is well known that the camera can tell us what it sees when the plate is exposed but one two-thousandth part of a second, whilst the human eye can open and shut in about the one-tenth part of a second. We can not, then, say that photography is true for us when it pictures the rapidly revolving wheel as if it were motionless. If an artist paints the spokes, the wheel does not appear to go round; if he paints the blurred effect of the whirling wheel, we accept it as a representation of speed. There are photographic and optical as there are microscopic and optical truths. We do not paint a drop of blood as it looks through the microscope, but as it appears to our eyes. From the unquestioned statement of fact as concerning the action of animals we must train our eyes to see better the combination of position of body and action of limbs, and determine how far old methods are good, though false, and how far the new scientific truths must force us to change the ordinarily accepted and conventionalized forms.

The uses to which science has put photography are very numerous, from records of the infinitely little to the infinitely great: from microscopy, which deals with the invisible, to the vastness of astronomic wonders. The latest contributions to our knowledge of the sun, moon and stars, made by photographs taken by the aid of the powerful telescope at the Lick Observatory, strongly contrast with the researches into the invisible world of nature revealed through the microscope. Dr. Draper made the first daguerreotype of the moon in 1840; Foucault, of Paris, first succeeded in making a picture of the sun in 1845; and it was 1850 before Professor Bond, of Harvard College, made the first daguerreotype of a star. In 1851 Dr. Busch, of Königsberg, photographed a solar eclipse. Two scientists, Professor Schuster and Mr. Lockyer, in 1862 obtained a photograph of the spectrum of the eclipsed sun. In 1881 Dr. Henry Draper had successfully photographed a nebula, and later the spectrum of a star. Even the aurora borealis has been photographed in 1889.

In connection with the study of spectrum analysis, photography has played a most important part, for it has recorded lines not visible to the naked eye—lines revealed only by the photograph in that part of the spectrum in the violet and lavender regions, and even beyond, where all is dark to us. In the study of stars by this procedure we learn how some are like our sun, others glowing masses of matter just beginning to burn, and still others nearly burnt out, like Arcturus and Aldebaran. We marvel, when we think how feeble seems the light of the stars, to learn that only as much

light as can come through a slit one three-hundred and fiftieth of an inch is permitted to affect the sensitive plate. Again, the movements of the earth would in the two hours required to form an image soon carry the light off the plate were there not ingenious mechanical apparatus by which the image is always kept at the same place on the plate. And now photography is not only used for mapping out the known heavens, but the camera reveals to us the presence of stars which the human eye has not seen. For many years Miss Maria Mitchell and her assistants have photographed the ever-changing sun spots. Astronomers from all over the world have met in Paris and arranged a plan for using photography to obtain a picture of the entire heavens. Cameras will be set up in numbers of observatories in many countries, and many negatives made of the entire contents of the universe. It is proposed to catalogue two millions of the brightest stars and note their position with great precision, as until such maps exist many other astronomic problems can not be solved. We know, for instance, that our sun with its planetary system is voyaging through space. These charts will help determine the route and circumstances of the journey.

Dr. Galton's composite photography has been too well described to claim more than a word in recognition of an attempt to put photography to a scientific use. In this country Professor Stoddard, of Smith College, has made many interesting studies and published several articles upon the subject, and Dr. Noyes, in two pictures of the insane, gives composite types showing expressions that perpetuate themselves in individuals during mental disease.

Photography enables publishers to duplicate in little valuable works and store away small negatives of large folios or manuscripts during the process of publication. Trade uses photography to picture its new furniture, gas fixtures, china, etc., reproducing thus objects too bulky for the "drummer" to carry about with him. Instead of the slow process of copying by hand the geometric designs furnished by the kaleidoscope, numberless changes can be readily photographed in a short time, and furnish suggestive material from which to work. The wall-paper manufacturer uses photography to reduce or enlarge patterns; the delicate figures on watch faces can now be made by its use. These watch dials have been painted by hand at a cost of a dollar each. Now, it is said, a photographic process has been purchased by a watch company by which these dials can be made at the slight expense of ten cents each, electric light serving as well as daylight for their manufacture. Even the quality of steel has been tested by photographic examination. The microscope shows steel to be composed of an agglomeration of crystals, by the difference in which its quality may be determined. The piece of steel to be examined at a certain foundry was heated until it was white, when it was photographed, and the resulting negative examined by the microscope. Those little toy pictures in watch charms have to be made by the aid of the microscope; it is said that only one man in New York can do such work. Even fraud can be proved by the use of the camera. A Berlin merchant was detected in crooked ways, and illegitimate after-entries of a number of his accounts were shown by photography. Blue inks appear much lighter than brown. A chemic test destroys the original, but the faithful plate leaves it intact whilst telling the story of the fraud.

In war photography has been used since the English made pictures in the Crimea. Balloon photography has become quite an art. Balloons are said to be perfectly safe from rifle or artillery fire if 700 yards above the ground. Electricity is made to play its part in exposing the plate in the camera attached to the balloon. During the Franco-Prussian war and the siege of Paris small photographic copies of valuable documents and daily papers were made and rolled into quills, which were fastened to carrier pigeons, and thus taken to their destination without the lines. The Eiffel Tower in Paris has been offered Professor Marey to enable him to make studies in photography of birds in flight, and very instructive results are anticipated. Many will remember the picture of the experiment at Willett's Point when the donkey's head was blown off by the use of dynamite, but the picture was taken before the body fell.

The late Mr. Baden Pritchard, whose work in the Woolwich laboratory made him famous, conceived the very valuable as well as feasible idea of reducing the map of a country on little gelatin films so small that fifty or more could easily lie in the top of a field case. They could readily be employed and clearly read by the aid of a magnifier. To render them very serviceable they were tanned so as to be waterproof. In the English army a photographic wagon is used which is fitted up with two cameras and several lenses, so as to make plates of different sizes or for varied purposes. One of the outfits is so contrived as to be readily packed on a mule. Bromid paper and material for making platinotypes are also carried. Both in our army and navy photographic outfits are furnished and some of our officers have become very expert. Photography may be applied to surveying, as Lieutenant Reed, of the United States Army, has described. It may also serve for studies in meteorology. Photographing rifle bullets and cannon-balls in motion has become an everyday matter, but a novel experiment is said to have been made not long since in Berlin by Professor Treason, who arranged within a cannon-ball a sort of camera which recorded the character of its flight. A tiny pin-hole admitted light, and a sensitive plate within the ball recorded the twists and turns of the projectile in its passage through the air. The gun was fired point-blank at the sun, which sent a beam upon the plate, recording itself as a point, but as the ball swerved more away from the sun a spiral line was formed and marked upon the plate.

In Germany there are many photographic schools, and in one establishment in the midst of very beautiful scenery in the Bavarian Alps more than one hundred pupils have been educated. Last year there was a summer school of photography at Chautauqua and lectures are given each winter at Columbia College. The result of such systematic study ought eventually to advance the art, though at present the students deal principally with practical and scientific problems. At the Cooper Institute and Young Women's Christian Association, in New York, students are trained to skilfully retouch negatives, and thus photography helps a large class in obtaining a livelihood.

There is a side of the practice of photography which humanitarians will welcome. It has been suggested that the camera be used as a substitute for the gun, and pictures rather than corpses be bagged. In all seriousness the suggestion is well worthy of consideration, for the health-giving tramp and the difficulty of the sport are equal in both cases. There

would be a test of the veracity of the sportsman that would doubtless advance the morals of the hunting fraternity. To the fisherman the camera might be valuable to chronicle the marvelous size or number of the day's catch, even if it could not quite take the place of Ik Walton's favorite sport. The naturalist might gain much information of the habits of wild birds and game from the sportsman's album at the end of a season.

There is one service to which photography has been profitably applied which demands consideration, and as it is practiced most effectively in France, it may be well to make a few notes of the photographic establishment at the Prefecture of Police in Paris. Here there is a system of picturing criminals which in connection with another system of measurement, makes it easily possible to identify them. Head, ear, index finger, waist, foot, and the height of the whole figure, as well as the breadth of the extended arms are carefully measured and recorded, as are also any distinctive birth marks, moles, scars, etc. Then the prisoner is taken to well-lighted galleries in the upper story of the building, where pictures of the face in front view and profile, of half and full figure, are made. Since the late improvements in rapid plates it is possible to obtain these pictures even when the subject is refractory. By the use of artificial light 20,000 pictures the size of postage stamps can be made in a single night, and sent broadcast over the country to the police force. There are said to be over 100,000 photographs of different criminals, 40,000 of this number being of women and children. These pictures are now, by the assistance of the classified measurements, so arranged that it is an affair of but little time to determine whether the new comer has ever been in the clutches of the law or not; and if he has, to fix upon him his past crimes and punishments. Modern police the world over have found photography of great assistance, but the systematic care shown by the French might profitably be employed everywhere. The law recognizes the authoritative testimony of photography and often employs it. Photography for the purpose of identification is not necessarily confined to the criminal class. It was employed in 1876 on the season tickets of exhibitors at the Centennial Exhibition at Philadelphia. Another way in which it is serviceable is in reproducing in small size, so that they can be mailed unmounted, the newly finished oil paintings of artists, who may thus reach patrons and show the subject of the new work. Art dealers in America are constantly receiving such photographic notes from European correspondents, and familiar with the general character of workmanship, they can readily determine whether they wish to order or not. Sometimes notes of color accompany the photograph.

Artificial light in the practice of photography has long been found serviceable. The burning of magnesium wire and the electric light furnished sufficient illumination under full control. Within the past two years various compounds have been put upon the market which have popularized the taking of pictures by night, either using fulminating compositions or employing the alcohol lamp and the dry powdered magnesium.

Early in the history of photography its service to architecture was discovered. To-day it brings to every student authentic records of the past, the story of every age, from the lintel architecture of far-away Egypt to the primitive log hut of the Western settler.

In the quiet of one's study one may consult details of Moorish intricacy of design, the stately temples of Greece, or the strange gargoyles of a Gothic cathedral. Reproductive processes have cheapened the cost without lessening the value of these pictures, so that the student may store away treasures in their portfolios. Even in more practical ways the blue print is made to duplicate the design of the architect, and enable him by a little outlay of time and money to give his patrons a copy of his own elaborate work. So, too, may the architect keep informed of the progress of buildings being constructed in distant places away from his office, from plans he has made. Careful photographs taken frequently will show every stage of the work, and avoid many journeys which would otherwise be necessary. By this means our government is able to control from the central office the payments for work done in foreign lands. Engineers also employ photography for a similar purpose.

Philip Gilbert Hamerton may be quoted as an appreciator of photography when he writes in one of his thoughtful essays on landscape: "Instantaneous photography is not so valuable for stormy seas in sunshine as in dull weather, because it confounds foam and glitter, but the fidelity with which it renders minor waves is quite beyond all human rivalry. The excellent photographs of yachts in motion which are now so common, contain endless and most authentic information about all kinds of minor waves and ripples. A collection of them is even better than nature itself, so far as form only is concerned, for no memory can retain the natural form with any approach to photographic accuracy. Painters make constant use of these invaluable memoranda, and by their help, and the education they give to the eye in preparing it to see nature itself, a greatly increased veracity in the drawing of water has penetrated even our current newspaper illustrations."

One can not close even so incomplete a review as this of the first half-century of photography without a reference to the position it holds with regard to art. Though it would require a long essay to deal with the subject as it merits treatment, it is important to make certain confessions of blighted hopes, and at the same time to look with tempered enthusiasm into the future. As an aid to science, as a recorder, as a duplicator, photography has helped advance civilization. Of itself it has failed to occupy the place it may yet hold as a means for expressing original thought of a fine order. With its recognized qualities and in the hands of a thoroughly trained worker perfectly familiar with the laws of chemistry and optics, and with artistic feeling and training, it may be placed on a plane where its beauties will force from all acknowledgment that it has powers which rank it as one of the finest of the graphic arts.

II.—THE EXPERIMENTAL RESEARCHES ON RAPID PHOTOGRAPHY BY MEANS OF THE KINETOGRAPH AND KINETOSCOPE, ETC.

To our Edison, in the year 1887, the notion presented itself that it was possible to devise an instrument which should do for the eye what the inimitable phonograph does for the ear, and that by a combination of the two, all motion and sound could be recorded and reproduced simultaneously. This idea, the germ of which came from the little toy called the zoetrope, and the former combined work of Maybridge, Marie and others has now been accomplished, so that

every change of facial expression and any other visible movement can be recorded and reproduced life size. The kinetoscope and kinetograph of to-day's construction is only a small model illustrating the future possibilities and its present stage of progress. With each succeeding month new changes are brought into view. It can already be forecasted from what has been done, that in a very short time these works of Edison, Dickson, Maybridge, Marie and others who will enter in this field of investigation will be crowned with successes heretofore unknown. These already explored fields bring us to recognize the known and future contingencies of being able to reproduce the many thousands of varieties of motions and expressions known to us in medicine, either as physiologic or as symptomologic in a variety of diseases. Its usefulness does not stop here by any means. The arts in all their branches claim its services also.

The synchronous attachment of rapid photography with the phonograph was one of the early thoughts of this inventor, in order to record and give back impressions to the eye as well as to the ear. The comprehensive term for this invention is the kinetophonograph. The dual talking machine is the phono-kinetograph and the reproducing-machine the phono-kinetoscope, in contra-distinction to the kinetograph and the kinetoscope, which relate respectively to the taking and reproducing of movable but soundless objects. The initial experiments took the form of microscopic pin-point photographs, placed on a cylindrical shell corresponding in size to the ordinary phonograph cylinder. These two cylinders were then placed side by side on a shaft, and the sound record was taken as near as possible synchronously with the photographic image impressed on the sensitive surface of the shell. The photographic portion of the undertaking was seriously hampered by the defects of the materials at hand, which, however excellent in themselves, offered no substance sufficiently sensitive. How to secure clear-cut outlines, or indeed any outlines at all, together with phenomenal speed, was the problem before him which puzzled. The Daguerre, albumin and kindred processes met the first requirements, but failed when subjected to the test of speed. These methods were therefore regretfully abandoned, a certain precipitate of knowledge being retained, and a bold leap was made to the Maddox gelatin bromid of silver emulsion, with which the cylinders were coated. This process gave rise to a new and serious difficulty. The bromid of silver haloids, held in suspension with the emulsion, showed themselves in an exaggerated coarseness when it became a question of enlarging the pin-point photographs to the dignity of one-eighth of an inch, projecting them upon a screen, or viewing them through a binocular microscope. Each accession of size augmented the difficulty, and it was resolved to abandon that line of experiment and to revolutionize the whole nature of the proceedings by discarding these small photographs, and substituting a series of very much larger impressions affixed to the outer edge of a swiftly rotating wheel, or disk, and supplied with a number of pins, so arranged as to project under the center of each picture. On the rear of the disk, upon a stand, was placed a Geissler tube, connected with an induction coil, the primary wire of which, operated by the pins, produced a rupture of the primary current, which in its turn, through the medium of the secondary cur-

rent, lighted up the Geissler tube at the precise moment when a picture crossed its range of view. This electric discharge was performed in such an inappreciable fraction of time, the succession of pictures was so rapid, and the whole mechanism so nearly perfect, that the goal of the inventor seemed almost reached.

(To be continued.)

MEDICAL PRACTICE ACTS.

PRACTICE OF MEDICINE IN RHODE ISLAND.

A law was passed in Rhode Island in 1895 making it the duty of each town and city clerk to keep a "Medical Register," one full page thereof to be set apart for the registration of each physician in his town or city. When any physician shall die or remove from the city or town, the clerk is to make a note of same at the bottom of the page. On the first day of January in each year he is to transmit to the State board of health a duly certified list of the registered physicians. His fee for registration is fifty cents. Following this, it is made unlawful for any person to practice medicine or surgery in any of its branches, within the limits of the State, who has not exhibited and registered in the city or town clerk's office of the city or town in which he or she resides, his or her authority for so practicing medicine, as prescribed, together with his or her age, address, place of birth and the school or system of medicine to which he or she proposes to belong; and the person so registering shall subscribe and verify by oath, before such clerk, an affidavit containing such facts, which if willfully false, shall subject the affiant to conviction and punishment for perjury. Authority to practice medicine under this law shall be a certificate from the State board of health. The board is, upon application, to issue a certificate to any reputable physician practicing or who desires to begin the practice of medicine or surgery in the State, who possesses any of the following qualifications: 1. A diploma from a reputable and legally chartered medical college, endorsed as such by the State board of health; 2. Satisfactory evidence from the person claiming the same that such person was reputably and honorably engaged in the practice of medicine or surgery in the State prior to January 1, 1892. Any person not qualified as so provided, before practicing shall present himself before the State board of health and submit himself to such examination as the board may require. The board shall examine any person presenting himself and if the examination is satisfactory shall issue its certificate. Fee for examination is \$10. Applicants may present their credentials by mail or by proxy. Not more than \$2 shall be charged for any certificate. Nothing in this law shall be so construed as to authorize any itinerant doctor to register or to practice medicine in any part of the State. The board may also refuse to issue its certificate to any individual guilty of grossly unprofessional conduct of a character likely to deceive or defraud the public, and it may after due notice and hearing revoke certificates for like cause, appeal in such cases being given to the supreme court. Nothing in this law shall be so construed as to discriminate against any particular school or system of medicine, or to prohibit women from practicing midwifery, or to prohibit gratuitous services in case of emergency; nor shall it apply to commissioned

surgeons of the United States army, navy or marine hospital service, or to legally qualified physicians of another State, called to see a particular case, but who do not open an office or appoint any place in the State where they may meet patients or receive calls. Any person living in the State, or any person coming into the State who shall practice or attempt to practice medicine or surgery in any of its branches, or who shall perform or attempt to perform any surgical operation for or upon any person within the limits of the State for reward or compensation, in violation of this law, shall, upon conviction thereof, be fined \$50 and upon each and every subsequent conviction shall be fined \$100 and imprisoned thirty days, or either or both; and in no case, where any provision of this law has been violated, shall the person violating it be entitled to receive compensation for services rendered. To open an office for such purpose, or to announce to the public in any other way a readiness to practice medicine or surgery in the State, shall be to engage in the practice of medicine within the meaning of this law.

DENTAL LAW OF NEVADA.

An act to insure the better education of practitioners of dental surgery, and to regulate the practice of dentistry in the State of Nevada, was passed in 1895. It creates a board of examiners, to consist of five practicing dentists, to be appointed by the governor from a list of candidates furnished by the Nevada State Dental Society. Regular term of office is four years. After making special provision for persons already engaged in the practice of dentistry in the State, it is enacted that any and all persons who shall so desire may appear before said board, at any of its regular meetings, and be examined with reference to their knowledge and skill in dental surgery, and if the examination of any such person or persons shall prove satisfactory to said board, it shall issue to them a certificate to that effect. The board shall also indorse as satisfactory, diplomas from any reputable dental college, when satisfied of the character of such institution, upon the holder of such diploma furnishing evidence satisfactory to the board of his or her right to the same. All certificates issued by the board shall be signed by its officers, and such certificates shall be prima facie evidence of the right of the holder to practice dentistry in the State of Nevada. The fee for examination is \$10. Any person who shall violate any of the provisions of this act shall, upon conviction, be fined not less than \$50, nor more than \$200, or be confined six months in the county jail. All fines or penalties recovered accrue to the common school fund of the county. Any person who shall knowingly and falsely claim or pretend to have or hold a certificate of license, diploma or degree, granted by any society, or who shall falsely, and with intent to deceive the public, claim or pretend to be a graduate from any incorporated dental college, not being such graduate, shall also be liable to the above penalty. Any person receiving a certificate of qualification from the board must have it registered with the county clerk of any county or counties in which he may desire to engage in the practice of dentistry. Failure, neglect or refusal to have a certificate so registered, for period of six months, works a forfeiture of the certificate, and no certificate, when once forfeited, shall be restored, except upon the payment to the board of examiners of \$25 as a penalty.

MAINE MEDICAL ACT.

A law was passed in Maine in 1895 to regulate the practice of medicine and surgery within that State. It provides that the governor, with the advice and consent of the council, shall appoint six persons, residents of the State, who shall be graduates of a legally chartered medical college or university having the power to confer degrees in medicine, and who shall have been actively employed in the practice of their profession for a period of five years, who shall constitute a board of registration of medicine. Six years is the full term of office. Regular meetings are to be held in March, July and November of each year. On and after January 1, 1896, the board shall examine all applicants for registration as licensed physicians or surgeons. Each applicant must give satisfactory proof of being twenty-one years of age and of having good moral character, and possessing a reasonable amount of average knowledge in the branches of science he desires to practice in. Examinations shall be, in whole or in part, in writing and shall be of an elementary and practical character. They shall embrace the general subjects of anatomy, physiology, pathology, materia medica, therapeutics, surgery, the principles and practice of medicine, obstetrics, or such branches applicant to possess. On and after the above date, thereof as the board may deem necessary for the it shall be illegal for any person not duly registered by this board to practice medicine or surgery, or any branch thereof for gain or hire within the state. Whoever not being registered as required shall so practice or shall advertise or hold himself out to the public as a physician or surgeon in the state, who appends to his name the letters "M.D.," or who uses the title of a doctor or physician meaning thereby a doctor of medicine, shall be punished by a fine of not less than \$100 nor more than \$500 for each offense, or by imprisonment in jail for three months or both. This act shall not apply to the commissioned officers of the United States army, navy or marine hospital service, or to a physician or surgeon who is called from another State to treat a particular case and who does not otherwise practice in Maine, nor to prohibit gratuitous service or the rendering of assistance in emergency cases, nor to medical students who prescribe or operate under the direction of some registered physician or physicians, nor to midwives who lay no claim to the title of physician or doctor. Neither shall this act apply to persons practicing hypnotism, magnetic healing, mind cure, massage, Christian science, or any other method of healing if no poisonous or dangerous drugs are employed nor surgical operations performed; provided, such persons do not violate any of the provisions of this act in relation to the use of "M.D.," or the title of doctor or physician. The board after a conviction before a proper court, for crime in the course of professional business, and after hearing, may by unanimous vote, revoke any certificate issued by them and cancel the registration of the person to whom it was issued. It has also power to suspend or revoke any certificate by unanimous vote, in any case where same certificate has been wrongfully obtained or any fraud connected with the registration. It shall be the duty of the board, its members or agents to investigate all complaints regarding non-compliance with or violation of the provisions of this act and to bring all such cases to the notice of the proper prosecuting officers.

TO REPORT BIRTHS IN RHODE ISLAND.

A law passed in Rhode Island in 1895 requiring physicians and midwives, on or before the fifth day of each month, to report to the clerk of each city or town a correct list of all children born therein during the month next preceding, at whose birth they were present, stating the date and place of each birth, the name of the child (if it has any), the sex and color of the child, the name, place of birth and residence of the parents, and the occupation of the father. A fee of twenty-five cents for each birth so reported is to be paid by the city or town in which the report is made.

PRACTICE OF MEDICINE IN DELAWARE.

Realizing that "the safety of the public may be endangered by incompetent physicians and surgeons, and due regard for public health and the preservation of human life demands that none but competent and properly qualified physicians and surgeons shall be allowed to practice their profession," a new law was passed in Delaware in 1895, regulating the practice of medicine and surgery in that State. It provides that there shall be established a Medical Council of Delaware, consisting of the Chief Justice of the State and of the Presidents of the two State Boards of Medical Examiners provided for in the act. This council shall issue certificates for license to practice medicine and surgery to such applicants as have presented such diplomas and successfully passed such examinations as are required. The two boards of medical examiners are to be separate, one representing "The President and Fellows of the Medical Society of Delaware," and the other "The Homeopathic Medical Society of Delaware State and Peninsula." Each board shall consist of five members, whose regular term of office is two years, their appointment to be made by the governor from the members of said societies. Each board, not less than one week prior to each examination, shall submit to the Medical Council questions for thorough examinations in anatomy, physiology, hygiene, chemistry, surgery, obstetrics, diagnosis, therapeutics, practice of medicine and materia medica. The Medical Council shall select the questions for such examinations from the lists of questions submitted by the Board of Medical Examiners of the candidate's election; and should there be candidates for examination of any other school than the two designated in this act, they shall be examined by the council and some reputable practitioner in the State of such school, by the council to be selected, upon questions to be selected from standard text books on the above subjects as taught by the school selected by the candidate. The examinations are to be conducted in writing. They may be conducted by a committee duly authorized by said boards. The applicant must pay a fee of \$10 and furnish satisfactory proof that he is more than 21 years of age, is of good moral character, has obtained a competent common school education and has received a diploma conferring the degree of medicine from some legally incorporated medical college. Applicants who have received their degree after the passage of this act must have pursued the study of medicine for at least four years, including three regular courses of lectures in different years, in some legally incorporated medical college or colleges prior to the granting of said diploma. Such proof, if required, shall be made upon affidavit. The clerk of the peace of any of the counties of the State shall issue a license signed by the governor and coun-

tersigned by the secretary of State and sealed with the seal of his office, certifying that such person is authorized to practice medicine and surgery in the State, conformable to the laws thereof, to any person who shall present to him a certificate of the Medical Council. It was also provided that such a license should be issued to any person who had been qualified in one of the counties of the State prior to the passage of this act. Moreover, its provisions are not to apply to physicians who are practitioners of any other State coming into Delaware in consultation with any lawful practitioner of medicine and surgery in the latter State. Nor does the act in any way apply to dentists or dental surgery. And nothing in it is in any way to interfere with the operation of Chapter 117, Volume 13, Laws of Delaware, relating to revenue—otherwise all prior laws on this subject are repealed.

SOCIETY PROCEEDINGS.

Chicago Pathological Society.

Regular Meeting, Feb. 10, 1895.

The President, DR. WELLER VAN HOOK in the Chair.

DR. M. L. HARRIS read a paper on Colloid Goitre, and exhibited specimens of same. (See p. 663.)

DR. D. N. EISENDRATH read an abstract of a paper entitled
SPONTANEOUS DISLOCATIONS OF THE HIP-JOINT OCCURRING
IN THE COURSE OF ACUTE INFECTIOUS DISEASES.

Traumatic dislocations of the hip are of such relative frequency that they interest the surgeon but little more than dislocations of the other joints. Not so with spontaneous luxation of the hip. But few cases of this kind have been reported. They were first observed, in 1853, by Lorinser, who reported a dislocation of the hip occurring spontaneously during typhoid fever. Roser, in 1857, called attention to the fact that this condition was known to Hippocrates, who ascribed it to hydrops of the joint. Numerous post-mortems made during the present century confirmed this theory. Parise attempted to reproduce it by injecting fluid into the joint, and found that the head moved away from the acetabulum. The capsule in order to stretch was obliged to assume a spherical shape, pulling the head with it. The only modern writer who disagrees with this theory is Verneuil, who believes that it is produced through muscular action. He claims that there is a paralysis of some of the muscles about the hip-joint and that their antagonists pull the head out of the acetabulum. This theory has no other supporters. Güterbock reported four cases, in 1874, occurring during the course of typhoid fever. These took place suddenly without any trauma, the only symptom of a joint affection having been pain in both hips. Verneuil, in 1883, reported six cases occurring during acute articular rheumatism. Delens added two to the list of spontaneous luxation of the hip, these occurring during typhoid. Sainton also reported a number of cases in 1892, and Champenois recently collected and published ten cases, all taking place during convalescence from typhoid fever. The right hip was most frequently affected. Kirmisson reduced a dislocation which occurred during acute articular rheumatism on the twelfth day in a girl 18 years of age, and also published a case in which the dislocation occurred during scarlatina. Phocas, in 1894, reported a typical case in which a dislocation of the hip occurred during convalescence from typhoid. The writer, in addition to the case reported, saw a double dislocation of the hip which had taken place spontaneously during scarlatina, at the clinic of Professor Lorenz in Vienna. The case observed was one of a girl 12 years old, who was admitted to the service of Dr. Sick in the Hamburg Hospital. During an attack of influenza a spontaneous backward dislocation had occurred. Six months after this happened

she was operated upon by Dr. Sick, who found the acetabulum filled by inflammatory tissue, the head of the femur and the acetabulum exactly corresponding in size. The capsule was almost completely destroyed. There was no osseous focus. The head was replaced after the acetabulum had been curetted to remove the inflammatory tissue which filled it. Recovery took place very slowly, the wound having suppurated. The occurrence of such a spontaneous dislocation during an attack of influenza would seem possible, since during this disease exudation into joints takes place, as Franke has recently reported. This is the first case in which such a dislocation has been observed during influenza, the other diseases in which it has occurred being scarlatina, typhoid and acute articular rheumatism.

DISCUSSION.

DR. M. L. HARRIS The question to be raised in most of these cases is whether we have to deal with an arthritis, or with a case of osteomyelitis. In the first place, these cases almost invariably occur during the developmental period, before complete growth is reached. The tendency of micro-organisms to localize themselves and develop in growing bone is well known. These cases of dislocation of the hip-joint occur more frequently in certain infectious diseases than in others. For instance, typhoid fever is a disease in which dislocation of this joint is apt to occur, and we know the typhoid bacillus in this disease can always be found in bony tissue. Other organisms are not so liable to locate themselves in bone, and in the diseases produced by them we do not have dislocations so often. In scarlet fever we frequently have effusion into the joint, but dislocation of it is comparative rare. Effusion into joints occurs in other infectious diseases, as in measles, mumps, dysentery and variola, but dislocations in those diseases, however, are very rare, showing that there must be something besides a synovitis to produce the dislocation. Crepitus has been observed, as in the case mentioned by Dr. Eisendrath, and when the joint was opened there was found erosion of the acetabulum, showing that there was osteomyelitis present. The great frequency with which the hip-joint is affected is another point in favor of osteomyelitis. As is well-known, the femur is the most common bone to be affected by osteomyelitis. In ordinary osteomyelitis from pyogenic infection the upper end of the femur and pelvic bone or hip-joint are affected many times to once of any other joint. To give an illustration, in twenty-two cases, by Müller, the hip-joint alone was affected sixteen times, the remaining six cases being distributed, showing the great frequency with which the hip is involved. Here it was found that the acetabulum was the part primarily affected in 25 per cent. of the cases. Another thing which points to the fact that these cases are probably osteomyelitis is the failure to reduce the dislocations and keep them so. In dislocations which follow typhoid fever reduction and retention have been very seldom accomplished. If we have a dislocation of an intact bone there is no reason why the reduced dislocation should not be retained. Ankylosis occurs quickly after these dislocations, much quicker than it does after traumatic dislocations, showing again disease of the osseous tissue. So I think the majority of these cases are not, strictly speaking, cases of synovitis but of the osteomyelitis, the infection extending secondarily to the synovial membrane.

DR. EISENDRATH (closing): I believe in a certain proportion of cases that the dislocation is due to a primary osteomyelitis rather than a primary synovitis. I do not know whether the cause of suppuration in this case was an infection from without, or from some osteomyelitic focus in the head of the bone, or whether it was due to the scarlatina through which the patient had passed four weeks previously. But there is one case recorded in which an abscess appeared at the popliteal space, that might possibly have been construed as an abscess which had come from a primary osteomyelitic focus. There are

undoubtedly cases where dislocation occurs as in articular rheumatism and scarlatina, where we have associated with it a primary synovitis and not osteomyelitis. In the case in which it occurred after influenza we could find no foci at the time. The true acetabulum was covered with inflammatory tissue; but the cartilage itself was eroded in a few places. There were no osseous lesions to be found.

EXHIBITION OF SPECIMENS.

DR. E. J. SENN exhibited specimens of *Pyosalpinx*, which were of particular interest because of their size and marked contortions. The specimen was from a woman 29 years of age, who had been married ten years, and had not given birth to any children. The trouble had existed for six years. The symptoms were those ordinarily present in such cases, with marked pains in the lumbar region of a decidedly intermittent character. There was a constant discharge of pus from the cervix uteri.

DR. WILLIAM HESSERT asked if the paroxysmal pains were followed by purulent discharge from the uterus.

DR. SENN—No; the discharge was constant.

DR. EMIL RIES called attention to the value of the specimens as examples of the contortions of the tubes as described by Freund, which he thought to be due to the rudimentary development of the tubes, the embryonal or infantile characteristics being preserved.

DR. JAMES B. HERRICK presented specimens from a case of

TYPHOID FEVER WITH FATAL INTESTINAL HEMORRHAGE
COMPLICATED BY ECTOPIC GESTATION.

The specimens were obtained from the body of a woman who had come to the County Hospital, Jan. 25, 1896, dying ten days later of acute anemia following intestinal hemorrhage. The anatomical diagnosis (Drs. L. Hektoen and F. Tice) was as follows:

1. Accidental Findings: Adherent pleuritis; healed pulmonary tuberculosis; adherent pericarditis; chronic endarteritis and valvular endocarditis; chronic nephritis; ureteral anomaly.

2. Typhoid fever: Splenic tumor, enlarged mesenteric glands, ulcers in ileum and colon, blood in cavity of intestines, typhoid bacilli in heart's blood, in spleen and kidney.

3. Ectopic Gestation: Uterus slightly enlarged, left tube normal, right tube to be traced for one-half its length; in median line of uterus and firmly united by adhesive bands to the uterus and to the neighboring intestinal coils, a gestational sac the size of a large cocoon and containing a mummified fetus, placental tissue and an old blood clot. Attention was called to two facts of interest in connection with the case:

1. The rarity of the combination of typhoid fever and ectopic pregnancy. A somewhat extended, though not yet completed, search through the medical indices had failed to show a previously recorded case of this kind. The case seemed to be unique. 2. The difficulty presented in diagnosis. The woman had given a history of an abortion at three months induced by the ingestion of drugs. Following the supposed abortion she had flowed for quite a number of days. Then there had developed a chill, headache, malaise, anorexia, fever. We were in the midst of an epidemic of typhoid. The question naturally arose whether the case was one of typhoid fever or of puerperal septicemia, the globular mass easily felt above the symphysis being taken for an enlarged uterus perhaps containing a dead fetus or undischarged secundines. The absence of local tenderness, of uterine discharge and of fetor, and the resemblance of the general symptoms to those of typhoid, lead to a policy of expectancy. This was rewarded in a few days by the appearance of rose spots, enlarged spleen and a fatal intestinal hemorrhage, making clear the diagnosis of typhoid fever. Even had the existence of extra-uterine pregnancy been made out during life, the question of infection through the uterus, or the infection

of the contents of the sac, would have arisen and would have rendered an early diagnosis a matter of extreme difficulty. A closer scrutiny of the history of the case in the light of the post-mortem findings, lead one to think that there had been a right tubal pregnancy with rupture about seven weeks prior to the patient's entrance into the hospital. For there is a somewhat indefinite account of abdominal pain at that time with some collapse or syncope.

DR. F. C. SCHAEFER presented a *Uterus with large Fibroid Tumor*, which had been removed by abdominal hysterectomy. The tumor was lobulated, weighing eight pounds. One lobe had filled the cul-de-sac of Douglas. The uterine canal was three inches deep. Patient did nicely after the operation.

DR. EMIL RIES exhibited a *Vermiform Appendix with a Fecal Stone* in its lumen, which had been removed by operation. The symptoms were peculiar in that inability to urinate was present from the onset. The diagnosis was made by the detection of swelling about the appendix by rectal examination.

DR. WELLER VAN HOOK referred to a similar case in which diagnosis of lead colic and renal calculus were successively made. The rectal examination finally cleared up the diagnosis.

SELECTIONS.

Glaucomatous Atrophy of Optic Discs in Syphilitic Patients Simulating Tabes.—Dr. Galezowski has addressed the Academy of Medicine of Paris on the above subject, as is reported in *Annales d'Oculistique*. Certain varieties of glaucomatous atrophy of the discs are frequently confused with ataxic atrophies. The following signs may help to avoid this error. If the affection is glaucomatous, then: 1. The disc is white, more especially on the external side. 2. The central veins of the optic nerve are diminished in size at their point of emergence, but after crossing with the central arteries, most frequently near the edge of the disc, they become larger. 3. Sub-cutaneous pulsation of the central artery is seen. 4. The pupil contracts to light, but it is enlarged and irregular. 5. The visual field is narrowed in the internal of supero-internal portion, while it remains normal at least for a long time in the external and inferior portion. 6. Dyschromatopsia does not exist at the beginning of the disease, and is hardly appreciable later when the opaque zone of the internal visual field has reached the central point of vision. 7. The patella reflexes are preserved and there are no shooting pains. The disease is of gouty, arthritic, or syphilitic origin. Repeated anterior sclerotomy and general treatment appropriate to the diathesis (gout, syphilis) considerably improve the atrophy of the disc and sometimes even arrest it, as I have found in five out of seven cases which have come under my observation.

Missed Labor.—The *British Medical Journal* quotes from an article by Stahl, in *Der Frauenarzt*, the history of a case in which he feels sure that labor was missed, and where he afterward induced a kind of secondary "premature labor," as he terms it, or, in more usual terms, he delivered a fetus which the uterus refused to expel. The patient was intelligent. Her pelvis was contracted by prominence of the sacrum. Three labors had been normal, and only lasted some two hours each: a fourth had been more lingering, and a very big child was delivered at term. Labor pains, very distinct, set in at term at the fifth pregnancy. For three hours the uterine contractions were strong and regular; then the intervals grew longer and the pains weaker until they ceased. When 302 days had elapsed after the last period, Stahl found the patient inconvenienced by the great size of the abdomen, so he turned and delivered a very well-developed fetus, which was alive at the beginning of the delivery. The prominent sacrum gave great trouble; the perineum was badly torn, owing to the great size of the fetal head; ossification of the cranial bones had ad-

vanced very far, and made the parts incompressible. The fetus weighed twelve pounds eight ounces, the placenta and membranes two pounds. The measurements of the head were: Circumference, 16 inches: occipito-frontal diameter, 5.8 inches; biparietal, 5.2 inches: bitemporal, 4.6 inches. The perineum and the rent, nearly an inch long, in the rectum were sewn up at once, and the mother made a good recovery. No uterine disease or rectal trouble ensued.

Morphologic Transformations in the White Corpuscles in the Blood Vessels.—Marquevitch has been studying the leucocytes in the active circulation during a series of interesting experiments. He prepared the animals (dogs) by the Pawlow method: Closing the long circuit by compressing the carotid and art. subclaviae (artificial respiration, on account of the interruption of the cerebral circulation) and also compression of the rising part of the aorta, with a direct communication between the right auricle and the left ventricle, by means of a glass tube between the art. subclavia dextra and the vena subclavia or jugularis sinistra. Ligature of the left vena subclavia below the entrance of the ductus thoracicus, with occasional ligature of vena cava inferior. In this way the blood practically made the short circuit only, and samples taken out of it at intervals of five, fifteen and thirty minutes, and one and two hours, were examined. The lymphocytes, small and large, were all counted with the polynuclear leucocytes. Marquevitch considers them all, with Ouskow, merely different forms of the same corpuscle: The "young," the "mature" and the "old." Counting showed that the young ones decreased in number, the mature ones increased slightly, although a part of them were changing simultaneously into polynuclear cells. The effect of artificial respiration with pure oxygen, and also of injections of tuberculin was to hasten the transformation of the mature cells into polynuclear ones, but warming the animal produced no appreciable effect. Chloroform arrested the transformation and diminished the number of leucocytes found, which Marquevitch ascribes to the accumulation of them in the capillaries of the lungs in consequence of the positive "chemo-tactic" effect of the chloroform.—*Centralblatt f. Phys.*, February 22.

Primary Sarcoma of the Pleura. It is a serious matter to announce the diagnosis of this disease, and yet absolute certainty is difficult to acquire. Guinea pigs inoculated with the fluid withdrawn from the pleura will determine whether it is a case of tuberculous pleurisy, which is often terminated by recovery. Another point of assistance in diagnosis is the absence of febrile conditions: sometimes there is hypothermia. The almost immediate reproduction of the effusion after the puncture is another characteristic symptom, as also the compression and the absence of marked modifications after puncture. As a consequence of the pressure in the thorax, some cases present a turgescence of the veins in the neck, arm and face, or an edematous appearance of that half of the thorax. Others experience a difficulty in swallowing, and others show a dilatation of the pupil on that side. The pain is also characteristic, diffused throughout the thorax, with increase on local pressure, and extending into the shoulder and arm. It is besides, more or less continuous. Palpation is also a most important guide in diagnosing, as several cases on record presented marked protuberances in the thoracic walls. The fluid withdrawn varies so much in different cases that it is not so much of an assistance as might be expected. The above points are culled from a long and analytic treatise on this subject in the *Progrès Médical*, January 4 and 18.

Latent Contagiousness in Certain Strictures of the Urethra. There are some physicians even now who still query whether gleet, or military gout as the French call it, is contagious. They should read an able article on this subject in the *Revue clin. d'And. et de Gyn.*, November, 1895, by Hamonic, and be convinced. He not only proves that a defined case is contagious,

but that many an unsuspected case is also. When an old case comes to consult us as to whether he can marry, a superficial examination is not enough: the urethra should be examined again and again, especially on waking in the morning, to discover the slightest trace of purulence, and a careful search should be made for any evidence of a stricture which may contain the pathologic germ latent in some form, and it should be scrupulously removed. By these precautions we will prevent the sad consequences to the young wife which occur again and again in practice, and which we are too apt to ascribe to the "changed conditions," fatigue, etc., instead of seeking their source in the latent poison in the husband. Hamonic describes a couple of most convincing cases in which the husband believed himself cured, but after a year the wife presents a typical purulent endometritis and secondary ovaro-salpingitis, and examination of the husband discloses a series of urethral strictures, with the presence of gonococci, which are also found in the lesions of the wife. In these cases the husband had been free from disease to all appearance for five years preceding his marriage, which demonstrates the necessity of the most rigid investigation before the physician approves of matrimony in such a case.

The Bicycle in Therapeutics.—Physicians are complaining that it is with the bicycle now as in the early days of electro-therapeutics, they are unable to order it with any degree of certainty, as there are as yet no terms of scientific measurement of speed, effort, resistance of the wind, etc. Moderation is the warning sounded by every physician who mentions the bicycle, and Villaret states that he would never venture to recommend it to an elderly person, who did not know how to ride it, on account of the danger from falls. A stationary bicycle for home exercise is now on the market. Heart troubles contraindicate the use of the machine and walking is much to be preferred in cases of fatty degeneration. But all agree that for a sound person the wheel is a fine recreation and exercise. Some firms supply their employés with wheels. The word "bike" can be considered a part of our language now, as the Queen has conferred the title of "sergeant bikeman" on the officer who has charge of the royal bicycles, and as the *Youth's Companion* remarks: "If Her Majesty is not an authority for the Queen's English, who is?" In Vienna no one is allowed on the public streets without a license, to obtain which he must pass an examination, riding between boards laid on the floor, without touching their edges, and dismounting at a word either right, left or backward.

Indications for Curettement of the Uterus, and Method of Procedure.

Where the placenta is retained, the first thing to be done is to arrest the hemorrhage and prevent infection. Sublimate in 1-1000 solution for the general irrigation, is the best for ordinary use, and if the hemorrhage persists, a 1-4000 solution can be used for an intrauterine injection, very hot, followed by the insertion of a dossil, first boiled in a solution of carbonate of soda. The inconveniences of this are counterbalanced by its effect, as its removal next day is often followed by expulsion of the placenta. Where these means are unsuccessful, curettement is indicated, although some, like Pinard, prefer continuous intrauterine irrigation. But this is almost impossible except in the hospital, or home of wealth. The placenta might be removed with the fingers, but it is often more difficult to insert the finger than the curette, which is more thorough in its work. Simple retention requires merely antiseptic precautionary treatment, but in retention with hemorrhage after abortion, and in cases where the fetus has putrefied, and portions are still left, and in all cases of septicemia with fever, chill and pains the curette is urgently called for, if the symptoms persist twenty four hours in spite of the intrauterine injections. There must be on hand a Sims' speculum, one or two bullet and other forceps, an intrauterine catheter, a sound

for the bladder, and curettes of several sizes, styles and scoops, Volkmann's and Recamier's preferred, scissors, razor, and everything carefully sterilized. As the operation is neither long nor painful, it is not necessary to resort to an anesthetic although ether can be given. The patient in the obstetric position, at right angles to the edge of the bed, her limbs held by assistants, the pelvis elevated, the vulva is shaved, washed and scrubbed with soap suds, the bladder is emptied and a vaginal injection made with an antiseptic solution. The neck is held with bullet forceps, and if not sufficiently dilated, this is completed with a Hegar bougie. The curette is then introduced and the entire inner surface of the uterus scraped, first the anterior wall, and then withdrawn to remove the detritus, after which it is reintroduced and the posterior wall scraped in the same way. A smaller curette is then taken and the whole surface gone over, until nothing but clots can be found anywhere in the uterus. The neck is then treated in the same way, after which an intrauterine injection is made. Then with long-bladed forceps a wad of cotton dipped in a 5 per cent. solution of phenic acid or 10 per cent. of chlorid of zinc, is used to wipe out the whole inner surface of the uterus. The uterus is closed with a tampon of iodoform gauze, with a drain; another antiseptic tampon is inserted in the vagina; the vulva is covered with a pad of cotton, and the patient replaced in bed. —*Gaz. Méd. de Liège*, March 12.

The Health of the German Army.—In the Budget Committee of the Reichstag, Staff-Surgeon-General Werner a few days ago laid before the members some very interesting statistics concerning the decline of disease in the German army. From these it appears that since the year 1868—counting up to 1894—the number of cases of all descriptions has gone down from 1,496 per 1,000 to 867 per 1,000, which means a reduction of 42 per cent. The death rate in the army was 6.9 per 1,000 in 1868; by 1894-95 it had gone down to 2.4 per 1,000, a reduction of 65 per cent., which means that about 2,200 more men are preserved to life every year. In the thirties of this century the death rate in the Prussian army was higher than the death rate of the male population between 20 and 30 years old (the numbers were respectively about 14 per 1,000 for the army and about 10 per 1,000 for the general population). The case is now reversed, for in 1893 the death rate of the male population of from 20 to 30 years old in Prussia was 6.38 per 1,000, and the death rate in the German army in the year 1892-93 was 3.0 per 1,000. This remarkable advance is due to modern hygiene, and the statistics show that above all it is the epidemics that have lost ground. Smallpox is now exceedingly rare, and has caused only two deaths since 1873. Dysentery has been reduced from 6.8 per 1,000 in 1873-74 to 0.39 per 1,000 in 1893-94; that is a reduction of 94 per cent. As for typhoid, the prevalence of which is considered to a certain extent the measure of the healthy condition of an army, in 1868 the number of cases was 33.8 per 1,000, and in 1893-94 only 2.4 per 1,000; the death rate from typhoid was 2.2 per 1,000 in 1868, and in 1893-94 it had gone down to 0.21 per 1,000, a reduction of about 90 per cent. Malaria showed 27.6 cases per 1,000 in 1868, and in 1893 even 54.5 per 1,000; in 1893-94 only 0.81 per 1,000. Contagious eye inflammation has gone down from 7.0 per 1,000 to 1.5 per 1,000 in a similar period of time. The campaign of 1870-71 was the first exception to the time-honored rule that more fighters are carried off by disease than by the enemy. Of the German army 26,562 men (33.7 per 1,000 of the total number) fell in battle, and only 14,618 (18.6 per 1,000) by disease. The Germans were not without typhoid and dysentery epidemics, but the most devastating war epidemic, smallpox, scarcely affected them. There were not 300 deaths from smallpox on the German side during the war, while in the French lines there were 23,400 deaths from smallpox. There can be no doubt that the immunity of the Germans was due to the vaccination so strictly enforced in the German armies during thirty previous years of peace. Dr. Werner further stated during the war the French prisoners of war brought smallpox into Germany, and that the epidemic spread and carried off a greater number than the campaign itself. Some disease statistics from the Russo-Turkish war of 1877-78 were also given showing that in this campaign the old rule held good, as the number of deaths caused by disease was far greater than the number of deaths caused by the enemy. —*British Medical Journal*, February 29.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.
W. H. LOWDERMILK & CO., WASHINGTON AGENT.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

SATURDAY, APRIL 4, 1896.

THE POWER AND FORCE OF A UNITED
PROFESSION.

Every intelligent and reflecting physician must recognize the power and force of the medical profession of this country when united in an effort to accomplish such legislation as may be deemed conducive to public welfare and to the advancement of scientific medicine. This has been so often demonstrated that it must be accepted as a settled conviction. But conviction of such a fact does not carry with it the accomplishment of a result without united and concerted effort. Therein lies the failure of attempts to secure favorable legislation in many instances. Even worse, the lack of interest and united effort has quite frequently permitted adverse legislation that has trammelled the progress and limited the beneficence of a life-saving science.

There are now pending in Congress two bills, which if enacted into laws will be limited in their operation to the territorial area of the District of Columbia, with a population of two hundred and seventy thousand people, but the significance of such legislation by the congress of the United States, the highest tribunal of legislation in the country, will be far reaching.

The passage of the bill relating to the testimony of physicians in the courts of law will establish the principle of privileged communications to physicians, and add such force to it that every State in the union will probably accept by statute law the justice and wisdom of such protection of its citizens from the compulsory disclosure in open court of such confidential communication to physicians. The enactment of the pending bill by Congress would seem then to be the key-note of success in those States and Territories in

which the liberty of privileged communications to physicians has not been extended to their citizens.

The other bill has for its object the prohibition of vivisection, and will, if passed, close the laboratories of the Surgeon General's Department of the Army; the Marine Hospital Service and the Bureau of Animal Industry of the Department of Agriculture, and all medical college physiologic laboratories in the District. Such will be its immediate effects, but its significance is so wide-spread in disastrous suggestion that the Humane Societies in every State, city and town throughout the land will seize it as the expression of popular judgment, and upon that basis will appeal to the State legislatures for similar statutory prohibition. Will the profession wait until the crisis comes? Will it rest supinely in fancied security until defeat and disaster are impending, or will it assert the prerogatives of scientific medicine, and by united effort enforce them in the interest of, and for the welfare of mankind, in that governors, legislative bodies, town councils and all others in authority may come to know that in preventive and remedial medicine truth and science must dominate fanaticism, whim, caprice, charlatany and mercenary adventure.

IMPROVED SANITARY AND SOCIAL CONDITIONS OF
THE SEMINOLES OF FLORIDA.

JACOB E. BRECHT, M.D., of Fort Myers, Florida, is superintendent of the Indians of that State, and is now engaged in securing by purchase lands for the individual ownership of his charges. An appropriation of \$3,000 per annum given by the Federal Government for the Seminoles is applied to this purpose. Heretofore, these Indians have been homeless, so far as the ownership of land has been concerned. These Indians are a cleanly, healthful and thoroughly peaceful people. They are a truth-loving class, and in fact claim that before the white man came, they did not know how to lie, but since they taught them how, he once in a great while resorts to deception, though liars among them are held in utter contempt. Their women are the purest of the pure. A whole realm can not change them from the path of virtue. Lewdness is an unknown sin. They seldom commit crime, and their only punishment for it is ostracism. They are compelled upon pain of death to leave the village and must stay away a period of years. They usually hang around other villages, and if they once succeed in getting into the "green corn dance" their social position becomes reestablished. Murder and wife-beating are the worst of the crimes. Wife-beating is not tolerated.

The Indians are becoming more prosperous every year. Some of them have a few thousand dollars saved up, and a few have houses of two stories. These houses are picturesque. Their roofs are of palmetto thatch. The house is of boards, usually supplied by

the Government saw mill. This mill is run in connection with an industrial school. The school is not largely attended, because of the prejudice among them against the Government. They are not increasing in population very rapidly, which fact is referable to physiologic and social causes. There has, however, been an appreciable increase. In 1859 there were but 112; now they are something over 500. The chief social reason for their slow propagation is the custom of countenancing no marriage of persons who have a drop of the same blood in their veins. This is sometimes hard on the girls. One leader has two beautiful daughters who can not get married because the eligible young men are almost all akin to them. Very often the custom causes strange alliances, and there has been a number of instances where young bucks of twenty have squaws of sixty. The reason for a lack of increase is the dearth of knowledge on the part of men and women of physiology and hygiene. The mothers, although intensely fond of their offspring, will allow them to stuff themselves with food and indigestible substances in the shape of sand, charcoal and clay. Many deaths occur during the first three years. "If a child lives to be five, you can't kill him with a lightwood knot." If the parents knew more of diet the race would rapidly increase, for a stronger, sounder people are not to be found on the earth.

Of the adjustment of their marital relations, DR. BRECHT says. "The wife is proud of the husband, and the husband considerate of the wife. He hoes in the field and hunts and fishes, while she attends to the household duties and tans the hides and cures the bird skins and plumes. The braves are splendid hunters. They know the habits of every fowl and animal, and can mimic their notes with absolute accuracy. They are not long shots, preferring to make sure of their game by creeping upon it. They can advance to within a few feet of deer. There are now three settlements of Indians: One at Miami, under Tommy Tiger Tail; another at Cow Creek, under Tallahassee, or Old Tony; and the third in the Big Cypress, under Dr. Tommy. Dr. Tommy is leader-in-chief of the tribe, and the others are sub-leaders. None of the three is a chief. In recent years, or since they have taken to peaceful vocations, there have been no chiefs.

They have a religion. They say that the white man's God is the same as their God. The Father they call "Fanshockohomachey," and the Son "Chockatomassee." They believe that there is a future state, but call death "the big sleep." They think that Christ's coming took place in Georgia, and that a great assemblage came to a mountain to hear Him. The mountain split in twain, and one people slid northward and the other southward. They do not pray, but, as they express it, think with God.

THE CASE OF MEDICAL INSPECTOR KERSHNER OF THE NAVY.

On March 19 this *cause célèbre* of the navy was brought to a close, so far as Executive action is concerned, by the promulgation of the fact that the President had approved the sentence of the court-martial in this officer's case.

As ten months have elapsed since the adjournment of the court (May, 1895), a brief reference to the circumstances may be necessary to acquaint the profession with the main facts of a trial that will take its place in the annals of naval jurisprudence as one of its most memorable occurrences. It is stated by the Washington correspondents of the public journals that the long delay in approving the sentence of the court was due to the desire of the President to thoroughly acquaint himself with the evidence and his reluctance to carry into effect so severe a penalty. The long service of Medical Inspector KERSHNER, who entered the navy in 1861 from the State of Maryland, his high professional standing, his distinguished war record and his nearly twenty years of duty afloat, made the charges almost incredible, and his friends and professional associates are still loath to believe that his offense was other than a technical violation of regulations and a subsequent unintentional error of judgment. DR. KERSHNER has always been a stanch outspoken upholder of the rights and dignities of the medical corps and his friends believe that his insistence on his prerogatives as the senior medical officer of the vessel to which he was attached, incurred for him the hostility of the line officers as far back as January, 1894, when he urged that the hospital on board the *New York* should be shifted from the objectionable site in the extreme bow of the vessel to a commodious, well ventilated location on the gun-deck as on board foreign men-of-war of the same type. Subsequent disagreements as to the proper care and transportation of patients, control of subordinates in the medical department, potability of water supplies, etc., are alleged to have intensified an antagonism, which culminated in DR. KERSHNER's objection to sending an assistant-surgeon on board a British merchant vessel anchored near the flag-ship on the ground of the possible hazard from unnecessary exposure of the crew of the latter during the prevalence of yellow fever and the further fact that medical assistance from shore was readily obtainable. With many other American naval medical officers, DR. KERSHNER had had frequent experiences of the demands by British merchant captains for such service from the medical officers of neighboring American men-of-war, which whenever possible have been rendered gratuitously, although there is good reason to believe they appeared as substantial charges against the owners. Notwithstanding the fleet-surgeon's objection, a medical officer was ordered to make

the visit with the discovery that the case was trivial. The admiral thereupon reported the matter to the Navy Department with a very harsh arraignment of DR. KERSHNER as incompetent and the expression of his desire that another medical officer might be detailed in his stead. For these intemperate expressions he is said to have been sharply rebuked by the Department, and this would probably have been the end of the matter, had not a detailed statement of the affair appeared in a New York daily paper, upon which the Admiral instituted a court of inquiry to discover who had divulged the information on which the publication was based in violation of a regulation of the department forbidding such disclosures by officers of the navy. It was charged that DR. KERSHNER had at first emphatically denied having made such a disclosure to any one, but subsequently corrected his statement to the effect that he had not sent verbatim copies of the papers in the case to any one, but admitted that he had sent abstracts to the Surgeon-General of the Navy as head of his corps and to his old friend, Medical Director DELAVAN BLOODGOOD on the retired list; whereupon he was brought before a general court-martial for having, first, violated a regulation of the navy forbidding such unauthorized communications by officers, and, second, for having committed perjury in having sworn, in the first instance, to tell the truth, "the whole truth and nothing but the truth," which his subsequent correction, it was alleged, was evidence he had not done. It is significant, in this connection, to note that ADMIRAL MEADE himself was credited, not long after, with having committed a similar breach of regulations in a published interview with a newspaper attaché, which he declined to affirm or deny. Had DR. KERSHNER been equally prudent and reticent, he would probably have escaped with a reprimand for the violation of regulation with which he was charged. That DR. KERSHNER willfully committed perjury, his associates during his thirty-five years' service in the navy, both of the line and staff, are not disposed to admit. He is a prominent member of the New York Commandery of the Military Order of the Loyal Legion of the United States, and one of the oldest members of the Union League Club of New York, where undiminished confidence in his integrity is entertained, a feeling shared by his fellow professors in the Post-graduate School of New York. In view of DR. KERSHNER's long and faithful service, it is a matter of regret that the President was not able to see his way clear, as he would doubtless have been very glad to do, to a mitigation of the severe penalty for the violation of a regulation, committed under the sting of the contumelious comments of ADMIRAL MEADE, and the misapprehension which led to the apparent evasion before the court of inquiry.

This incident shows the necessity for such an absolute definition of the military status and office of the

navy medical officer, as governs the army medical officer, that an earnest, enthusiastic and sensitive officer, as DR. KERSHNER is represented to be by his friends and associates, keenly zealous for the care of the sick and well for whom he is responsible, shall not be led, in the conscientious performance of his duties as physician and sanitary officer, to incur the undisguised hostility of the officers of another corps.

POPULAR LUNACY.

In one of EDGAR A. POE's stories there is given an account of a visit to a lunatic asylum, where the patients had turned the tables on their keepers and were running the establishment according to their own mentally vagarious notions. One of them, an exceedingly conscientious young female, had gotten the idea that the wearing of clothing was highly immodest and immoral and proposed therefore to return to her birthday costume or that originally the fashion in Eden. It was, however, considered even by her fellow lunatics an evidence of insanity and she was restrained from imitating too closely her mother Eve, in her state of primal innocence.

A case that has recently created quite a stir in Great Britain suggests POE's story in one or two of its details. A young woman, highly educated and of good social position, and of good prior reputation, suddenly asserted her conviction that marriage is immoral and her intention to at once go and live in concubinage with a workingman. She was declared insane by an eminent authority, but from here on, the case differs from the story: the public was not as discerning or as decent as the lunatics; the socialists, MR. JOHN BURNS at their head, took up her defense, and the Commissioners in Lunacy, presumably at their instance, examined her and discharged her from custody, it is said, as not presenting any definite type of insanity. The examination was brief, only one hour is said to have been consumed, and the suspicion that it was imperfect and the resulting action stimulated by the clamor of the lady's socialist supporters is rather justified than otherwise.

Whatever may have been the actual condition of the woman the moral of the decision is this: Insanity must be of a definite type, no new forms are to be discovered, our knowledge of it is exhaustive. This is an opinion that, however satisfactory it may be to the legal mind, can have no medical standing whatever, its mere statement is a *reductio ad absurdum* in itself. Again it is a claim that two officials can in an hour obtain a better insight into a case than an expert and a family physician with full knowledge and continuous observation. The only alternative to these suppositions is the assumption that the commissioners acted under the influence of a popular prejudice and were guilty of releasing a probable lunatic to disgrace herself and her family without complete and full

investigation or examination. The case at best leads to rather unsatisfactory conclusions as to the absolute perfection of the English lunacy methods.

There is still another point which it strongly emphasizes, namely, that no matter how absurd or outrageous an individual may act, the popular prejudice against the restriction of his or her liberty on the ground of insanity can be made effective on almost any pretext. The public *en masse* is not a rational being under such circumstances and mob law and its equivalents are as ready to release inconvenient lunatics at some times as they are to hang them at others. There is no other subject in regard to which public opinion and the lay press takes more opposed and irrational views, than that of insanity, and there is hardly another subject on which the judge-made law is more inconsistent. Whether there will ever be any perfect popular enlightenment on this subject is perhaps a question, it is too much to expect even if individuals are well informed, that acting collectively they will ever be altogether rational in their behavior, and insanity is certainly one of the subjects upon which the *vox populi* becomes too often the *vox diaboli* more than anything else.

It is especially unfortunate when individuals or bodies acting in a judicial capacity are influenced by such misguided public clamor or find it necessary or expedient to give way to it, as it can only cause infinite distress to innocent persons and tends to no public good.

NEW YORK OFFICERS AT VARIANCE OVER THE CLOTHING OF INSANE PATIENTS.

A disagreement has arisen between the New York State Commission in Lunacy and the Charity Commissioners of New York City regarding the clothing of the insane to be taken charge of by the former board in the Manhattan State Hospital. The latter board is litigating the question of providing new suits of clothes for the lunatics transferred by it to that hospital. Dr. C. F. Macdonald, of the State Commission, defends the exaction of new clothing as follows:

1. To reduce, as far as practicable, the danger of introducing contagious or infectious diseases into the institutions which were then sheltering about 13,000 patients, coming from all the walks of life and in widely different conditions of physical and mental debility, beside some 2,000 employes and over 100 officers, while the yearly admissions of new cases exceeded 2,000.

2. To put a stop to a then prevalent practice among county authorities of sending to State hospitals patients clad in filthy, ragged and worn out clothing, which had to be discarded and often destroyed altogether, before the patient could be safely received in the wards.

It is notorious that the germs of such diseases have been introduced in this way into hospitals, and have there caused serious and in some cases fatal results. This danger is especially present and potential in the case of vagrants or tramps, or the outcasts of cities, who become insane. In order to guard against epidemics and protect the health and lives of these thousands

of peculiarly susceptible persons, it was felt to be indispensable that the clothing should be new and not merely clean, but it was not insisted that it should be of a high grade. From a wide range of inquiries it was found that the average cost of sufficient clothing suited to the different seasons of the year need not exceed \$10 per capita. Had the rule prescribed clothing, not new but simply "comfortable," it would have opened the way for continual bickering over the question of what in any case could be accepted as "comfortable."

If the decision of the Supreme Court, which will be appealed, be sustained, its effects will be most lamentable, since it will largely impair, if not render useless, an important safeguard erected in defense of health and safety for the insane inmates of State hospitals, now exceeding 19,000, beside several thousands of officers, attendants, nurses and other employes. An appeal will be taken, and a stay of judgment be sought, since the effect of the order is not confined to the one locality of New York city, but extends over the entire State. Meanwhile the Commission's order will be maintained until the question is finally settled by the court of appeals.

Aside from the harmful effect of the action of the charities commissioners in its bearing upon the patients of the Manhattan State Hospital, and upon those in other State hospitals, it is not conducive to the financial interest of the city of New York, since the yearly cost of new clothing if provided by the city for each of its insane when sent to the hospital, would not at a liberal estimate exceed \$20,000, while if the State has to provide clothing in advance and pay for it out of the State treasury, the city's share of such cost, being based on its assessed valuation, would reach close upon \$25,000.

THE JOURNAL SPECIAL TRAIN

Will leave the Central Station at Twelfth street and Park Row, Chicago, via the Big Four Route, at 12 o'clock Sunday, May 3, arriving Indianapolis 6:10 P.M., there to be joined by parties from Peoria, St. Louis and the west; arriving Cincinnati 9:05 P.M., Chattanooga 9:30 A.M. May 4, and Atlanta 3:10 P.M. the same day. Sleeping car accommodations will be provided at the following rates: Lower berths, Chicago to Atlanta, \$4.50; full section, \$9. Detailed information may be obtained from this office.

CORRESPONDENCE.

American Ophthalmologists Not Ashamed of Their Work.

DENVER, COLO., March 25, 1896.

To the Editor: The JOURNAL for the 21st inst., under the heading, "Ashamed of What They Should be Proudest of," contains an indictment of American ophthalmologists that must not pass unnoticed. The allegation that the American ophthalmologist obsequiously suppresses his own best work, on refraction and muscle balance, to court the favor of the "foreign distributor of distinction," is not sustained by the facts.

To require in medical literature that the number of papers upon each subject should be proportioned to the number of cases of the kind met with in everyday practice, would be to make it a dreary waste of profitless repetition and unsuggestive detail about minor ailments. But even by this standard the Transactions of the American Ophthalmological Society for 1895, which furnished the occasion for the attack, have been misrepresented. The Transactions contain the following papers relating to refraction and the ocular muscles: Report on Six Hundred

and Twelve Cases of Convergent Squint, with Final Results of Operation; Amblyopia ex Anopsia; Recurrent Oculo-motor Palsy; Variations in the Power and in the Astigmatism of Thin Lenses in Oblique Central Refraction; Four Thousand Cases of Ocular Headache and the Different States of Refraction Connected Therewith; The Use of Strychnin in Insufficiency of the Interni; and a Note Concerning the Lens in the Eyes of Rodents. And these papers with the discussions upon them occupy 84 of the 214 pages of the transactions in question.

In the recent volume of the Transactions of the Section on Ophthalmology of the AMERICAN MEDICAL ASSOCIATION papers and discussions on similar subjects occupy 150 out of 350 pages, almost exactly the same proportion. But perhaps this charge of a lack on the part of American ophthalmologists of a proper respect for this part of their work, or of fear to avow it before European critics, is most completely met by the Transactions of the last International Ophthalmological Congress, held in Edinburgh. Of the ten papers of American authorship therein contained five are concerned with anomalies of refraction and muscle balance, and in the discussions on such subjects the small number of Americans present furnished two-thirds of the speakers.

The attack in question is equally uncalled for and unjustified whether it be regarded as against American ophthalmologists, or as against the American Ophthalmological Society, the only important rival of the Section on Ophthalmology of the AMERICAN MEDICAL ASSOCIATION. One who has read the papers mentioned, and who can understand them, will recognize such expressions as "travesty of medical progress," or "caricature of conservatism," as inapplicable and absurd.

Of course it is impossible for one editor to prepare all the editorial columns of our great medical weekly, and I feel sure that you will not knowingly allow the use of those columns for the expression of private spleen or personal disappointment.

Cordially yours,

EDWARD JACKSON.

Reply to the Article on Treatment of Aural Catarrh in the London Central Throat, Nose and Ear Hospital.

To the Editor:—In No. 9, p. 411, of this JOURNAL there is an article on "The Treatment of Aural Catarrh in the London Central Throat, Nose and Ear Hospital," that is liable to do harm, since it fortifies the position of the routinist, by allowing him to creep behind the walls of a large hospital. This article being typical of the standpoint of a great many physicians it would be treachery to let it pass without criticism.

Its author says: "I shall now proceed to make clear the method used for the cure of those varieties of ear disease, usually termed catarrh, and divided into acute non-suppurative, acute suppurative, chronic non-suppurative and chronic suppurative." Here the doctor undoubtedly speaks of the greatest number of those diseases that have their seat behind the drum, that is, in the middle and inner ear, and calls them "catarrh." What does that word catarrh mean? Where is the line clinically? Would it not be better to talk first about an accurate diagnosis? The writer speaks about the methods of "curing" them. When there is necrosis of the ossicles, or of the walls of the tympanic cavity, which I know from other men of this school are classed under the head of chronic suppurative catarrh, or when there are adhesions of the ossicles to those walls, which very often exist in those cases that they call chronic non-suppurative catarrh, did ever anybody see cures from the methods indicated? Cure means restoring, at least partly, normal and anatomical conditions and functions. It is not the purpose of these lines to show another way to reach that aim. For this there are text-books and papers, but I wish only to state that the way the article indicates will mislead.

The article correctly classes together acute suppurative and non-suppurative forms, but not because the one is a more severe form of the other. The reason for classing them together is that they are alike, the only difference being a perforation of the drum in one case, where this membrane is not so thick and offers less resistance. Pus is present in all ears afflicted with acute otitis media, as Bezold, Gradenigo and Knapp proved long ago.

The statement about adenoids is a matter of course, but I am thankful to the writer for giving this disease the place that is due to it. The subject of adenoids is not a fad of the specialists that will disappear again; but its high influence on the general condition, as well as on the special condition, of the surrounding organs, especially the ear, can not be overestimated. Because their removal is a nice and easy operation is not a reason why we should neglect it.

The paragraphs on chronic suppurative and non-suppurative catarrh have again the marks of routine treatment. I do not understand why, if such routine is adequate, those practical Englishmen should take doctors for such cures instead of nurses or intelligent waiters.

I think that the London Throat, Nose and Ear Hospital does not any longer occupy that standpoint. The days of the routinist in medicine are past: let them be past in otology, too. Let us start the reformation, however, in our own neighborhood. Let us instead study the conditions of each single case, then give it proper attention, and thus deserve the name of doctors and not treatment manufacturers.

DR. J. HOLINGER,

Lecturer Post-Graduate Medical School; late Assistant Illinois Eye and Ear Infirmary.

Death from Antitoxin.

WHEELERSBURG, OHIO, March 27, 1896.

To the Editor: A most unfortunate and distressing accident occurred in the practice of Dr. S. S. Halderman, of Portsmouth, Ohio, on March 22, in connection with the use of antitoxin. A mild form of diphtheria was prevailing in the family of Mr. George Krickler, cashier of the Central Savings Bank, and the doctor administered the usual dose of antitoxin, as a prophylactic, to a little boy, 5 years old, in whom the disease had not yet appeared. The child, which had seemed to be in perfect health up to this time, was asleep when the injection was given, and in five minutes was a corpse. The doctor had withdrawn to another room to refill his syringe for use on another child, when the mother noticed the boy's lips puffing up and called to him that something was wrong with Willie. By the time the doctor reached the child, breathing had ceased. The killing fluid which thus acted with far more rapidity than a fatal dose of morphia, arsenic or strychnia given per mouth would have done, seems to have caused death by paralyzing the heart. At least that is the cause assigned in the death certificate. The serum was Behring's, fresh, injected beneath the scapula and in the usual way. The doctor, one of the first to introduce antitoxin into medical practice in Portsmouth, was an enthusiastic advocate of serum therapy, and presumably used all the precautions which skill and experience can suggest. This terrible accident, therefore, can have but one meaning. It furnishes absolute proof of the inherent danger of antitoxin as a therapeutic agent.

Cautious scientific observers have insisted from the outset that a substance capable of acting on the economy with the alleged effects of antitoxin must necessarily be a powerful agent. Hence many conservative physicians have hesitated to employ the new remedy. The older men remember aside from the new fads which have been constantly coming up—how it was with chloroform forty years ago. The highest medical authorities then insisted that it was perfectly safe when

administered with proper precautions. It was reported to have been used in 25,000 cases in the Crimean war and in 9,000 cases in St. Bartholomew's Hospital, without a single accident. Standard medical works sanctioned these reports. And no one will ever know how many deaths resulted from the recklessness engendered in the medical profession by this false attitude of the enthusiastic believers in chloroform.

So with antitoxin. Whatever may be the final verdict of the profession as to its merits as a remedy in diphtheria, the fact should not be lost sight of that it is a most powerful agent, that the contraindications to its use are not yet well ascertained, and that it can be an active instrument of great evil as well as possible good. It is not often that the evidence of the ill effects of an alleged remedy is as clear as it is in this case. Given as a prophylactic to a healthy child, disease can not be credited with any share of the result. No one can doubt that antitoxin kills, and that, too, right speedily.

JAMES L. TAYLOR, M.D.

The A. M. A. Badge.

WILMORE, PA., March 25, 1896.

To the Editor: In a late number of the JOURNAL my attention was called to an article written by Dr. Stewart, of Detroit, Mich., as regards a permanent badge for the AMERICAN MEDICAL ASSOCIATION. The article comes in a good time and I have often wondered that as yet nothing has been done through the JOURNAL, or at the yearly meetings of the Society, in the matter of choosing a badge for the Society, and am glad to see that Dr. Stewart has at last placed the matter so clearly before us as a Society. We surely know that the AMERICAN MEDICAL ASSOCIATION has been founded nearly a half century and can venture on a badge when every order or society, great or small, from the Masons down, are well known and readily distinguished by a badge. And it appears to me there would be no better time to decide on this matter than at the meeting at Atlanta, placing the matter in the hands of a committee with instructions that the badge shall be ready to issue at the fiftieth meeting of the ASSOCIATION, which will occur in 1897; and by the way, has there been any movement as yet to decide whether or not the Society shall hold its fiftieth meeting at Philadelphia, the place of its birth? It would be appropriate to do so in many ways, and would be the means of bringing a large number of members to the city and no doubt at the same time adding a large number of new members. Let us hear from other members on this matter of badges.

IRVING C. BLAISDELL, M.D.

Medical and Surgical History of the War.

To the Editor: Has there been a law passed for printing a new revision on the Medical and Surgical History of the War of the Rebellion which are to be distributed among the profession through the Congressmen in their districts? The Indiana State Board of Health moved for this bill for a new edition at their last meeting.

H. G. GRAHAM.

ANSWER: The work has not been republished.

BOOK NOTICES.

Treatise on the Diseases of Infancy and Childhood. By J. LEWIS SMITH, M.D., Clinical Professor of Diseases of Children in the Bellevue Hospital Medical College, New York. New (8th) edition, thoroughly revised and rewritten and much enlarged. Handsome octavo of 983 pages, with 273 illustrations and 4 full page plates. Cloth, \$4.50; leather, \$5.50. Lea Brothers & Co., New York and Philadelphia. 1896.

For more than a quarter of a century Smith's diseases of children has been a standard book of reference, and a textbook. In advanced age, and with ripened judgment, the distinguished author has revised the book, and this eighth edition

the reader will find quite up to date. Dr. Smith has always been a safe counselor and a conservative one. This characteristic is as apparent now as in the early editions. In regard to the Roux antitoxin treatment of diphtheria, after mentioning the established remedies, he says: "The remedies which we have mentioned are in my opinion the most efficacious and safest of those which pharmacy has heretofore furnished, but a new remedy, known as 'antitoxin,' has been so highly extolled by many eminent physicians as a remedy for diphtheria, that this new remedy demands attention if not employment, wherever this fatal malady occurs." The author then quotes at length from Roux's paper at the Buda-Pesth Congress, and gives his statistics. He quotes, p. 378, the favoring statistics of Saw, Turner, Widehofer and Caille, and *per contra* says: "We can not write so favorably of the use of antitoxin serum in the New York Foundling Asylum. Since a reliable preparation was obtained from the Health Board, 31 cases were inoculated with the serum. The number of units employed varied from 500 to 2,200. The antitoxin was inserted under the skin on the first day in 12 cases, on the second or third day in 17 cases, and on the fourth or fifth day in 2 cases. Nineteen received the antitoxin once, 9 received it twice and 3 three times. Microscopic examinations revealed the Klebs-Löffler bacillus in all the cases, and the streptococcus in nearly all the cases, so that in all or nearly all the infection was a mixed one. The physicians who observed these cases and witnessed the necropsies and microscopic investigations could not resist the conviction that the broncho-pneumonia of which so many died was due to the streptococcus which was abundant in the lobules, and upon which microbe the antitoxin has little or no effect. Results: Recovered 14, died 17 (14 from broncho-pneumonia and croup). In four or five of the cases the benefit was very marked after the use of the antitoxin. It is seen that statistics thus far are favorable for the antitoxin treatment, but it must be recollected that the type of the microbe disease frequently changes, so that the experience of several years is often necessary to determine the full value of a remedy."

In regard to the treatment of typhoid fever the author holds that it can not be abridged or its course materially changed, and naturally the antiseptic treatment receives little notice. It is curious to see the term "scrofula" still retained in a chapter entirely separated from tuberculosis, but we suppose some vestiges of the past must be retained.

The surgical diseases of children are treated of by Prof. Stephen Smith with the well-known ability of that author, and brought up to date.

A Text-Book upon the Pathogenic Bacteria, for Students of Medicine and Physicians. By JOSEPH MCFARLAND, M.D., Demonstrator of Pathological Histology, Lecturer on Bacteriology in the Medical Department of the University of Pennsylvania, etc. With 113 illustrations. Cloth, 8vo, pp. 359. Price \$2.50. Philadelphia: W. B. Saunders & Co. Chicago: W. T. Keener, Agent. 1896.

This book, which is well illustrated and carefully printed, is an excellent one; indeed, we can not too strongly commend it. The description of the methods of study of the pathogenic bacteria are set forth with such clearness that even the beginner may feel less reluctance to commence the study of a branch of medical science which has hitherto been considered as a bugbear on account of the difficult technique. There is a vast amount of information, and yet the work is not bulky and there is no mere padding. We might criticise some of the inaccuracies in the historical introductory, but they are not material, as the work is in itself so useful and generally worthy of commendation. In the first place Redi's books, "Generatorem Insectorum," "De Ave Diomedea," "Experimenta circa varias Res Naturales," were published in one 18mo volume, Amsterdam, in 1686. The "experimenta naturalia" were made in 1662. In the frontispiece to the "De Insectis," a female

figure is seen seated at a table with her left hand resting on an open book, a scroll open before her, while with the right hand she is *adjusting the ocular of a microscope*, which is mounted on a tripod. In the frontispiece to the "Experimenta Naturalia," there is also a female figure, with a microscope, and an African presenting her with an egg, presumably that of a serpent. The name is "Franciscus" not "Francesco." We must take exception to the statement quoted from Agnew, that John Colbach, 1704, was the first to whom the "seminal thought of antiseptic surgery" may be traced. Theodorico of Bologna, about 1260 (d. 1298), distinctly taught that suppuration in wounds was a *pathologic* condition, due to prolonged exposure to the air, and he treated wounds with hot wine fomentations (dilute alcohol), in which he was followed by Henri de Mondeville, who, according to Nicaise, was a pronounced adherent of Theodorico's doctrine, and so taught in 1306. De Mondeville placed the lips of the wound in contact, after suppressing hemorrhage, and applied an antiseptic plaster, in which turpentine, resin and wax were the chief ingredients (for the avowed purpose of keeping out the air), over that he applied the hot wine-soaked dressings after the manner of Theodorico.

But we would not have our reader infer that Dr. McFarland's book is at all singular in its statements about the origin of the crusade against suppuration in wounds, and we have only adverted to it, in order to assist in setting right some prevailing errors in medical history.

Infantile Mortality during Child-Birth and Its Prevention. By A. BROTHERS, B.S., M.D. Visiting Gynecologist to Beth Israel Hospital, New York, etc. William Furness Jenks Prize Essay of the College of Physicians of Philadelphia. Cloth, 8vo, pp. 176, price \$1.50. Philadelphia: P. Blackiston, Son & Co. Chicago: The W. T. Keener Co., Agents. 1896.

No one can read this monograph without coming to the conviction that the prize was worthily bestowed. The work, while mainly a compilation, shows such judicious and thorough gleaning in the field of medical literature, that nearly everything of value on the subject will be found. There are thirty-eight chapters in which the various causes of infantile mortality are fully discussed. The arrangement is logical, and it will be a very welcome addition to the library of the general practitioner, the obstetrician and the student.

ASSOCIATION NEWS.

Excursion Rates to Atlanta.—All railroads except those west of the Mississippi River have now granted the excursion rate of one fare and one-third. All who wish to avail themselves of the reduced rates must pay full fare to Atlanta. When starting, take the certificate of the agent at the place. This certificate, when signed at Atlanta, enables the owner to buy a return ticket at one-third fare.

PUBLIC HEALTH.

Treatment for Venereal Diseases Provided.—A law was passed in Massachusetts in 1895 requiring that every city in that State shall provide for the treatment, either in a hospital or as outpatients, of indigent persons suffering from contagious or infectious venereal diseases.

Trichophytosis.—The report of the Bordeaux *Clinic* for dermatology, mentions several cases of genito-crural trichophytosis infected from cats, and refers to an epidemic of this disease in a large institution there, where several hundred students were affected at once, the infection probably being communicated by the riding suits worn in turn by the lads.

Must not Feed Garbage.—Whoever knowingly feeds or has in his possession with intent to feed to any food animal, except

swine, any garbage, refuse or offal collected by any city of more than thirty thousand inhabitants, by contract or otherwise, it was enacted in Massachusetts in 1895, shall be punished by imprisonment in the jail or house of correction not exceeding thirty days, or by fine not exceeding fifty dollars.

Maine's Candy Law.—A law was passed in Maine in 1895 forbidding the manufacture for sale, or knowingly selling or offering to sell, any candy adulterated by the admixture of terra alba, barytes, talc, or any other mineral or metallic substance, or by poisonous colors or flavors, or containing brandy, whisky, rum, wine or any alcoholic liquor in liquid form or other ingredients deleterious or detrimental to health. Nor shall any person by himself, his servant, or agent of any other person or corporation offer for sale any candy under the name of brandy, whisky, rum or wine drops.

Tuberculosis in France and England.—It is something of a surprise to read in the *Progrès Médical* of February 19, that the deaths from this disease are three times as many in Paris as in Great Britain. It quotes Tratham's statistics that in 1870, the mortality from this cause in England and Wales was 2,410 for each million inhabitants, but since consumptives have been treated in special hospitals, this number has fallen to 1,468 in 1893. In Paris there were 4,158 deaths from tuberculosis during 1894, or almost three times as many as across the Channel.

Typhoid Fever in Duluth. It is reported that the fever prevalence at Duluth has reached the amount of about 1,000 cases with thirty deaths, caused, it is believed, by the infection of the water. An inquiry disclosed the fact that the intake of the water company in the adjoining great lake was only 359 feet from the shore, was in a filthy condition, and was situated about 800 feet from the mouth of a large sewer. It appears that the superintendent himself has for a year or two procured water for his family from a spring several miles from Duluth. The city now compels the company to supply spring water to consumers without additional cost. The supply is said to be abundant and the quality of the water pure and excellent.

Commitment of New Hampshire Insane.—A supplemental act was passed in New Hampshire in 1895 which provides that when application is made to the judge of probate, or the supreme court or any justice thereof, for the committal of any person to the asylum for the insane, said court or judge may appoint two reputable physicians to examine such person, with or without notice to him or her from said court or judge. The physicians shall immediately report the result to said court or judge, who may, upon such report and such evidence as can be produced, order such person to be committed to the asylum when there is sufficient reason for making such order. And the supreme court or any justice thereof shall at any time, with or without notice, upon application and due cause shown, investigate the question whether there is sufficient reason for the detention in said asylum of any person who has been committed thereto, and shall order his or her discharge when such order ought to be made, without the formality of a writ.

To Secure Better Public Instruction. Two amendatory acts were passed by the New Hampshire legislature in 1895, one requiring the superintendent of public instruction to investigate the condition and efficiency of the system of popular education in the State, especially in relation to the amount and character of the instruction given to the study of physiology and hygiene, having special reference to the effects of alcoholic stimulants upon the human system and requiring him to recommend to school boards what he considers the best text-books upon those subjects and to suggest to them the best mode of teaching them; and the other requiring school boards to see that these studies are thoroughly taught in all mixed and in all graded schools above primary, and that well approved text-books upon these subjects are furnished to teachers and scholars.

To Prevent Blindness in Michigan.—Should one or both eyes of an infant become inflamed or swollen, or reddened, or should any pus or secretion form in the eyes or upon the edge of the lids, at any time within two weeks after birth, it shall be the duty, under penalty, according to a law passed in Michigan in 1895, of any midwife, nurse or other person having charge of such infant, to report it in writing, within six hours after discovery thereof, to the local health officer or some legally qualified practitioner of medicine in that city, town or district.

Sanitation in the Sixteenth Century.—We read in the *Annales de la Soc. Méd.-Chir. de Liège*, February, 1896, that the city of Lyons, France, possessed a Bureau of Health three hundred years ago, which was a model in many respects to the most advanced products of our own century. Its regulations provided for the declaration of contagious diseases, disinfection of residence, clothing, and bedding, and it is curious to note that the disinfecting materials employed comprised some of our best modern antiseptics, sublimate, arsenic, camphor and various essences. Our health officers will envy those of that day when they know that they were so supported by the authorities that they could enforce their regulations with penalties amounting to torture and even death in times of epidemics. "And glory to our sovereign liege, King Henry of Navarre" for his royal endorsement of such measures!

Infection of Feces in Tuberculous Cattle.—The *Bulletin Médical*, March 8, reports a series of experiments undertaken to determine whether the Koch bacilli are eliminated in the excreta of cattle and thus become a source of infection. A one-year old bull was fed, June 3, 4, 5 and 6, a meal of a certain quantity of bread and a quarter of a tuberculous lung abounding in microbes. His fecal matters were collected from June 6 to 10 and 200 grams diluted in 100 c.c. of water. Two c.c. of the liquid thus obtained, filtered, was injected into the veins of the ear of two rabbits, during the following twelve hours. Fifteen rabbits were thus inoculated. Two died of septicemia, one of intoxication, and the rest became tuberculous, with the usual bacilli and symptoms. Besides these experiments a microscopic examination was made each day, disclosing invariably the Koch bacilli. The experiments proved beyond question that the feces of cattle are just as infectious as the sputa of persons.

Diseases to be Reported in Maine.—Cases of cerebro-spinal meningitis, of measles, of so-called membranous croup, of whooping cough, and of pulmonary tuberculosis, or consumption as it is commonly termed, it was enacted in Maine in 1895, shall be reported promptly to the local board of health of the town in which cases of this disease occur; and it shall be the duty of any household who knows or has reason to believe that any person in his family or household has any of these diseases, and it shall be the duty of any physician who knows or has reason to believe that any person whom he attends or is called to visit, is affected with any of these diseases, to report the same to the local board of health. It shall be the duty of each local board of health to notify the State board of health of cases within its jurisdiction, of typhoid fever and of the diseases above named, and such notification shall be in accordance with the requirements of the blanks furnished by the State board.

Mortality in London in 1895. The deaths of persons belonging to London registered during the year 1895, were 85,138, equal to an annual rate of 19.4 per 1,000 of the population, against 20.3, 20.9 and 17.4 in the three preceding years. The rate in 1895 was 0.4 per 1,000 below the mean rate in the ten preceding years 1885-1894, although it exceeded by 2.0 per 1,000 the very low rate recorded in 1891. During the year under notice 11,166 deaths resulted from the principal zymotic diseases in London; of these, 3,574 were referred to diarrhoea, 2,628 to measles, 2,289 to diphtheria, 1,180 to whooping cough, 829 to scarlet fever, 611 to different forms of "fever" (including 5

to typhus, 596 to enteric fever, and 10 to simple and ill-defined forms of fever), and 55 to smallpox. These 11,466 deaths were equal to an annual rate of 2.6 per 1,000, against 2.8, 3.0, and 2.6 in the three preceding years. Infant mortality in London during 1895, measured by the proportion of deaths under 1 year of age to registered births, was equal to 165 per 1,000, and exceeded by 16 per 1,000 the average in the 10 preceding years.

Wisconsin State Board of Health. July, 1894, the State Board of Health of Wisconsin, adopted rules providing that no child should attend any public, private or parochial school without first presenting to the principal or teacher of the school, a certificate of a reputable physician that he had been successfully vaccinated. It adopted these rules under the provisions of law, which had been interpreted by the best legal advice that could be obtained in the State, to the effect that it was the duty of the State Board of Health to adopt such rules as in its judgment seemed necessary for the protection of the public health. In the winter of 1893, certain Christian scientists in the city of Beloit, objected to the enforcement of these rules, and obtained from Judge Bennett, a judge of the circuit court in that district, a mandamus which allowed their children to attend school, without being vaccinated, until such time as a hearing should be had before him. It is stated that this was brought about by the School Board at Beloit in attempting to enforce the rules of the State Board of Health. On June 7, 1895, the case was tried in Janesville before Judge Bennett, at which hearing the President, Dr. Marks and Dr. Wingate and another member, were present and gave evidence. The matter has been delayed ever since until a few weeks ago, when it was argued, excuses having been made by the court from time to time, of various kinds. It was then argued at great length on both sides, and the Judge took it under advisement, and has just rendered his decision, to the effect that the rules of the State Board of Health, requiring a certificate of vaccination as a condition precedent to attending the public schools, are illegal and void. He thinks that the statutes, R. S. 1407, 1408, 1409, b, c, d, do not attempt to give the State Board of Health power to make such rules, and that if the legislature attempted to do so, such legislation would be invalid as unconstitutional. He also thinks the rules are contrary to the provisions of chapter 187, relative to compulsory education. The case is to be appealed at once to the supreme court for a final decision, and it is expected to be placed on the calendar for August next.

To Ward off Malaria. Professor Maurel's article on the "Prophylaxis of Paludism," reported in this JOURNAL, March 7, p. 493, was followed at the two last meetings of the Académie de Médecine, by an address by Laborde, on the "medical" means to abort malarial troubles. The fact that an animal can be rendered immune to a disease is so thoroughly established now, that it is no longer questioned. Since the day when hereditary epilepsy was warded off by administering bromid of potassium to the morbid generator or to the mother, the proof of medical immunity was established. Laborde stated that a medicine that will cure, will also prevent a disease if taken in time, and corroborated this statement with further facts in regard to the treatment of epilepsy with bromid of potassium, as a typical mineral preventive medicine. He also described the preventive action of colchicin in cases of gout where the disease was actually held at bay for years by small preventive doses taken at the first premonitory symptoms (Dose: three or four milligram pills in twenty-four hours, of the crystallized colchicin), as a typical vegetable preventive medicine. He dwelt at length on the possibilities of this preventive medication which is not yet appreciated as it should be, and exhibited some frogs and the effect of ouarari, mentioning by the way, that he had succeeded in discovering the original plant from which it was derived and locating the essential principle of the drug, hitherto a secret process of certain tribes of the Orinoco

and Amazon valleys. To one frog he administered a fifth of a milligram of his preparation of ourari, and then gave this frog and another a tetanizing dose of strychnin. The ourarized frog showed no signs of tetanus, while the other presented a typical case of it. He insisted upon the fact that the study of bacteriologic processes is now essentially a study of the toxic products of the bacteria, and is thus analogous to the study of the effects of toxic medicines upon the body. All this was preliminary to the real subject of his address, the preventive of quinin in paludism.

He quoted numerous instances of persons exposed to the worst forms of malarial poison, who secured comparative immunity by small preventive doses of quinin. But this comparative immunity is only a proof of the grand results to be attained when it is recognized that the preventive dose must be a large one. His account of the experiences of American, English, French and Dutch ships and troops in ultra-malarial regions, was a most interesting record of what has already been accomplished in this line. He mentions Colin, Laveran, Kelsch and Kiener as the chief authorities on the subject, at present, and says that where we used to speak of the "miasm," we now say the "paludic hematozoa." We must wait another week for the continuation of this address.

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Louisiana: New Orleans, March 14 to 21, 41 cases, 36 deaths.
Ohio: Dayton, March 19 to 26, 4 cases.
Michigan: Bay City, Detroit, Inlay Township, Ionia, Marine City, Saginaw, March 14 to 21, smallpox reported.

SMALLPOX—FOREIGN.

Dublin, March 7 to 14, 2 cases.
Acapulco, March 6 to 13, 3 cases.
Bombay, February 18 to 25, 21 deaths.
Calcutta, February 8 to 15, 2 deaths.
Corunna, February 22 to March 14, 3 deaths.
Madrid, March 3 to 10, 8 deaths.
Montevideo, February 1 to 8, 7 cases.
Naples, March 2 to 9, 5 cases, 2 deaths.
Odessa, March 1 to 7, 5 cases, 3 deaths.
Paris, March 1 to 7, 2 cases.
Prague, March 1 to 7, 6 cases.
St. Petersburg, February 22 to 29, 27 cases, 7 deaths.
Swansea, March 1 to 7, 2 cases.
Tuxpam, March 1 to 7, 2 deaths.
Warsaw, February 22 to 29, 3 deaths.

CHOLERA—FOREIGN.

Bombay, February 18 to 25, 1 death.
Calcutta, February 8 to 15, 63 deaths.
St. Petersburg, February 22 to March 7, 2 deaths.
Fukuoka Ken (Japan) February 26, 1 case.

MISCELLANY.

French Congress of Medicine.—The next National Congress of Medicine in France will open at Nancy August 6. The subjects announced for discussion are: Prognosis of albuminuria; intravascular sanguine coagulations; serum treatment of diseases.

Honor for Professor Roentgen.—The Prince Regent of Bavaria has conferred upon Professor Roentgen, of Würzburg, the Knight's Cross, one of the Bavarian orders. This decoration carries with it the right to the particle "von."—*Berlin corr. British Medical Journal*, March 21, 1896.

Sale of Liquors in Indiana Drug Stores.—By the Indiana law of 1895 it is made unlawful for any spirituous, vinous or malt liquors to be sold or given away in any drug store in any quantity less than a quart at a time, except upon the written prescription of a reputable practicing physician.

Medical Supervision of Prisoners.—A law was passed in Massachusetts in 1895 that the commissioners of prisons shall make rules from time to time for the several jails and houses of cor-

rection, which shall secure such medical examination of and medical authority over prisoners confined in solitary cells for punishment as shall, as far as practicable, prevent injury to the health of such prisoners by such confinement.

Physicians in Germany.—Statistics show that our profession is increasing in Germany at the rate of 5,433 members, or 22 per cent. during the last seven years. They average 4.07 to 100 square kilometers, but some localities are specially blessed, like Tübingen, which has 3.2 per 100 inhabitants. The general average is 4.5 per 10,000 inhabitants.

Medical Register of Great Britain for 1896.—The Medical Register for 1896, which had just appeared, contains 33,601 names. The number of qualified men added during the past year was 1,416, a number slightly below the average for the last five years. There were 538 names removed during the year on account of death. Only one name was struck off the register under the penal powers possessed by the General Medical Council.

Exported American Foods of Good Quality.—A cablegram from London states that before a certain official committee on adulterations, appeared the Secretary of the Board of Agriculture of Great Britain, and that he testified that among the samples of food examined by the government fifty-one came from the United States and thirty-nine from Canada, not one of which was adulterated. Germany, he added, made the worst showing, adulteration having been found in thirty-seven out of one hundred and twenty-four samples examined.

Prescriptions of Liquor in New Hampshire. In New Hampshire a law was passed in 1895 to the effect that no physician shall give a prescription to any person for spirituous or malt liquor, wine or fermented cider, or upon which any such liquors are to be obtained, except upon reasonable evidence that it is actually needed by them as a medicine; and all prescriptions so given shall contain the full name of the party for whose use it is given, and it shall be taken up by the agent who fills it, and kept on file by him in his office and open to inspection by any person at any time. Any physician violating the foregoing provisions shall forfeit or be fined \$50.

Periostitis Accompanying Typhoid Fever.—Whether this is caused by the typhoid bacillus, the staphylococcus aureus or others, is still undecided. A couple of cases reported in a Russian journal, disclosed in one the presence of a single bacillus resembling the Klebs' bacillus, in the course of repeated examinations extending over four years; the lower third of the left arm was affected, the inflammation appearing to come and go at intervals. Another case with a purulent inflammation in the bone of the left arm, presented constantly the same microbe in the pus and urine, which resembled the anthrax bacillus, only it had rounded ends. In both cases a slight traumatism preceded the infection, and the writer concludes that this periostitis can be considered an accidental complication of typhoid.—*Annals of Liège Med.-Surg. Soc.*, February.

Infectious Diseases of Wild Animals. A disease resembling distemper is said to be killing the foxes in Gloucester County, Va. Large numbers of the foxes have been found sick or dead. A dozen foxes or more, when found by the hounds, made no run or fight at all and were killed, apparently being helpless and unable to put up a fight for life. Some years ago in West Virginia there had been deer plenty, but suddenly the deer were stricken with "black throat," or "black tongue," and died, being found all through the woods. Various other animals have been carried away in this manner, and there are steps afoot to kill off the Australian rabbits by the introduction of a bacterial disease. The nature of these epidemic diseases of wild animals should be made the subject of pathologic investigation by some of the medical fraternity on the outposts of civilization and specimens sent to the nearest laboratory.

"Medical Island" Sanitarium.—The New York *World* announces

a new substitute for the gold cure, namely, the establishment of an isolation sanitarium in the Pacific ocean. "Medical Island" is the name which has been given by a syndicate of physicians from New York, Paris, London and Berlin to a tropical island of volcanic origin, eleven days' sail from San Francisco. Here is to be elaborated a model sanitarium for the cure of the drink and opium habits. There will be no hotels or boarding houses, but in their stead there will be three handsome club houses without bars. Patients must consent to remain away from the continent for one year, and pay all expenses for that time in advance. The island is under the jurisdiction of Great Britain, from whom the syndicate will secure its needed concession. The scheme is a feasible one and will be adopted by some one, if not by this alleged and unnamed syndicate.

The Effect on the Taste-Buds of Severing the Glosso-Pharyngeal Nerve.—Baginsky has recently denied the assertions of Vintschgau and Hönigschmied that the cutting of this nerve causes the necrosis of the taste-buds. In order to settle the question Sandmeyer severed this nerve on one or both sides, in seventeen young and full-grown rabbits, on a level with the large cornu of the hyoid bone. The rabbits were killed four to forty-one days after the operation, and degenerative conditions were found in every case, from the slight indications of it in those killed in four days, to the entire disappearance of the taste-buds, after twenty-seven days.—*Centralblatt f. Phys.*, February 22.

The Prizes to be Awarded by the Paris Academy of Medicine.—Thirty-one prizes are offered annually by the Académie de Médecine for the best article on certain subjects. This year they are as follows: Prevention, treatment and cure of tuberculosis, insanity, cancer, etc., morphinism, epilepsy, melancholia, diseases of the ear, dysentery, diphtheria and malaria. Others are offered for the finest contribution to hygiene, medical science, medical history, therapeutics, medical statistics, surgery, internal pathology, heredity and the application of physics or chemistry to medicine, and others for any work on any medical subject that advances the progress of humanity, therapeutic surgery, and practical medical therapeutics. Others are for the best work on the study of the lymphatic system, and the relations between the thermogenesis and the respiratory processes. One prize is to endow a special scientific mission. Many articles have been received to compete for the prizes from many sources, but we do not notice any American names among them.

Febrile Albumosuria. Krehl and Matthes conclude from various experiments that there is a certain albumose in febrile urine, or deuto-albumose, caused by bacteria, which disappears with the febrile conditions, but which will produce fever if introduced into another organism. They found the presence of albumose in the urine almost always coincident with febrile conditions, but in cases of ulcer and carcinoma ventriculi, there was albumose but no fever, and in a few cases of malaria and phthisis the fever was unaccompanied by albumose. The albumosuria disappeared simultaneously with the fever in the cases of scarlatina, diphtheria, influenza and parotitis infectiosa observed. Various tests showed that it was a deuto-albumose, and in cases of acute peritonitis, croupous pneumonia, erysipelas and scarlatina it was accompanied by an albuminoid precipitated by free ammonia, forming with baryta an almost insoluble combination, perhaps analogous with "Kossel's hyston."—*Centralblatt f. Phys.*, February 22.

Study of the Distribution of the White Blood Corpuscles. Semakine announces that contrary to the statements of Rieder and Schultz, the white blood corpuscles are distributed evenly throughout the blood vessels. Analysis of the peripheral vessels is therefore a correct means of determining the number of leucocytes in the central arteries and veins. Hypo- and hyper-

leucocytosis are therefore not only the expression of altered conditions, but also of an actual decrease or increase in the number of leucocytes. He warns investigators against the use of rabbits in these experiments, as they react to the slightest disturbance, such as fastening them to the board, or a slap on the head, with an alteration in the number of their leucocytes. The number of leucocytes in rabbits is also very much influenced by the opening of the abdominal cavity, exposing the abdominal organs to the air. It affects them similarly to a cooling off of the animal in general, which always diminishes the number of leucocytes. To this fact is due the decreased number of leucocytes found in the abdomen by Rieder and Schultz. If the abdomen is protected against cooling by the air, there is no difference between the number of them found here or elsewhere. Another cause of their error is that they operated on dying or dead rabbits, and death produces many changes in the distribution of the leucocytes.—*Centralblatt f. Phys.*, February 22.

Burdette's Rhymes on the Adulteration of Food.—All lecturers on physiology will be glad to have the following lines printed where they will be within their reach. The poet began his weird repast with some kind of bread that is raised with a plaster-of-paris baking powder, and so on:

A VICTIM OF DELUSION.

Placid I am, content, serene,
I take my slab of gypsum bread,
And chunks of oleomargarine
Upon its tasteless sides I spread.

The egg I eat was never laid
By any cackling, feathered hen;
But from the Lord knows what 'tis made
In Newark by unfeathered men.

I wash my simple breakfast down
With fragrant chicory so cheap;
Or with the best black tea in town—
Dried willow leaves—I calmly sleep.

But if from man's vile arts I flee
And drink pure water from the pump,
I gulp down infusoriae,
And hideous rotatoriae,
And wriggling polygastricae,
And slimy diatomaceae,
And hard-shelled orphryocercinae,
And double-barreled kolpodæ,
Non-loricated ambroëile,
And various animalcule,
Of middle, high and low degree;
For nature just beats all creation
In multiplied adulteration.

An Unusual Case of Bone Grafting. Before the Medical Society of London, Mr. Waterhouse reported upon a case where it "was necessary to scoop out the body of the os calcis for the removal of tuberculous disease: a foot was left, in which this important bone was represented only by a yawning cavity, bounded by a thin shell of compact bone. The outer wall of the cavity was wanting and the floor was badly damaged. This resourceful surgeon," says the *Medical Press and Circular*, February 12, "thereupon requisitioned the collar bone of a lamb (part of a shoulder of lamb which had been served for the dinner of the resident medical officers of the hospital). He decalcified the bone by steeping it in hydrochloric acid, freed it from fat by washing it in ether, and then sterilized it by immersion in a solution of carbolic acid of suitable strength. The bone having been converted into chips was made into a paste with iodoform and packed carefully and tightly into the gaping cavity, over which the skin was securely sutured and the foot was then put up in an antiseptic dressing. It was not dressed again for a fortnight or so, and by that time healing was complete and has remained so ever since. We gather that this is the seventh or eighth case in which Mr. Waterhouse has employed this procedure with the same measure of success,

and on this ground the method commends itself for general adoption in this class of cases. We have seen a finger grafted on or into a nose, and a chicken bone used to patch up this or that small bone, but the utilization of a lamb's collar bone to build up an absent heel is as interesting, and even as extraordinary, as either."

A Charge of Plagiarism Turned to Good Account.—The *Medical News* adverts to an anonymous foreign charge of plagiarism against a certain American system of surgery. The sting of the condemnation is slyly extracted and converted into a balm of commendation. And this is the way it is done: "Scant attention need be paid to an anonymous paragraph that has appeared in an English periodical, charging plagiarism against the new System of Surgery by American authors, the concluding volume of which will shortly appear. The charge is devoid of details and the name of the accuser is withheld, so that more than a general and absolute denial of the truth of the statement is alone possible. American surgeons have neither need nor desire to borrow ideas or language from their English *confrères*. The derivation of illustrations from various sources is customary on both sides of the Atlantic, and is a practice common to nearly all medical works, without regard to country. The essence of the charge seems to lurk in the fear that the American System of Surgery would prove too successful a rival to native works, and hence the attempt on the part of English publishers to protect their market against competition. What higher compliment could be paid to the excellence of this latest production of American surgeons—the confession of fear to submit to rivalry?" But we understand that the work has been excluded from sale in Great Britain.

Asbestos in Boots and Shoes.—The *Medical Press*, February 26, states that a company has been formed to make boot soles out of asbestos, or rather to make asbestos a part of the sole. This material has the properties essential to a hygienic and comfortable footgear, being light and a non-conductor, and with "the mineral replacing leather or felt, as an inner sole, the boot may be worn on the hot flags of a city street on a summer day, or on slush or snow in winter, without the wearer being made uncomfortable by either. During the eighteenth century asbestos was much more used for wearing apparel than at present, even two centuries earlier the spinning of asbestos was a recognized industry in Venice. Signor Castaquatta carried the art to such perfection that his woven asbestos was soft and tractable, resembling dressed lambskin. He could thicken or thin the product at pleasure, and thus either make it a very white skin or a very white paper. Signor Ciampini describes the method of weaving asbestos thus: The stone is laid to soak in warm water, then opened and divided by the hands, that the earthy matter may be washed out. The washing being several times repeated, the flax-like filaments are collected and dried: and they are most conveniently spun with an addition of flax. Two or three filaments of the asbestos are easily twisted along with the flaxen thread, if the operator's fingers are kept well oiled. The cloth also when woven is best preserved by oil from breaking or wasting. On exposure to the fire the flax and oil burn out, and the cloth remains pure and white, a light, durable, non-conducting fabric."

Purulent Pleurisy with Dead Streptococci.—Sterile pus has been found in various abscesses, hepatic and cutaneous, in pyosalpinx, etc., that did not disclose any microbes in the most rigid tests, or showed traces of them with the microscope, although cultures and inoculations remained negative. These differences are due merely to the stage at which the experiments are made. The *Archives Clin. de Bordeaux* for February contains an account of a similar occurrence in a case of purulent pleurisy accompanying pulmonary tuberculosis. An operation for empyema resulted in the withdrawal of 1,800 grams of fetid pus, followed by marked improvement in the condition of the

patient. Numerous tests and cultures of all kinds with the inoculation of a couple of rabbits all remained negative, as far as the development of the streptococci, which were present in large numbers, was concerned. They must have been dead, killed by the toxins of which they were the original cause. This refutes the theory of some that the disappearance of the microbes in abscesses of the liver is due to a special secretion of that organ, as we see that it occurs in other parts of the body. In the above case the tubercle bacilli were not at all virulent, and could not have been the cause of the suppuration. One rabbit inoculated showed no trace of the Koch bacilli, and in the other, the only result was a white swelling (tuberculous) in two joints. No other microbes were found in them after they were killed.

Meta-pneumonic Purulent Pleurisy.—By this is meant that form of pleurisy which accompanies or follows pneumonia and persists as a separate disease. It is often mistaken for conditions left by the pneumonia, and treated incorrectly, so that it is important to study carefully its indications. In pneumonia proper the pneumococci die in the products of their own secretions, but sometimes they survive in the pleura, and cause the phenomena we call meta-pneumonic pleurisy. The patient is recovering from the pneumonia: all is going well, and medical attendance often discontinued. But in a few days the improvement ceases: the patient feels worse again, with slight fever in the latter part of the day. All causes are ascribed except the right one. The diet is changed, bowels loosened, chest blistered, perhaps, weakening the patient and hindering correct diagnosis. If the signs of pleurisy are not very marked, and they seldom are, incipient tuberculosis is assumed, and supposed to be the cause of the emaciation, cough, fever and night sweats. This goes on until some other physician sees the case and examines it without prejudice, and discovers the indications of a purulent effusion, or until the effusion is absorbed or finds its way to the surface, to the surprise of all. An exploratory puncture should always be made in such a case, and sometimes it will have to be repeated two or more times before certainty is attained. The above is from an article by Professor Desplats in the *Jour. des Sci. Méd. de Lille*, February 15, including observations of several cases in his own practice. He adds that of the five ways in which this disease terminates: Absorption, vomiting, empyema, formation of a cyst and extension of the infection, almost all require surgical assistance, and vomiting of the pus should be forestalled, as it is apt to persist a long while and end in death.

Advice to Medical Writers. The editor of the New York *Poly-clinic* offers a semi-decalogue to those of its friends who send to it carelessly written articles. As those friends will not have time to look at the hints, we will print them for our own use and for that of our friends—the readers of papers. The *Poly-clinic's* five cardinal points for authors are: 1. "In your writing be, above all things, *purposeful*; afterward, concise, relevant, definite. 2. The subject selected should contain but one definite line of thought: should not be trite: should be one in which you are personally interested; if argumentative, one in which you have convictions. It should be suited to your abilities and to your opportunities for forming a correct judgment and should be no broader than the essay itself. 3. Make an outline of your subject: it will enable you to read up accurately and profitably; it will afford mental discipline. 4. Be careful to pay attention to the elegance of your language; to such little things as correct paragraphing and punctuation. 5. Above all, remember that the analytical writer is the strong writer." In the body of the article the editor presents five considerations, minor, to him, apparently: but some of them of prime importance to audiences that need to sit and not get weary over *details and details and details*. These five other points, in our own language, may be condensed as follows: 1. Your audi-

ence should not be expected to do all the analyzing of your cases. 2. You need not go back to Galen and Avicenna and Sigault in every essay. 3. Where a similar line of therapeutics has been employed for a series of cases, the intelligence of your audience may be assumed to be sufficient to supply some of the gaps, as you pass with lighter hand over the later cases. 4. Make your preface short. "I will grant you," says the editor, "that there is a sort of hereditary precedent for scientific men, as a rule, to wander afield in their discussions, and to indulge in more or less verbosity of speech; but the writer, who, after an intelligent discussion of the subject, brings all the evidence to bear upon a definite conclusion, is bound to be the most respected while he who deals largely in words, sometimes utterly lacking in definiteness, will become more and more a bore, as medicine continues to make rapid progress toward becoming a science rather than an art." 5. Take down your long unused works on rhetoric and logic, if you feel that you have fallen into careless ways of composition or of argument. The above admonitions may be summed up in a brief commandment: Put yourself in the place of your audience as you pass along from point to point in your dissertation; be at once objective and subjective. Moreover, some of our ever-welcome medical writers find it not beneath their position to enliven their production with a dash of color of humor or personal narrative. But this is not always possible, the subject not warranting it, and with some it is impossible, the mental build of the author forbidding it.

Practical Notes.

The Treatment of Hydrophobia at the Institut Pasteur during 1895.—Pottevin (*Annales de l'Institut Pasteur*, February, 1896), reports the following concerning the inoculation against hydrophobia at the Institut Pasteur during 1895: Number treated 1,520, dead 2, mortality 0.13. This is the smallest death rate since the beginning of Pasteur's treatment. Of the persons who were inoculated 257 were foreigners and 1,263 French.

Method of Introducing a Sound in Cases of Apparently Impassable Stricture of the Urethra.—Gigli, of Florence, accomplishes this with an irrigation of the urethra with a hot solution of salicylic acid, introduced through a rubber tube from a reservoir above. The edges of the opening are to be compressed with the fingers so that the liquid will not run out. It dilates the urethra so that in a few minutes the catheter can be introduced under the glass canula in which the tube terminates. —*Semaine Médicale*, March 11.

Treatment of Purulent Gastritis by Bismuth. The fasting stomach is first washed out in the morning with a soda bicarbonate solution, and then a solution of 10 to 15 grams of subnitrate of bismuth in 500 grams of filtered water is introduced after it has been thoroughly shaken. The bismuth forms a precipitate on the walls of the stomach in about ten minutes, when the water is to be withdrawn, a delicate operation, as the bismuth is not to be disturbed. —*Revue Internat. de Méd. et de Chir.*, March 10.

Local Temperature in Disorders of the Urethra and Prostate Gland. Barrucco announces in the *Gazz. degli Osped. e delle Clin.* of March 7, that he has found the local temperature of the greatest service in diagnosing diseased conditions of these organs. His sound is fitted with a thermometer inside, and promptly discloses any local pyrexia. The rectal sound also is provided with a thermometer. This article is from a large work on this subject which he is soon to publish, "Modern Instruments for the Cure of Disorders of the Prostate Gland and Bladder."

Otitis in Typhoid Fever. The hearing is often affected in this disease. Botkin states as the results of observation in twenty six cases, that he found in all but five an acute and bilateral inflammation of the outer ear. The inflammations that invade the ears in the course of scarlet fever and measles, are sufficiently familiar; but there are comparatively few

observations recorded of these affections in typhoid, croupous pneumonia, etc. He concludes by recommending that the ears be examined as often and with as much care as the mouth and throat.—*Annales de la Soc. Méd.-Chir. de Liège*, from the *Medicinskoe Obosreujie*.

Rapid Method of Estimating the Quantity of Sugar in Urine.—It is often important for the physician to know at once the amount of sugar in the urine in a case of diabetes, and yet the ordinary methods are too complicated to use at the bedside. To meet this want a writer in the *Bull. Méd. Par.*, November, 1895, announces the following formula as a rapid and accurate method: Count out into a test-tube 20 drops of Fehling's solution, heat this to the boiling, add the urine until the color test is sufficient, and divide the invariable number 100 by the number of drops taken; the result will be the proportion of sugar to the liter in grams and centigrams.—*Nouveaux Remèdes*, February 24.

A New Anastomotic Button.—Boari, of Ferrare, has applied the idea of the Murphy button to another organ and uses a similar contrivance in establishing an ureter-intestinal graft. He has never applied it yet to a human being, but it has worked finely in his experiments on dogs. Whether this operation is to be recommended at all, is another question. Some think it leads to a secondary nephritis caused by ascending infection, and have consequently abandoned it. It seems preferable to imitate, as much as possible, the natural processes, and therefore the operation of replanting the ureter in the bladder, as Basy performs it, is the one preferred by most.—*Gaz. Méd. de Liège*, March 12.

Anthelmintic Remedies.—The following recipes are republished from the last numbers of the *Allgem. med. Cent. Ztg.* in the *Annales de la Soc. Méd.-Chir. de Liège*, February, 1896.

R Chloroform. 4 grams.
Croton oil. 1 gt.
Glycerin. 30 grams.

Misce. Sig. Take at one time.

R Pure iodine. 0.75
Potassium iodid. 2.25
Distilled water 30.00

Misce. Sig. Ten drops three times a day.

R Croton chloral. 4.05
Gum tragacanth. 0.01
Gum arabic. 0.25
Simple syrup. xxv gtt.

Misce. Sig. Fiant xxiv Pilule. Take four at night and four next morning, fasting. After a light breakfast take 100 grams of an infusion of senna to which has been added xv drops of alcohol containing 10 per cent. of chloroform.

Leucoplasia Buccalis.—Jullien presented a typical case of this disease at the February meeting of the Society of Dermatology at Paris, which had resisted every kind of treatment. The dorsum of his tongue showed the characteristic silvery patch, four centimeters long and one and a half wide. It is not painful and does not trouble him except slightly in speaking. He is a dyspeptic and has had syphilis, and was a great smoker at one time. The urine contained traces of albumin and sugar, with hemaphcin, urohematin, uroerythrin, indican and bile. All the mineral constituents and the urea are present in enormous quantities. There is also hepatic insufficiency and excessive intestinal fermentation. Bacteriology has nothing to say in these cases. There are traces of hyperkeratosis, and Stansiale has shown that in leucoplasia there are elements similar to those found in degeneration of the epithelium. Other members present advised immediate recourse to thermo- or galvano-cauterization. —*Revue Int. de Méd. et de Chir.*, March 10.

Movable Kidney. Guyon describes several cases of wandering kidney that have come under his observation, in the *Indépendance Médicale*, Dec. 3, 1895. He states that most frequently the kidney does not cause pain or very little. And when it

does, the pain is not in proportion to the amount of displacement. There are two methods of examining for a movable kidney, Guyon's bimanual exploration assisted by the special manipulation producing the sensation of "ballotement" as practiced in pregnancy, and Glenard's. To determine the lateral and transverse displacement the subject should be examined in the decubitus lateral on the opposite side. Beside the disorders due to displacement, it must not be forgotten that the ureter is liable to be obstructed, which may produce the symptoms of an intermittent hydronephrosis.

Comparative Merits of Potassium Iodid and Sodium Iodid.—The relative merits of these drugs is still an open question with many. Laborde and Sée deny any merit to sodium iodid, while others assert that the dangers of potassium iodid are such that the former should be given the preference in every case. Briquet has been making a careful comparative therapeutic study of them lately, and reports that the effect of potassium iodid is more marked in most cases than the other, equal to it in heart troubles, very much superior to it in disorders of the respiratory organs and in cases of dyspnea, as well as in certain rheumatic troubles. He concludes that the use of potassium iodid is to be preferred and that the toxic effects attributed to it have been much exaggerated.

Treatment of Prostatitis with Hot Water and Potassium Permanganate.—Abeille, of Nantes, has been very successful with an original treatment of gonorrheal prostatitis, which he describes as follows in the *Revue clin. d'And. et de Gyn.* After securing anesthesia of the urethra with cocain, he introduces a Nélaton sound No. 12, and connects it with a reservoir containing potassium permanganate at 1 per 4000 or 1 per 2000 according to the ability of the urethra to support it, at a temperature of 35 to 38 degrees C. The liquid passes through the sound up to the sphincter and flows out between it and the walls of the canal. When the penile portion is thus well irrigated the sound is inserted through the sphincter, without interrupting the flow of the liquid, and the bladder receives the same cleansing. If there is a strong desire to urinate the urine can pass out through the sound. With this treatment Abeille has aborted many a case of prostatitis which would have suppurated if left to itself. —*Revue Internat. de Méd. et de Chir.*, March 10.

Novel Variety of Incontinence of Urine.—Albarran describes an unusual form of incontinence of urine, in the *Annales des Maladies des Org. Gen. ur.*, December, 1895. The subject was a degenerate, nervous girl who for nine years had been unable to control the flow of urine except when lying down. Investigation disclosed that the bladder and uterus were united with an abnormal adherence which caused the vesico-urethral sphincter to gape when standing or sitting, but in a reclining position, the weight of the uterus caused it to fall back, thus closing the sphincter. The organs were slightly malformed, but nothing serious. She was entirely cured of the incontinence by an operation in which an incision was made into the anterior wall of the vagina, extending from the neck of the uterus to the neighborhood of the urethra; the uterus was detached from the bladder with the fingers and scissors, and the space thus left stuffed with iodoform gauze. Fifteen days later the neck was treated with faradization three times. Fifteen months have passed since the operation with no symptoms of a relapse.

Formol in Ophthalmology.—Strzeminski has been making a study of this drug in the treatment of diseases of the conjunctiva, the cornea and blepharitis. He announces that it is ineffective in the latter, and only moderately successful in suppurative and gonorrheal conjunctivitis, in connection with nitrate of silver, which is the best medicine for them yet announced. It has no effect on trachoma in acute cases, but assists recovery in chronic cases, employed at intervals. But an ulcer of the cornea formol cures in seven to ten days. The hypopyon in one case disappeared in four days. In torpid cases of ulcerations,

abscesses, etc., formol is not superior to the usual drugs employed. The explanation of these results is probably that formol is destructive to the staphylococcus, but is harmless as far as the streptococcus and the gonococcus are concerned, which confirms the observations of others who have tried it in the treatment of gonorrhea in the female. In conclusion the author warns against the use of antiseptics in cleansing the conjunctiva; sterilized water alone should be used. —*Nouveau Remède*, February 24.

To Remove Hardened Wax from the Auditory Canal.—Laurens writes to the *Indépendance Méd.* to warn against the use of instruments of any kind, as it is liable to be followed by the most serious consequences. He recommends the syringe alone, well sterilized and filled with boiled tepid water. It should be introduced along the upper wall of the canal so that the water will sweep the plug out with it, and five times full is enough for one day. The greatest care should be taken to work gently, and stop at the first trace of pain or vertigo. The plug can be softened with the solution of carbonate of soda, 1 gram in 20 grams of glycerin and water. Ten drops of this are to be warmed and poured into the ear three times a day; the head should be held so as to keep it in the ear for a while and then a tampon can be inserted. The injection should be repeated in forty-eight hours. In case the plug of wax adheres to the meatus it should be seized with the pincers and held, while the injection is repeated until the plug comes out, when the canal should be wiped carefully with the finger wrapped in a sterilized rag, and a cotton plug inserted for a few days. —*Gaz. Méd. de Liège*, March 12.

Danger in Purgatives in Certain Cases.—A case of acute diffuse peritonitis with alarming symptoms was treated by laparotomy, when the small intestine was found twisted around the vermiform appendix in which there was a small perforation. The occlusion was complete, but fecal fluids escaping through the hole in the appendix, had produced a serious condition. Winiwarter describes his treatment of the case, with the removal of the appendix and an incision in the intestine to remove the accumulated gases. The abdomen was sutured without drainage, and the patient made a complete recovery. He remarks that in such cases there is scarcely any means of determining the presence of a perforation, yet if a purgative were administered, instead of the opiates he ordered, the increased peristaltic movement of the bowels would have forced fecal matter through the hole and a putrid, fatal infection would have been the result in all probability. —*Annales de la Soc. Méd.-Chir.*, de Liège.

Management of Placenta Previa.—This is one of the most serious incidents that can occur in parturition, and the physician will do well to be familiar with every method of handling it. Nijöhoff describes in the *Nederl. Tijdsch. v. Verlosk. en Gyn.*, 1895, No. 11, a case of this kind, showing how he treats it. He endeavored to turn; was unable to perforate the amniotic membrane with his finger, but by pulling it here and there, he succeeded in detaching it from the inner surface of the placenta. This caused that part of the amnion opposite the cervical mouth to protrude into the vagina, with such a pressure from the fluid, that it held the hemorrhage in check, especially when a tampon was inserted into the vagina, until the child was spontaneously delivered, only slightly asphyxiated. This method is no worse for the mother, while it gives the child a better chance than others, like Braxton-Hicks' for instance. The mortality from placenta previa, direct or secondary, has been much reduced in late years, but it is still higher than it should be.

Surgical Treatment of a Paralytic Twisted Foot.—Where the deformity consists in a functional defect in the peroneal muscles, Winkelmann suggests the grafting of the tendon of the muscles in the outer side of the leg, near the gastrocne-

mius. An incision along the outer edge of the gastrocnemius, extending to the upper part of the malleolus, exposes these muscles. Then with a transverse incision from the outer half of the gastrocnemius to the point where it joins the soleus, separate this half with an ascending incision, loosening the flap, and cut the tendon of the peroneus longus at the same level. If the parts have become dry, moisten the tendon of the peroneus brevis, and suture it to the central part of the peroneus longus. Beside this method Winkelmann suggests also the following: Complete transverse section of the gastrocnemius and division of the muscle into two halves, an inner and an outer: the first to the tendon of the peroneus longus, the second to the tendon of the extensor muscle of the toes. By this means the antagonists to the soleus, help dorsal flexion and also help to bring the inner side of the foot down to its normal position.—*Archivio di Ortopedia*, No. 1, 1896.

Effect of Chlorhydrate of Phenocol on Whooping Cough. Vargas reports in the *Ther. Woch.*, 1896, No. 1, that after trying every remedy recommended for this disease, he found chlorhydrate of phenocol the one specific, in doses according to the age of the child and the severity of the attack. He disguised the unpleasant taste with syrup and in forty-two cases treated, he did not encounter a single evil result, no diarrhea, vomiting or erythema. It was rapidly eliminated in the urine; Hertel's test showed that it passed out of the body in twenty minutes after it was administered, continuing to be eliminated through the following fifteen to twenty hours. It subdued the paroxysms of coughing, reducing the number and intensity in from six to twelve hours. It should have been kept up for two or three weeks. He queries what can be the cause of this relief, and assumes that it has nothing to do with bacteria, as it is administered by the mouth, and thus does not come in contact with the membranous surfaces of the nose, throat or larynx. He ascribes it to the soothing effect of the drug on the trigeminal and laryngeal nerves, as evidenced by the first effect noticed, which is the diminishing convulsiveness of the spasms of coughing. Reviewed in *Nouveau Remèdes*, February 24.

Chinosol, the New Antiseptic.—The advantages of this new antiseptic over sublimate and phenic acid, are that it is so slightly toxic that the solution used could be drunk with impunity. Three grams of it can be injected subcutaneously into a rabbit without danger, and yet it arrests the development of bacteria. A solution of 1 to 10,000 will arrest the development of the staphylococcus pyogenes aureus. While it is as powerful an antiseptic as sublimate, it does not injure the hands even in a 1 to 500 solution. It is sold in tablets readily soluble in water, so that the quantity can be accurately graduated. It is a neutral compound of oxy-chinolin, with no pronounced nor disagreeable odor. Kossmann recommends it in high terms, and mentions its only disadvantage, that it leaves a yellow stain on the hands and linen, which is easily washed off in clear water. He has used it extensively in his practice, with never a trace of subsequent intoxication or eczema. It has no caustic effect when used as a powder on wounds and ulcerations with profuse secretions, but it is in confinement cases that it is especially serviceable, for the general use of the nurse, as sublimate is too dangerous to be thus used indiscriminately, and phenic acid is too corroding in a 5 per cent. solution to wash the hands freely, while a weaker solution has no aseptic effect.

Nouveau Remèdes, February 24.

Pott's Fracture Treated by Early Strapping. The London letter of the *American Practitioner* recounts the case of a self-treated Pott's fracture in the person of a prominent London surgeon. Mr. Noble Smith, F.R.C.S., recently fell and received a Pott's fracture, the fragments being separated by more than an inch. He determined to try early strapping, early movement, and massage; this treatment was attended with the hap-

piest result. Within half an hour of the accident the foot and ankle were strapped before any appreciable swelling had taken place, and the ordinary back splint, supporting the foot, leg and thigh, with side pieces, was applied. The strapping was lightly applied, with no attempt to apply pressure, and was daily adjusted according to the tension. The strapping was discontinued on the seventh day. On the fourteenth day plaster of paris splints were put on. From the first, very gentle movement of the ankle joint was submitted to. Avoiding disturbance of the fractured bones, massage was begun slightly during the first week and increased by degrees. On the twenty-first day Mr. Smith could bear the weight of the body on the injured leg. On the twenty-third day he walked with caution. On the thirty-second day he could flex and extend the foot nearly as well as the sound one, and on the thirty-fourth day he gave up crutches, using instead two sticks. On the forty-second day he walked two miles with sticks.

Treatment of Purulent Ophthalmia By Copious Irrigation.—Dr. Kalt reports that the number of cases of ophthalmia treated by him and his hospital colleagues by copious irrigations of potash as he has advised, is now 200, 31 adults and 169 newborn. He prefers permanganate of potash to permanganate of lime, as it is less irritating. For both, the proportion should be 1 gram to 3 liters of water at 25 degrees C. Permanganate of lime or potash 20 grams, distilled water 300 grams, a teaspoonful to a liter of water. Each eye should receive 1.5 liter of this fluid at a time. The first two days four irrigations should be made, three only with permanganate of potash; then three for two or three days; finally, two until the end. They should not be arrested until all secretion has disappeared for two days. If the affection lasts more than fifteen or eighteen days, recourse should be had to permanganate of potassium. The same journal from which the above is taken, the *Annales d'Oculistique*, contains a cautionary article by Dr. Van den Burgh, entitled "The Danger of Sublimate Lotions and Applications of Nitrate of Silver as a Prophylactic Method with Premature Children, as a Cause of Fibrinous Conjunctivitis." In it, the writer reports a case in which 1 per 1,000 lotions of sublimate during delivery, and afterward the application of Credé's method, that is, the introduction of a 2 per cent. solution of nitrate of silver into the conjunctival cul-de-sac, were followed by the development of severe fibrinous conjunctivitis which nearly caused the loss of both corneae. He concludes that in the prophylaxis of ophthalmia of the newborn caustic substances, such as nitrate of silver, or those which are not well tolerated by the conjunctivae of children, such as lotions of sublimate, should be proscribed. This rule should be absolute in children who are weak and sickly and those who are qualified as premature. As a prophylactic agent he prefers iodoform.

Washington Notes.

HEALTH OFFICE WEEKLY REPORT. The report of the Health Officer for the week ending March 21 is as follows: Number of deaths (still-births not included), 130; death rate per 1,000 per annum, 24.5; death rate per 1,000 per annum for the corresponding week last year, 24.2. The rise in the death rate week before last was followed by an additional rise last week. The deaths reported to the health department numbered 130 as against 121 in the preceding week. Correspondingly the death rate advanced to 24.5 from 22.8 per thousand inhabitants. The principal diseases causing this mortality were those of the lungs, brain, heart and kidneys.

FOR THE CHILDREN'S HOSPITAL.—A matinee performance will be given at the National Theater during the present week for the benefit of the Children's Hospital.

TO PURCHASE A QUARANTINE STATION.—Speaker Reed's bill H. B. 7471, providing for the purchase of the buildings and contents comprising the quarantine establishment of the city

of Portland, Me., located on House Island, in Portland Harbor, has been referred to the Committee on Military Affairs.

THE SUNDRY CIVIL APPROPRIATION BILL.—The Sundry Civil Appropriation Bill was reported to the House on March 2. The committee omitted from the bill the provision of \$19,000 in the last bill for Providence Hospital, \$19,000 for Garfield Hospital and \$34,500 for Howard University. As a substitute for the above omitted appropriation the following is introduced: "For the support and medical treatment of medical and surgical patients who are destitute in the District of Columbia, under contract or contracts to be made with responsible and competent persons or institutions by the Surgeon General of the Army, \$38,000, or so much thereof as may be necessary. Provided that no payment shall be made under any such contract except for service actually rendered, for which specific compensation shall be provided under such contract."

MEDICAL SOCIETY.—At the meeting of the society held on the 25th inst. Dr. Clayton reported a case of uremia with high temperature complicated by opium poisoning. Dr. Burnett read a paper on formalin in ophthalmic practice, and Dr. J. T. Johnson reported a case of hysterectomy.

Cincinnati Notes.

THE ACADEMY OF MEDICINE has decided to assume the management of the present directory for nurses. An office will be established in the central part of the city and arrangements will be perfected whereby nurses can be had at a moment's notice either day or night. A committee consisting of Dr. N. P. Dundridge, Dr. R. W. Stewart, Dr. G. M. Allen, and Dr. Wolfstein was appointed to perfect the arrangements.

DR. CHAS. A. L. REED read a paper before the Academy of Medicine entitled "Appendicitis." He dwelt more particularly upon the histology, etiology and varieties.

THE ACADEMY OF MEDICINE LIBRARY is to be located in a special division of the Cincinnati Hospital Library.

DR. DAVID DE BECK recently presented to the Academy a case of sub-conjunctival cyst. The patient was a young colored woman in good health. There were three cysts in the right eye averaging about ten millimeters long and four millimeters in depth. One of the cysts was removed without rupture.

SURGEON FRANK W. HENDLEY, of the First Regiment of O. N. G., of this city, has recently completed a medical and surgical chest designed for both field and camp service. It is the same size as the old style army pannier and contains not only the necessary medicines but the instruments as well.

THE DREAD of an epidemic of smallpox at Dayton seems to be increasing. The workhouse cases are now four female inmates. One case has been reported in close proximity to the most aristocratic portion of the city.

AN EFFORT is being made to have the legislature pass a law increasing the strength of the Hospital Corps of the National Guard to twenty-four men and four hospital stewards to each regiment, instead of one steward and eighteen men as at present.

DR. JAMES T. WHITTAKER delivered an address, March 25, before the Unity Club on the subject of "Medicine and Surgery of the Queen City." [To be printed in this JOURNAL next week.]

THE ANNUAL APPROPRIATIONS from the legislature are presented as follows: Board of Health \$6,250; Dairy and Food Commission \$14,600; Athens' State Hospital \$102,938; Cleveland State Hospital \$99,945; Columbus State Hospital \$165,501; Dayton State Hospital \$100,125; Toledo State Hospital \$144,260; Longview Asylum Hospital \$116,000; Massillon State Hospital \$100,000; Education of the Deaf \$75,123; Institution for Feeble Minded Youth \$120,411; Ohio Hospital for Epileptics \$181,925; Institution for the Blind \$41,561.

THE FOLLOWING are the appointments, announced by Governor Bushnell, to constitute the Board of Medical Examiners in accordance with the provisions of the Kimmel Bill, which

was recently passed in Ohio, and which provides for the examining and licensing of all persons who desire to practice medicine in the State of Ohio: Dr. N. R. Coleman (R.), Columbus, 7 years; Dr. H. E. Beeby (H.), Sydney, 6 years; Dr. Chas. A. L. Reed, Cincinnati, 5 years; Dr. David Williams (E.), Columbus, 4 years; Dr. S. B. McGavran (R.), Cadiz, 3 years; Dr. Cady Markley (Ph.-med.), Toledo, 2 years; Dr. J. K. Scudder (E.), Cincinnati, 1 year.

Louisville Notes.

DR. C. T. POPE, physician to the Eruptive Hospital, has resigned his position owing to an order sent him by the Board of Public Safety, requiring him to spend all of his time at the hospital so long as there is any likelihood of smallpox developing in the exposed neighborhood.

LEGISLATIVE ACTS.—The following bills were favorably reported and passed by the Senate but owing to the political fight for United States Senator failed to pass the House: A bill to authorize coroners in counties with a certain population to employ coroners; a bill to establish the office of physician to the jail in counties containing a population of 150,000 or more; a bill to make the pharmacy law apply to all cities and towns in the State.

HOUSE OF REFORM.—The full text of the bill creating a House of Reform, for boys and girls, has just been published. This bill passed both houses and has been approved by Governor Bradley. There are to be two separate institutions, one for boys and a similar one for girls, the sum of \$100,000 being appropriated for their establishment. The government of these institutions is to be vested in a board of trustees consisting of six persons, three women and three men, appointed by the Governor and approved by the Senate. Vacancies in the board, other than by limitation, are filled by nomination by the board, with the approval of the Governor. The trustees may be reappointed. Suitable sites are to be purchased, to consist of not less than one hundred acres, near some city or town, but not less than three miles of the corporate limits thereof. In the arrangement of the buildings, etc., all cells and bars are to be omitted so far as possible, and what is known as the "Cottage Family Plan," adopted. Each family house is to be occupied by from eighteen to twenty-five boys or girls, with matron, teacher and housekeeper, making it as far as practicable a well-ordered home. The objects of the institutions are described as not merely a place of detention, but of reformation of those who by reason of vicious conduct or moral depravity have rendered themselves a burden to their relations and society. Kindness, firmness and competency are to be required of those in charge. The board can bind those who are suitable for apprentices to parties until they are 21 years of age, the Trustees retaining supervision over them. Power is given the board to arrest any inmate who has escaped from the institution. The course of instruction mapped out is very comprehensive and complete. All youthful prisoners now in the penitentiaries or workhouses of the State, under 18 years of age, are to be removed to the Reform Houses as soon as they are established.

LOUISVILLE MEDICAL COLLEGE. The Louisville Medical College held its annual commencement at Macaulay's Theater on the 25th ult. There were sixty-two graduates. The following received the honors: First honor, gold medal and appointment on the Resident Staff of the Louisville City Hospital, G. E. Gavin, Alabama; second honor, gold medal, to W. B. Dickens, of Mississippi; third honor, two gold medals, to James Hess, of Virginia, and Rufus C. Pennywitt, Ohio. The salutorian was Dr. J. C. Laurens, of Virginia, and the valedictorian Dr. E. B. Hardin, of Kentucky.

CHILDREN'S FREE HOSPITAL.—The "Hospital Circle" held its annual reception on the 27th ult. at the hospital building, it being the sixth anniversary of the cyclone, the Children's Hospital growing out of the necessities arising after that visi-

tation. The hospital was incorporated Oct. 16, 1890, and received its first patient Jan. 23, 1892. During the past year 120 children were treated in the hospital, with 5 deaths. Many times the capacity of the institution was tested to its utmost. The financial report shows that from various sources \$4,664.52 were received during the past year. The expenditures were \$4,489.86, leaving a balance of \$174.66. At present there are eleven endowed beds, \$2,000 endowing a bed; and there are eight supported beds, \$120 yearly maintaining a bed for that length of time.

KELLY.—Dr. Harris Kelly, son of Dr. Clinton Kelly, Dean of the Louisville Medical College, has been appointed physician to the Eruptive Hospital, vice Dr. C. T. Pope, resigned.

THE PUBLIC SERVICES.

CIRCULAR OF INFORMATION

For Persons desirous of enlisting in the Hospital Corps, United States Army.

The Hospital Corps consists of hospital stewards, acting hospital stewards and privates.

This Corps offers good pay and at the same time gives a training which will be of great usefulness in civil life. If promotion is in view, it opens the way to one of the best positions attainable by an enlisted man in the United States Army.

All enlistments are for the grade of private, but provision is made for the promotion of those who show themselves to be intelligent, capable, and trustworthy.

Original enlistments are confined to persons who are citizens of the United States, or who have made legal declaration of their intention to become citizens thereof. The term of service is three years.

Applicants must be between the ages of twenty-one and thirty years, unmarried, of good character and habits, able-bodied, free from disease, not less than five feet four inches tall, and able to speak, read and write the English language. Minor defects of vision that can be corrected by glasses are not regarded as a bar to enlistment.

They must defray their own expenses to the place of enlistment, satisfy the Recruiting Officer regarding age and character and be prepared to furnish evidence thereof. Their fitness for the military service can only be ascertained by examination at a recruiting station or at a military post.

Under the act of June 16, 1890, and existing rules prescribed by the President in accordance therewith, a man in his first enlistment, having served one year, may be accorded the privilege of purchasing his discharge at any time for several months thereafter, upon payment of a stipulated sum, the maximum purchase price being \$120.

The following is the rate of pay as now established:

GRADE.	FIRST ENLISTMENT.		
	Pay per month.	Pay per year.	Pay for three years.
Hospital Steward.....	\$15 00	\$540.00	\$1,620.00
Acting Hospital Steward.....	25.00	300.00	900.00
Private.....	18.00	216.00	648.00

In addition to the rates enumerated above, one dollar per month is added during the third year of first enlistment.

Members of the Hospital Corps reenlisting within three months from date of discharge receive a further increase of pay for the fourth and fifth years of service, and a still further increase for each five years of continuous service. They also receive from the Government (in addition to their pay) rations, clothing, bedding, medicines, and medical attendance. They can deposit their savings in sums not less than \$5 with any Army Paymaster, and for sums so deposited for six months or longer, interest at the rate of 4 per cent, per annum will be paid on final discharge. The deposits are non-forfeitable except for desertion.

For those who have become invalid during twenty years' service, or who have been discharged for wounds received or sickness brought on in service, a comfortable home is maintained in the city of Washington. The sum of 12½ cents per month is deducted from each soldier's pay, to be applied toward the support of the home. After thirty years' service enlisted men are entitled to be retired, and upon retirement to receive monthly three-fourths of the pay allowed to them by law in the grade they held when retired, with an allowance for clothing and subsistence.

Furlongs to deserving men are granted during the term of enlistment when their services can be spared from their post of duty.

When a man is honorably discharged at the expiration of his enlistment, or on account of sickness, his travel pay is ample to carry him to the place of enlistment. By care and economy he can save from his clothing allowances a considerable sum payable to him on his discharge.

The accepted candidate for enlistment is usually sent at first to a Hospital Corps School. He is there given the instruction that is needed to enable him to do his duty intelligently, and to appreciate what are the requirements for promotion in the corps. When properly qualified he is sent to some military station for duty.

Privates who have served one year or more and who have displayed particular merit may be recommended to the Surgeon General for examination with a view to detail as acting hospital steward. If a graduate in pharmacy, they may not be required to serve the full year of probation.

Under existing law promotion to a stewardship is not authorized until the candidate has demonstrated his fitness for the position by one year of service as an acting hospital steward. His application must be approved by the surgeon of his post and by the post commander, and

must bear satisfactory certification as to character, conduct, general fitness and habits, particularly in regard to the use of stimulants and narcotics. Successful candidates examined at or about the same time take precedence for appointment, so far as practicable, in the order of relative merit as shown by the results of their examination.

Applications for enlistment, accompanied by testimonials as to character, physical soundness and special knowledge (as of pharmacy, cookery, mechanics, etc.), should be addressed to "The Surgeon General, U. S. Army, Washington, D. C." (Who authorizes enlistments); or candidates may apply in person to any recruiting officer of the Army, or preferably to the medical officer of any military post or station.

GEO. M. STERNBERG, Surgeon General, U. S. Army.

WAR DEPARTMENT, SURGEON GENERAL'S OFFICE,
WASHINGTON, D. C., March 23, 1896.

Emergency Ration Board.—The Secretary of War has appointed a board of officers, consisting of Major Charles Smart, surgeon; Major Charles A. Woodruff, commissary of subsistence; Major Ernest A. Garlington, inspector general; Captain Louis A. Craig, Sixth Cavalry, and Lieutenant William C. Brown, First Cavalry, to meet in the City of Washington, D. C., March 31, 1896. The duty of this board is to examine the reports of the boards which were convened in the several military departments to consider the subject of an emergency ration, together with such views and suggestions as the Major General commanding the Army and the Commissary General of Subsistence may lay before it. The board is called upon to make recommendations on the subject and to report upon the minimum amount of articles of food necessary to sustain a soldier in health and activity for a limited period while in active service in the field.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 21 to 27, 1896.

Capt. Charles F. Mason, Asst. Surgeon (U. S. Military Academy, West Point, N. Y.), is granted leave of absence for two months and fifteen days, with permission to go beyond sea.

Major Curtis E. Price, Surgeon (Ft. Sill, Indian Ter.), is granted leave of absence for two months, with permission to apply for an extension of two months.

First Lieut. William F. Lippitt, Jr., Asst. Surgeon, will report in person to Major Henry S. Turrill, Surgeon, president of the examining board appointed to meet at Ft. Riley, Kan., on Tuesday, April 14, 1896, at 10 o'clock A. M., at such time as he may be required by the board, for examination as to his fitness for promotion.

The following named officers will report in person to Lieut.-Col. Charles R. Greenleaf, Deputy Surgeon-General, president of the examining board appointed to meet at San Francisco, Cal., on Tuesday, April 14, 1896, at 10 o'clock A. M., for examination as to fitness for promotion: First Lieut. Merritte W. Ireland, Asst. Surgeon; First Lieut. Benjamin Brooke, Asst. Surgeon; First Lieut. George M. Wells, Asst. Surgeon.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending March 28, 1896.

P. A. Surgeon B. R. Ward, detached from coast survey steamer "Blake" and ordered to the "San Francisco," holding survey on Chaplain J. J. Kane in London, en route.

Surgeon J. C. Wise, ordered to examination for promotion March 27.

Change of Address.

Butler, T. J., from 375 W. Monroe St., to 34 Throop St., Chicago, Ill.
Ferguson, H. Milton, from 291 43d St., to 40th St. and Cottage Grove Ave., Chicago, Ill.

Kaull, Wm. M., from Chicago to Princeton, Ill.
Nixon, J. W., from St. Louis, Mo., to Soldier, Kan.
Richstein, J. J., from St. Louis, Mo., to Evansville, Ind.
Ragsdale, E. W., from St. Louis to Lone Jack, Mo.
Ragsdale, J. E., from St. Louis to Chapel Hill, Mo.
Snyder, H. L., from Macungie to Old Zionsville, Pa.
Schurtz, Perry, from 110 Monroe St., to Pythian Temple, Grand Rapids, Mich.

LETTERS RECEIVED.

Alta Pharmaceutical Co., St. Louis, Mo.; Allport, Frank, Minneapolis, Minn.; Atkinson, W. B., Philadelphia, Pa.
Bloomfield, E. M., Peru, Ind.; Barnes, W. N., Baltimore, Md.; Bernd, Henry & Co., St. Louis, Mo.; Battle, Lewis J., Washington, D. C.; Berger, S. C., Philadelphia, Pa.

ADDRESS.

MEDICINE AND SURGERY OF THE QUEEN CITY.

Address delivered at the Unity Club, March 25, 1896.

BY JAMES T. WHITTAKER, M.D.

CINCINNATI, OHIO.

Cincinnati has always had an honored name. We have furnished our quota of statesmen, of soldiers, of artists and skilled artisans. We have had able editors, eminent jurists, eloquent divines. Ascending in the scale of genius, we had one astronomer and two real poets. If we have fallen short it has been in the trades and commercial life, for it is said that some of the railroads have put us on a side track, and one or two of the younger cities about us have left us behind.

But no city in this country has ever surpassed us in medicine. Perhaps there may have been times when a better sermon could be heard, or a higher legal opinion obtained in New York, or some other Eastern city, but there never was a time when a diagnosis of a disease could be better made or an operation be better done elsewhere than here.

DANIEL DRAKE.

Cincinnati had in the very beginning a good start in medicine. We have had some great men and women in Cincinnati. There were the Beechers, father, brother and sister; the Cary sisters, General Lytle, General Mitchell, Buchanan Reed. I asked a young attorney one day who was the strongest lawyer Cincinnati ever had. He said, Stanley Matthews. Though he was not exactly of us, Beecher was certainly the strongest preacher Cincinnati ever sent out. But the memory of neither of these men will live as long as that of Daniel Drake. His works are consulted now, to-day, and must be always by the medical historian and geographer as much as when they were written. The decisions of the just judge, broad as they may be, the appeals of the eminent divine, most penetrating and far-reaching when made in behalf of his country and in denunciation of slavery, are nevertheless forgotten in time with the occasions which gave them birth. But the facts which have been accumulated and compiled by the historian remain in perpetuity. Besides, Daniel Drake was a lover of this city and did more for it than any other single man. You should read what he says in his "Pictures of Cincinnati," published first in 1810 and afterward in 1815, when the town had a population at first of 2,500 and afterward of 6,000 souls. "Our Atlantic brethren will behold with astonishment," he says, "in the green and untutored States of the West, an equipoise for their own. Debarred, by their locality, from an inordinate participation in foreign luxuries, and consequently secured from the greatest corruption introduced by commerce, secluded

from foreign intercourse, and thereby rendered patriotic, compelled to engage in manufactures which must render them independent, secure from conquest, or even invasion, and therefore without the apprehensions which prevent the expenditure of money in solid improvements, possessed of a greater proportion of freehold estates than any people on earth, and of course made industrious, independent and proud, the inhabitants of this region are obviously destined to an unrivaled excellence in agriculture, manufactures and internal commerce, in literature and the arts, in public virtue and in national strength."

Drake had the light and airy temperament of the poet and like him was a true lover of nature. He could indulge in persiflage at times and strike true the chords which vibrate in every breast. You should read his panegyric upon the buckeye in a post-prandial speech, or hear him concerning our Indian summer.

"In the autumn of every year we have the period to which this term is affixed. It generally succeeds to rain or snow and severe frost; beginning in October or November and continuing for two or three weeks, with an occasional storm. But the atmosphere is, for the most part, dry, serene and smoky, through which the sun and moon exhibit in the morning and evening a face of darkened crimson. The verdure of the forest fades away, or passes into the countless varieties of brown, yellow and red, which give to the surrounding scenery a somber aspect. The occurrence of rain, with a northwest wind, at length suddenly dispels the gloom, strips the wood of its remaining foliage, and introduces winter with a transparent and cheering atmosphere."

There was difficulty with the water question then as now. "But a large proportion of all that is used is drawn up in barrels from the river. This is often impure and requires time to settle; but for most domestic purposes it is preferred to well water. The proprietors of the steam mill contemplate distributing water over the whole town; a plan so interesting that its execution will constitute an important era in our public improvements."

Whether the steam mill ever supplied the town or not the history does not state. But we know how deplorable is our lot to-day. Our Board of Administration has at last acted upon the recommendation of the physicians to make the attempt to get us pure water to drink. The physicians of this city have for decades of years labored to this end. Every human being in the city knows the necessity. We have been thrice threatened with water famine, and if we have got used to the mud, our visitors have not. Many of them will not even wash in it.

But the danger is not dirt but disease. In our long recent drought the ground absorbed all the sewage and we could drink the water with impunity; but when the first rains fell the surface impurities were washed

into the river, and in two weeks our hospitals and homes were filled with typhoid fever. Our deaths from typhoid fever alone gives us an unenviable notoriety over all other cities of our size. We find ourselves reduced to the necessity of buying a filter and paying to a foreign country the preposterous price of a dollar a tube for a piece of clay that is worth ten cents. And our poor people, the mass of the people, can not afford to own them. Fortunately they can protect themselves better by boiling the water. But they should be spared the necessity of such work. Beside, boiling kills only living poisons.

Our bad water represents our bad politics. The refusal to grant permission to construct new water works hitherto is the expression of a fear of exposing innocent men to temptation. I heard a man say the other day that it would be better to let the authorities steal a million or two than poison a whole community with typhoid fever and other such diseases. But this is not true. It is never better to compromise with that kind of evil. It is better to starve than to steal, and it is better to die of disease engendered by drinking excrement than to countenance bribery in any form. Physical is never so bad as moral corruption. All history shows that though a plague may desolate, it is immorality alone that can destroy a nation. Rome fell, not on account of the plagues, and not on account of the Goths and Vandals, but "because of the failure in the crop of Roman children."

Of course it is easier to condemn than to construct. Some one may ask me to suggest a plan that would be acceptable to the people. Well, I should say that a committee might be appointed in this way: As the first question is that of health, I would have one member a physician; to take care of the legal complication, I would have one member an attorney, and to look out for the business part of it, I would have one member a business man. I would have these members appointed respectively by the Academy of Medicine, the Bar Association and the Chamber of Commerce, and I would give them power to employ engineers, bacteriologists and other subordinates. As the politicians have made a failure of this business for twenty-five years, I would drop them out altogether. Therefore, my plan will find no advocates and will not prevail. Meanwhile, we will continue to drink each other's excrement diluted and die of typhoid fever, while our merchants and manufacturers will hold their annual reunions, and make speeches and congratulate each other on the proud position we occupy among the great cities of the earth!

Daniel Drake was before my time, but he was a great writer and writers are of all times. How well he depicts the chief source of satisfaction to an author, not in the approbation of the public, but in its effect upon himself when he says: "If this work prove a failure as respects public favor, the author will not be without his reward; for he has found enjoyment in the labor of producing it; and having confidence in its general accuracy, knows that it must stand as a great collection of facts, with which future and more gifted medical historians may work."

What modesty he shows in his apology for his work. To those, he says, who are experimentally acquainted with the difficulties attending the acquisition of elementary knowledge in chemistry, geology, botany, and the other physical sciences, without apparatus, with but few books, and no arranged collections, the author need make no apology. "But still it is the

sacred duty of every writer to improve rather than corrupt his language. The author performs, therefore, merely an act of justice to himself, when he declares that the imperfections in his style have arisen neither from indolence, nor contempt of public opinion, but from causes which lie beyond the sphere of his control; and, at the same time, it is equally due to the reputation of his fellow townsmen, that he should protest against the reception of this performance as a fair specimen of their literature."

Think of a man of the genius of Drake pleading that his work may not be taken as representative of the work of his fellow citizens in a town of 6,000 people, when he was himself head and shoulders above any other author of his day.

The distinguishing characteristics of great men are said to be, first, sensitiveness; second, imagination; third, industry. You may see how sensitive Drake was in apologizing for the character of his work. His industry is shown not only in the book he wrote about Cincinnati, but in the vast tomes he contributed to medicine. He was at various times connected with ten medical schools in different parts of the United States and actually founded two, one of them, his favorite, in this city. You may get a better idea of the range of his imagination in some of his predictions.

Dr. Drake was among the first adherents to the germ theory of disease. In the year 1832 he published in the *Western Medical and Physical Journal*, of which he was editor, a series of papers on Epidemic Cholera, which were afterward collected and enlarged into a small volume. In this volume he advocates the germ theory and adds that the "brief investigation given to the subject re-inspired my respect for an opinion long before expressed, that autumnal (malarial) fever and many other forms of disease might be of animalcular (germ) origin. . . . But I have had," he laments, "neither time nor means for experimental or bibliographical inquiry." One should read the ingenious views which he expressed in support of this hypothesis, which has since his day become established as a fact.

Drake had a parental fondness for the city of Cincinnati, and especially for the institution which he helped to form. Wherever he was, he says his thoughts went back to the city where, in the twelfth year of its settlement, he began the study of medicine, and in which, twenty years afterward, he had labored to found a medical college. In the pursuit of his studies concerning the diseases of the Mississippi Valley, it was necessary to make personal inquiry on the very sites of disease. "In journeyings by day, and journeyings by night, on the water and on the land, while struggling through the matted rushes where the Mississippi mingles with the Gulf, or camping with Indians and Canadian boatmen, under the pines and birches of Lake Superior, the image (of the city and the college) was still my faithful companion, whispering sweet words of encouragement and hope."

Thus Cincinnati has had in medicine a heritage to maintain. We are fortunate in having commenced right. Our medical history begins with a man singularly endowed with faculties of the highest order. He had no superior in the country then and we have not had his equal since. Our good forefathers did indeed entertain an angel unawares.

Yandell said once of Drake that his ashes in the cemetery of our city adorned it more than the palaces of our merchant princes. How true this is, and yet

how little it is known! But as in the days of old, when the gladiators entered the arena they had first to make salutation to Cæsar, so any medical man who thinks of Cincinnati thinks first of Daniel Drake, and the writer who would discuss the diseases of the Mississippi Valley must first pay tribute to the work of Daniel Drake.

GEORGE C. BLACKMAN.

I pass by now a procession of physicians, beginning with Goforth, Drake's own teacher, who had, Drake says, "the most winning manners of any physician he ever knew, and the most of them;" by Moorhead, an Irish gentleman of old stock, who died a baronet on his estate; by Reuben Mussey, who came to us from the East and who made a number of capital operations for the first time; by a number of lesser lights along which the eye glances, to be arrested suddenly by a large figure which looms up in the foreground in the person of George C. Blackman.

Blackman, as I knew him, was a man of magnificent build. He was a big, square, heavy-set, substantial man, with a solid tread. He must have weighed 200 pounds or more. His complexion was dark colored, his forehead broad and low. He had a heavy suit of coal-black hair which he would toss back from his face in a moment of impatience like a lion with a shake of his mane. His face was massive and square, his chin was heavy-set and firm, his eyes were large, dark and lustrous, his expression was singularly animated. He had a deep voice, a rich vocabulary and serious mien, which he could change to the light and playful when it threatened to become solemn. He had a singularly fine surgical hand; which expression is a tautology, as the surgeon is the *chirurgien* from *cheir*, the hand. I well remember with what peculiar admiration, almost veneration, we, his first-course students, used to regard that hand. His touch was firm and delicate. He could dissect a bone tumor from a blood vessel and graze but not cut the walls of the vessel. He could amputate a limb in a few seconds. As the boys used to say of another surgeon, "you must be careful not to wink while he does it, or you will lose the operation." And with what a pretty stage trick he would whip out a stone or flip out a bullet extricated from some recess in the body and send it rolling over the floor of the amphitheater amidst a round of applause from the students who could appreciate the delicacy and skill of the work. Ah! You must not think you have all the theatricals on your little painted stage. We have them every day in real life.

He had struggled with poverty, and won fame. Upon his first visit to London he had but \$75, and on this he managed to live several months—taking cheap lodgings, studying covered with bedclothes to avoid the expense of a fire, and by the dim light of a tallow candle; two penny-rolls a day constituting his food allowance. A fellow citizen once rescued him from starvation on seeing him gazing with hunger on the bread in a baker's shop. After a time he made the acquaintance of some of the hospital surgeons, among others that of Sir William Ferguson, who inquired at the close of the first interview where he was lodging. Soon thereafter he received a note from Sir William inviting him to dinner. He was fortunate enough to be able to borrow some clothes, his own being too much out of repair, and dressed in them made his way to the house of his host, where he was quite

abashed at being presented to some of the great surgeons of the day, among them Liston and Cooper, as a young American friend of whom he had spoken to them.

Blackman did best in the presence of a large audience. Like Daniel Webster, with whom he had some points in common, he could rise to an occasion. You may remember that Webster said when he got up to reply to Hayne on that memorable occasion when the fate of a nation hung in the balance, that he had a moment of trepidation, with a flash of recollection that his brother had fallen dead on a similar occasion, but that it instantly passed away, that he then felt his feet planted like rocks and that everything which he had ever read in history, literature, law or politics unrolled itself before him like a panorama. The points he wanted stood out illuminated in a glow of volcanic light. If he wanted a metaphor he had only to reach out his hand and grasp it as it went "smoking by." Blackman had a wonderful power in seizing upon the points of a case and presenting them strongly and forcibly; and he had such an extensive acquaintance with surgical literature that illustrative or analogous cases seemed to come as freely from his lips, as one of his colleagues said of him, "as the water gushed from the smitten rock." . . . "Behind all this was that bold self-reliance, the consciousness of power; he knew what he could do, and he knew that he would do it in the operation before him. No wonder that students listened to every word and looked at every motion of finger or knife with intent interest. His attainments in surgical literature were vast. Probably he had no superior on this continent in extent and variety of knowledge in this department. Several years ago, before Dr. Blackman came West," I am still quoting from Parvin's recollections, "the older Mussey, at a party of eminent professional men in the city of New York, happening to ask a distinguished fellow-surgeon the date and other particulars of the first performance of a particular operation, was answered: 'I don't know; but I will introduce you to a man who does know—Dr. Blackman—he is a walking encyclopedia.'" And he could talk while he worked as no other man could talk without working. I have never known a man who could surround an operation with such a glamour as could Blackman. Glamour is the correct term. He enveloped himself in it, and sometimes he blinded us with it to necessary technicalities. Blackman was the most gifted child of genius whom it has been my lot to know.

JAMES GRAHAM.

Our attention is next caught by a country boy, bright, alert, keen and shrewd, qualities derived from his Irish stock. His father was born in County Down, Ireland. His mother's name was Nelson and she was remotely related to my Lord Nelson. In a little sketch he once wrote of himself, he said that he remembered his mother's parents as being well educated, proud and aristocratic in their bearing. This was James Graham. He had that bearing too. When he came to us Graham was very poor. I remember him myself in a little office in Seventh Street which had a small back room, in which he took his simple repast, crackers and cheese, all he could afford to buy. He came to us friendless and unknown. He raised himself to the highest position that could be reached here in medicine, and held it with honor to himself and his profession for a full quarter of a century;

resigning it at last, under protest of all his colleagues because he felt that his day was done. One day in his early youth he stood up in a medical society and made a report of a case. His report was sharply criticised, and he defended himself with an ability in singular contrast with his age and experience. A few days afterward a far-sighted old physician, who was conducting a medical college, came to him and requested him to fill a chair in it. The students in the other schools thought it a joke, and they made up a crowd to go and give him a reception. They went down armed with paper balls and other such missiles of juvenile aggression. They came pouring in the door. Dr. Graham was just at his desk and was stopped by the noise. For a moment he was thoroughly confused, then straightening himself up he begged for a few moments attention. Forthwith he commenced his subject and as—stimulated by the opposition—he continued his lecture, he poured forth such a stream of simple eloquence as won every heart. Cheer after cheer went up as he closed. The whole class was won. In a few years more he was at the post he held for twenty years in the Medical College of Ohio.

The name of no teacher of medicine in this city has ever come down with such a bright halo about it as that of Dr. Graham. It is the universal testimony of students of medicine who have sat at his feet while he taught, that he had no equal as a lecturer on the practice of medicine. It was not that his vocabulary was so great. On the contrary, his words were few, but they were so perfectly clear and choice as to convey, with the greatest force, precisely what he meant to say. Dr. Graham was a master in the art of exposition. His style was perfectly simple. He stood straight as an arrow before his class, and spoke, at first gently, winningly, and then warmly, until his face glowed like a poet's, and music fell from his lips. But it was as a lecturer in clinical medicine that Dr. Graham stood head and shoulders above others. It was at the bedside rather than at the desk that he forgot himself in the subject being studied. It was indeed a rare privilege to hear Dr. Graham lecture on a case of heart disease, so systematically and succinctly could he make a diagnosis, and so clearly and convincingly establish the principles of treatment. Men who had been abroad and listened to the best clinicians of Europe, would say invariably on their return, "I have never heard the equal of Dr. Graham as a clinical lecturer." Profound scholars were abundant, more thorough pathologists everywhere, better clinicians none. Dr. Graham had in his prime a keen insight, a woman's intuition, a fine instinct, which enabled him to fix upon the disease at once, and he had, as only the children of genius have, the gift of making it plain to the commonest understanding. The country student fresh from the plow, and the college graduate fresh from the halls of learning, sat with equal pleasure and profit at his feet.

Ars celare artem. It is given to but few men to be able to dissociate themselves entirely from their work, and the ability to make the audience forget the actor is the characteristic of the consummate artist. Once it happened that the two greatest actors of Shakespeare's plays, Barry and Garrick, were playing the same piece, King Lear, in rival houses in London. The people crowded first to one house and then to the other, as such an opportunity to compare notes seldom happens. Some one asked the poet Rogers what

he thought of the two performances. Musing awhile, he said:

"The town has found out different ways
To praise the different Lears,
To Barry we give loud huzzas,
To Garrick only tears.

A king! ay, every inch a king,
Such Barry doth appear,
But Garrick's quite another thing,
He's every inch King Lear."

Such an artist was James Graham. He could incorporate himself in his work.

WILLIAM WIRT DAWSON.

During the sessions of 1848-49 and 1849-50 there sat upon the benches of the Medical College of Ohio a youth stoutly built, ruddy with the bloom of country life, endowed with a shock of dark hair, keen, brown eyes and an overflowing vitality, which burst bounds occasionally with an outbreak of mischief; yet withal a good listener, a quick observer and a boundless ambition. The name of this youth was William Wirt Dawson. He was registered from Ohio, his preceptor was his brother, and he graduated with a thesis on compression and concussion of the brain; which is to say that the young doctor had a taste for surgery rather than medicine from the start.

In the faculty at that time were famous men: John Locke, chemistry; L. M. Lawson, pathology and materia medica; M. B. Wright, obstetrics; R. D. Mussey, surgery, and king above all, Daniel Drake, practice. These men made the city of Cincinnati known all over the world. The valedictory address to his class of seniors delivered by Daniel Drake has become part of the medical history of this city. The valedictory of his own class was delivered by L. M. Lawson. It was an uncommon appeal to industry and stability of purpose. "Idleness is a moral imperfection; it debases, prostrates and ruins its victims." Again: "The great key to success in the pursuit of science is energy and determination." These were the words that made a deep impression upon this dark-haired young man, as he sat clutching his diploma and looking forward into fate. An old physician in the country said, once in my hearing: "I always knew that Dawson would get along. He used to work at his dissection sometimes until 4 o'clock in the morning." So the young man was soon handy with the knife, and he was soon familiar with the build of the body of man. The very next year, 1851, he was teaching anatomy in the Medical Institute of Cincinnati, with, as colleagues, Mendenhall, Wood and Comegys, the last survivor in the old galaxy. Within ten years after graduation the young anatomist, just turned of 30, had the chair of anatomy in the college of his birth. That was a proud period in his life, for "to have fame when young is the envy of the gods." He had as colleagues, Graham, Blackman, Bartholow and Wright, and was now winning his way to fame in surgery. When Blackman died the chair of surgery naturally fell to Dawson, and there are a thousand men now living who can testify how conscientiously he did his work. They will all say that Dawson was the most painstaking teacher the college ever had. The dullest student could still glibly recite the various lesions of fractures and not even the terrors of the green-room could frighten one of his pupils out of his knowledge of the dislocation of the arm and leg.

We have in Washington the largest and finest medical library in the world. Other nations may boast of

their works of art, their paintings and sculpture and architecture; they may surpass us in every field of literature and of science and in every collection illustrative of these fields. They have finer museums in natural history, finer libraries in every other department, but they can not surpass us in medicine. We owe that collection largely to the work of a man who got his medical education in this city and spent his life in collecting books. The Medical Library at Washington will always be a lasting monument to the labor and learning of John S. Billings.

But I am not to speak of him, or of other men who have gone out from among us, only of those whose lives have been spent with us. This splendid collection of books was packed in the walls of what was once Ford's Theater, the scene of a great tragedy in the history of this nation, a broken down building which finally collapsed and took fire and buried in its ruins a number of people. Fortunately, the medical library had been removed from this building and the precious volumes securely ensconced upon shelves in the fire proof structure, which is one of the many ornaments of our national capital. Now, it is not generally known that the work of securing the erection of this building was done largely by a congressman from the city of Cincinnati, to-wit, John F. Follett; who got the proper assistance from his fellows, or that the interest of Mr. Follett was excited by the unremitting efforts of Dr. Dawson, who being familiar with the inestimable value of the collection and having had impressed upon him the dangerous condition of the building, left no stone unturned in obtaining the coöperation of the proper authorities and securing the necessary appropriation for the new building. Thus was this building erected and the precious collections saved and made available for all time.

Dr. Dawson held every honor which medicine could give. He was one of the standard bearers of his clan. He was the soul of truth. He held quackery in abhorrence. He helped his fellows in distress. He was gentle to children, chivalrous to women, and upright and just in his dealings with men.

CORNELIUS G. COMEGYS.

Dr. Comegys, to whom I have alluded as the last survivor, has just died. He was the most beloved man in our profession, both in and out of it. Comegys was a big, broad man who had climbed, by hard work, to a point of broad survey. He had great ambition, and was busy with schemes day and night to such degree as to be regarded almost as a dreamer. But his ideas ran always in the line of progress, always onward and upward, and he kept his eyes so constantly fixed upon the goal as to be unmindful of the obstacles in his way. Some of his practical friends considered him visionary. He did really see visions, but always of things more perfect and pure than those by whom he was surrounded. Comegys was an embodiment of integrity, purity and truth. Like Schiller, he believed that every man has opened out before him two courses: one leads to the ideal, the other to death. But Comegys could never see anything but the course toward the ideal. By hard work and much self-sacrifice he made himself a fine scholar. And all his life long he strained his abilities to their utmost capacity in the service of his fellow man.

Hear him as he marks out the career of the physician: "We march with armies to care for the foot-sore and fevered soldier, and follow him, too, through

the thickest of the fire, not to aid destruction in her work, but to staunch the wounds she makes. It is not the trumpet call, nor the roar of battle that arouses our activity in the great conflict; but the cries of the wounded and dying—the appalling ruin of the field that inspires our enthusiasm amidst the dark splendor of war. The call of the distressed by night and day incites our energies and supports our weariness. Not only in crowded places, where the ways are easy, but in sparsely settled regions, amidst the sharp vicissitudes of the seasons, by lonely paths or in mountain defiles, unmindful of the tempest, we plod our weary way, the perturbations of our anxious hearts keeping time with the fret of the storm. On every hand, infirmity, sickness, helplessness, fearful casualties, bereavement, despair, death; hoping to strengthen, hoping to assuage or to avert, our days are occupied; sustaining the hopes, the agonies, the distresses of society, our responsibilities are momentous, our burdens are often too heavy to bear."

Hear him again as he pleads for the protection of the people against the frauds and wickedness of the quack. "When the human mechanism becomes deranged, and a great contest is set up between the forces of disease and the vital forces, who shall attempt to interfere—the man who has made these laws a study, who knows the operations of their final causes, who comprehends as far as science has shed light upon the subject, their special and general operations, or the man who is ignorant of the entire mechanism, and laying aside all such labor and investigation, attempts to rescue the suffering system by remedies which, according to his gross views, have been successful in a similar case? An irreparable injury, or even death itself may be the result of this ignorant interference, and what atonement then does the prosecution of an irresponsible man afford?"

"In regard to medicine, everyone" he continues, "must look out for himself. With the same indifference, we ought not to have a standard of weights and measures, nor a fixed value of coin, nor protection against issues of paper money. Let every one take care of himself. No man can assume to be a respectable minister of the gospel without the license of a church organization; no man can practice law without an approved examination before a court; no man can teach without a certificate of qualifications; no man can sell goods or peddle goods, or drive a dray or a cab, or an express wagon, without registering and a license. The public is defended from the impositions of the hackney coachman, but not from the quack doctor and patent medicine vender. No man is believed to be a carpenter, or a machinist, or a master in any other profession, unless he has served an apprenticeship to it. Then why, I ask, in the name of honesty and civilization, when we come to consider the human frame, the most wonderful structure of God, the divine idea of mechanism, in whose structure a thousand wonderful and complicated actions are in play, many of whose laws, after more than two thousand years of investigation, are still unknown, why, I say, do our governments surrender this beautiful structure to be prostituted to the mercenary practices of charlatans?"

A large part of his life was spent in an appeal for legislation to improve our sanitary conditions and to subdue the curse of quackery. He read, he plead, he labored for the creation of a Minister of Health in the Cabinet Department at Washington. He had

personal interviews with the President, and it is to the credit of the strong good man who now occupies this chair, that he listened to him with interest and was not unmoved by his argument. But it was thought that the time was not ripe. It certainly must come soon, and when it comes there will be general lament that the man who was best fitted to fill the place first, *in ad plures*, had gone before.

Comegys kept his youth to the last; he was interested in medicine to the very last day. "We must talk over the scheme of the University," he would say to me whenever I chanced to meet him. He could discuss any subject in medicine with any of the younger men, and with what freshness and philanthropy! In the discussion of the fresh air treatment of tuberculosis at the Academy, only yesterday it seems, he told the story of a young man who had recently consulted him. He had to say to him that his case was hopeless here and to advise him to seek change of air. "But," said the young man, "I have no means even to buy a street-car ticket." Dr. Comegys informed him that money was not necessary, that he should start and walk to Atlanta and beg his way. He would give him, he said, a certificate of his condition and everybody would help him on the road. He could travel like a German student on his *wanderjahre* and no one would refuse him food. "Silver and gold have I none, but such as I have give I thee."

Comegys had the pure spirit of discipleship. This is what he said once of one of his teachers and in the presence of him in a public address. It was in the last days of George Wood, and the occasion was a speech which rightly made him famous before the Alumni Association of the University of Pennsylvania. The Academy of Music was crowded with the *élite* of Philadelphia, for in that city the people still take deep interest in medical affairs. The old master sat on the stage, the central figure in a flood of light, but there was a shadow in front of him, the dark line of the scythe of the reaper, who was even then standing close behind his chair. "Venerable and remarkable man! Who, without ever laboring for fame, has received it; who, without ever climbing for great stations, has been lifted into them, and no man ever suspected his capability for them or envied him his well-merited success."

"Over a vast sea, beyond all storms," he continued with his apostrophe, "I behold a barque slowly moving through sluggish waters, borne so gently by the breeze that fills the stiffened sails that not a ripple breaks upon the heavy waves. Serenely stands the stately master at his post, steering for the last harbor. Somber and shadowy is the scene about him; yet across yon headland comes a rosy tinge of sheen, lighting up the tranquil face of the lone voyager who seeks the port of peace."

These are the men who for three-quarters of a century have borne the standard of medicine and surgery in the Queen City of the West. You may not point out in other fields greater purity of purpose, sacrifice of self, usefulness to others, than these lives have led, or show sentiments more sublime than these ideas have expressed. And the rank and file which followed, though failing from lack of opportunity or ability to express themselves in the same way, have led the same lives and held to the same ideals.

The memory of them inspires us. We, too, believe in necromancy as we know that wisdom and inspira-

tion come from consulting the oracles of the dead. It is as Ruskin said: "The grave is the best pulpit; the voice reaches farthest from the grave."

In contemplating the lives of these men the young physician may well be proud of his profession. When Correggio stood before a picture of Raphael, he cried: "*Anch' io sono pittore*," I, too, am a painter! And Byron, when he stood by the tomb of Galileo, exclaimed: "He was one of us."

There is in this city a band of men, mostly young men, who devote themselves wholly to helping their fellow-men in sickness and pain. For the most part, they have no motive in this work other than that of humanity and love of science. No other set of men may be compared to them in the disinterestedness of their work. Even the clergyman is sometimes sensitive about his particular faith; at least there is irreparable breach between the main divisions. The attorney must sometimes actually pervert the truth and try to defeat the ends of justice. Many of our statesmen have reversed the motto of Pitt, and work for themselves and not for their country. The laboring man works for nobody for nothing. He actually can not afford to, and he must charge for every moment of his time. The physician does much of his work for nothing; for years most of it.

These young men worked for humanity and science at first, but lack of appreciation and disappointment will change some of them. It is true that in after life the sense of the lack of appreciation is for the most part disappointed vanity, but it is different in youth. A few of our young men will persist and succeed without it, but some of them for lack of it will be reduced to the necessity of working for lower motives, will lose courage and zest in life, and a few, fortunately only a few, will strike their colors and betray their trusts. The fault will not be wholly with them; some of it will be with you.

If worth met with the same appreciation as wealth, what a stimulus it would be to virtue and invention! It should be so in a Republic. If it were so, how much more our civilization would surpass that in what we are pleased to call the effete monarchies in Europe. It was so in Greece, and the literature of Greece still rules the world. It is so still in medicine, for medicine is of Greek origin. If it were so in the world at large, what a support it would be to young men. But as it is they often see the prizes drawn by pretenders and quacks. If the young men see patronage going to quacks, what is the stimulus and incentive to work? Carlyle tells the story of a cobbler who was drunk all the time and whose wife and children suffered in consequence. But people patronized the drunken cobbler on account of his wife and children. Next door was an honest, thrifty, reliable workman, who had no patronage because he had no suffering wife and children. Finally, he became discouraged from lack of work and took to drink. There is everywhere vicarious suffering beside that which was endured on the cross. The patrons of quacks contribute to it. No person can take a front rank in any good society who patronizes fraud in any field.

The worst of it is that young men are, by lack of appreciation on the part of the public, discouraged from prosecuting scientific inquiry. See then how badly such neglect reacts. Bacon said long ago: "For in all times in the opinion of the multitude witches and old women and impostors have had com-

petition with physicians. And what followeth? Even this, that physicians say to themselves, as Solomon expresses it upon a higher occasion, 'If it befall to me as befall to the fools, why should I labor to be more wise?' And so is a community degraded. The people are prepared to regard an epidemic as a visitation of Providence. They are taught to look with distrust upon physicians. They are ready, without ever having seen one, to condemn vivisection, and many physicians themselves become only too ready to regard a disease as incurable. So inquiry is stifled and ignorance is exempted from disgrace.

Omne ignotum pro magifico, whatever is mysterious is wonderful. The crowd gapes with wonder at what it can not understand. The truth is, there is no subject concerning which man is so ignorant as the phenomena of nature about him. The mass of men have never been instructed in the physical sciences. Though they have the mind to comprehend they know nothing of astronomy, geology, chemistry, biology, and everything unknown is mysterious. But even people who have the advantage over their fellows in being somewhat informed upon these subjects, are ignorant of the construction and action of their own bodies. Consequently they, too, gape with wonder and are satisfied with the declaration that man is fearfully and wonderfully made. These people do not even understand that the study of anatomy, physiology, biology and *materia medica* rests upon the same laws, and that conclusions are reached in the same way as in the study of any other of the natural sciences. So that even intelligent people support quackery. A lawyer who will talk wisely about the capability of a witness, or who will sift testimony to the last point, does not hesitate to recommend a remedy for a disease, of the nature of either of which he knows nothing at all. As for the clergy, we are fast becoming acquainted with their physiognomies in the newspapers in recommendation of the virtue of quack medicines. So far as I have seen there are not more than two or three religious papers issued in the United States which do not largely subsist upon lies in recommendation of quack medicines.

Of all the studies of science, none is so difficult, so recondite as that pertaining to the body of man. The physician learns first, and as the most important lesson, caution. He holds in daily repetition the maxim of Hippocrates, *nil nocere!* whatever you do, do no harm. His new discoveries are all made first in the field of experimentation. He works with the lower animals, one after another, and after three or four hundred experiments upon the lower animals, he begins cautiously upon the body of man, often enough upon himself, and so establishes gradually first the safety and then the virtue of a remedy. What does the charlatan know about this difficult science of medicine? What does he know about the construction of the body, the uses of the various organs? What does he really know about the nature and action of the remedies? The truth is, he does not even care to know, and individuals of this brutality are allowed to practice medicine. If people could only know that the remedies in *materia medica* are selected with the greatest caution as a result of studies by botanists, chemists and biologists, that active principles are extracted in the greatest purity, and that only such preparations find their way into the *materia medica*, with what aversion and horror would they not look upon the crude mixtures of quackery, and with what recoil would they not regard the charlatans themselves!

The best botanists, the finest physicists, the most accomplished chemists, are ransacking every field of nature day and night to find something new in the treatment of disease. Why do the new rays fascinate us at once? Because we hope with them to see into the body of man. Do you think that if there was any virtue in any quack medicine the physician would fail to use it? "The cunning workman never doth refuse the meanest tool that he may chance to use." But he knows there is nothing in it. It is strange that a shrewd business man or a skilled artisan, who would look with disdain and contempt upon any pretense of discovery in his own field by men who know nothing whatever about the subject, will seize with avidity and will not hesitate to recommend some new remedy, though advocated with claims preposterous enough to be absurd. But the absurdity is not the least of it. The drug is dishonest. The man who makes the claim is the forger who passes counterfeits. If the truth were known every vendor of quack medicine is really liable under the law which imposes a penalty for obtaining money under false pretenses. No society can take high rank which offers its patronage to such men, and no government can prosper which puts its authority in such hands.

We have two classes of quacks, fools and knaves. To the first class belong the half educated, the dreamers, the metaphysicians, the fanatics, the individuals who practice according to a set dogma, who believe only in the administration of minerals or of vegetables, the speculators, the spiritualists, the faith cures, the pseudo-scientists. No advocate of any such branch of metaphysics can make his doctrines plain to any intelligent man. These are the people that believe that medicine cures by some secret dynamic principle, mysterious, undiscoverable, and of course undemonstrable, or who preach the arrant nonsense that a drug acts most powerfully in the smallest possible dose. All these quirks and cranks, and hundreds more that might be named, have their day. They come and go. One substitutes another. No one of these we now have, allopathy (if there be such a thing), homeopathy, eclecticism, vitapathy, or what not, will last another half century. But things similar, things false will always be, and the unmasking of any of them is a thankless task, because *populus cult decipi*, the people want to be deceived, and, as Emerson says, we do not like those who unmask our delusions. It is a strange thing that so many people will turn away from the light and prefer to grope in the dark, and that most men "will take no notice of what is plain before them, but will puzzle themselves in abysses which no understanding can fathom." As Carlyle says, our greatest business is not to see what is dim in the distance, but what is clear at hand. When these people see the truth they do not know it, or are so attracted by half truths as to be led astray. Sometimes, like Buridan's ass, in the midst of plenty they die of starvation because they can not see clearly enough to decide. Buridan maintains that if an ass could be put between two haystacks of exactly equal attraction, he would starve to death, as there would be no reason to prefer either one.

This is the class of people who wear us out with trifles and who make life a burden in drawing distinctions without a difference.

"People who could distinguish and divide
A hair 'twixt south and southwest side."

"And weave fine cob-webs fit for scull
That's empty when the moon is full."

And who spend hours in trying to determine

"How many scores a flea will jump
Of his own length from head to rump."

And this class of people, sometimes with the best intentions, do the most incalculable mischief, and all the more mischief because the intention is good. I often hear urged in support of some such a doctrine that the advocate was so earnest and honest. This fact only makes the doctrine more dangerous. "Nay, I believe," said Ruskin, "that metaphysicians and philosophers (speculators) are on the whole the greatest troubles the world has got to deal with: and that while a tyrant or a bad man is of some use in teaching people submission or indignation, the metaphysicians are always entangling good and active people, and weaving cobwebs among the finest wheels of the world's business: and are as much as possible by all prudent persons to be pushed out of the way like spiders."

If it could be known that the study of medicine is based upon natural laws and conclusions may be reached only as in the other sciences, there would be no room for the different so-called schools of medicine. There is really only one school, and that is the treatment of disease based upon a knowledge of the construction of the body, the uses of organs, the derangements which they undergo, that is, the diseases they suffer, the nature of remedies and the effect of remedies upon disease. That is, medicine is a study wholly according to natural laws, laws which are brought to bear in the study of all the natural sciences. These things are not matters of faith or belief, but of demonstration. True, the demonstration may not be made in all cases as accurately as in the arts and manufactures, because the human body is much more complex, but the effort must be made in this direction, and progress is possible in no other way. Studies in any other direction run into metaphysics, dogmas, isms, ologies and pathies. Not any one of these fancies has contributed anything to the treatment of disease. People think about the schools of medicine as about the sects of religion. But nobody claims that religion is a matter of demonstration. Religion is a matter of faith or belief. Medicine should rather be compared with law. There is only one kind of law, that which represents the wisdom of the ages. This law secures for us society, government, civilization: anything else is anarchy. There is only one school of medicine, that which is founded upon the study of the body, its diseases and the action upon them of remedies. Anything else is quackery. New systems of medicine, forsooth! Suppose a man, or a set of men, proclaimed to you that all your present ideas of astronomy were wrong, that the Heavens were covered in with blue flannel perforated and that what we take to be sun, moon and stars were only openings in the cloth for the penetration of light from the other side! What would you think of it? Well, that is exactly what is true of the so-called new systems of medicine. They are, if not open frauds, nothing but delusions of diseased minds.

Nevertheless, between the fools and the knaves, between the individual who is himself deceived and the individual who makes it a business to deceive others, there is a wide and deep gulf. Immeasurable indeed is the gulf between the men who blunder along knowing little but trying to do right, and men who purposely wreak wrong for personal greed.

The metaphysician is a man who is looking for a

grain of wheat in a bushel of chaff. We may regret the expenditure of so much time for so little reward, nevertheless, we may recognize that he is not off the track of virtue. We feel for him pity rather than contempt, and his efforts are greeted rather with a smile of amusement than with aversion.

How infinitely lower and more abhorrent is that class of men who see in human suffering only a chance of making money, and who do not hesitate to continue it and increase it by deceit and fraud, by the cunning of the quack and the brazen lie of the charlatan.

We come now to the class who live only upon lies. These are the individuals who make money by misrepresentation and fraud, and who actually speculate upon the sufferings of their fellow-men. Every community is infested with quacks, our community the worst of all, as our State has only just passed a law which protects the people against the vilest impositions of quackery, and this law as it stands is so little better than an indignity and insult to honesty and intelligence as to be endurable only on account of the promise of future good.

Sometimes the quack is an ignoramus who really believes for a time in the virtue of his preparation. But not for long; sooner or later the most stupid quack comes to know that his remedy fails. Nevertheless, he does not hesitate to plaster the walls, to publish columns in the papers, to fill the spaces in street cars and in every possible way obtrude his wares under the most gross and wholesale misrepresentation. His liniment will cure every case of rheumatism, his balsam every kind of cough, his salve will cure every sore, his bottle will in fact cure every disease. He can by the thousand furnish testimonials to this effect, and he can find people who have no other road to fame, who are willing to allow their faces to appear in the daily papers in recommendation of his wares.

Now, the fact is, everybody really knows these statements to be false. But so strong is the fear of interference with liberty of action that the quack is allowed to trade upon the sufferings of his fellows. People content themselves also with the belief that the remedy at least can do no harm; they say this especially of the infinitesimal dose. It must be remembered that the lie which is half truth is always the worst of lies. All falsehood degrades; every liar is an enemy of society, and the concealed enemy is worse than the open foe. A community may preserve itself only by turning its back upon every form of falsehood. It is not only the article of pure food and the pure drug which should be stamped with its proper value, but the brand should be put upon every kind of impurity. "The shortest way to check the downward forms of deceit is to set watch more scrupulous against those which have mingled unregarded and unchastised with the current of our life." If these patent medicines and quack medicines could be stamped with their true value, not one of them could remain, and if the individuals who now roll in wealth, some of them, could be punished according to the suffering they have caused, by commission and omission, they would be serving terms in penal institutions.

The people who believe that these remedies at least do no harm, forget that sins of omission are as bad as sins of commission, and that a remedy has control over a disease only at the start. A child can be protected against smallpox during the prevalence of an epidemic, only by being vaccinated within three days after exposure, or can be absolutely rescued from

diphtheria by the antitoxin only within three days after the onset of the disease. Most cases of consumption can be recovered from within three months. These opportunities are lost under the use of quack medicines. The vampire, in its original conception, was a dead man restored to life but without soul and with only life enough to suck the blood of its victim when asleep. In zoology the vampire is a bat which sucks the blood of persons and beasts when asleep. The consumption quack are the vampires which feed upon the slow tortures of this disease.

The true remedies of the materia medica are selected with the greatest care. A committee of the best men from the departments of medicine and pharmacy are chosen to supervise the purity of the preparation, to extract the active principle, to eliminate all crudity and impurity. This is never the case with the quack medicine. If the people could only know how vile are many of the preparations, how at least crude are many of the drugs, or even how cheap is the actual cost of the material, a few cents, perhaps, for which they pay a dollar, they could easily appreciate the indignation which exists in the minds of the men who know these things. And all the while the law in our country supports quackery. It is different in the older civilizations of Europe. The patent medicine must be registered, the exact composition must be given, and the people are thus protected against injurious preparations. Medical men owe it to their fellow-men: to drive these desecrations from the temple. The way is easy. It is only necessary to light up the dark holes with the blaze of truth. Let the evils of the remedies be shown up. The quacks are pretty quick to hide when pursued. In the presence of a real epidemic all quack remedies disappear. The "vitaline" craze ran over the whole of Russia a few years ago. Everybody was having themselves injected with this powerful rejuvenator and renovator. It was like the days of Mesmer. The streets were not wide enough to hold the vehicles of the people of fashion. They tried to persuade the Czar to have his son injected. Finally, they did experiment upon the body of General Gressner, who directly died from the effects. Then, when the charlatan was brought up for manslaughter, he took refuge under the employment of a dirty septic syringe, and when the nature of the remedy had to be disclosed to save his neck from the gallows, it turned out to be nothing but borax and glycerin.

You remember the St. John Long craze that ran through London a few years ago, and the editor of one of the leading magazines took it up. At last, when a great sloughing mass was formed, and a patient finally died of septicemia, and St. John Long was prosecuted for manslaughter, he hid himself from justice with the claim that his remedy was nothing but turpentine and vinegar.

Twenty-five millions of dollars a year are spent for quack medicines in this country! Some time ago it happened in this city that a rich man fell into financial distress. He wanted money and he wanted it quick. To protect himself from bankruptcy he must raise a large sum in three months. He had had some experience with quack medicines before. He picked upon a popular preparation of this class, and learning that it had not been advertised in three of our Western States, flooded the country with the imposture and made the necessary sum of money. But if an epidemic disease had been turned loose upon those innocent communities, if the hot breath of a pestilence

had passed over the land, it could hardly have done the people more harm.

Then, to say nothing of the actual physical damage, the injury to health, the breaking of spirits, the misery which goes with disease, look at the degradation of morals which results from a success of this kind. How wide-spread is the evil influence of fortunes made rapidly by fraud in any field.

And aside from the effect upon the health and wealth of a community and the general effect upon society, see the degrading effect of quackery upon the individual himself. Falsehood puts a brand upon the forehead of a man. He may wear his hat so low in public that the people may not see it, but some of his fellows know it to be there, and when he reaches the privacy of his own home and takes off his hat he sees it in his own face. He knows himself to be a charlatan; that is the worst of it. "Money answers everything, save a guilty conscience' sting." Emerson says that the time comes in the life of every man when all that he has he will lay down for right relations with his fellows. "Boss" Tweed was at the height of his power when he had bought the senators of his State at \$10,000 apiece and had himself surrounded with a crowd of sycophants and flatterers. But life had long since lost its zest. He had a disgust for it and for the parasites about him, and I doubt not that the Tombs were at last a not unwelcome retreat. The time comes in the history of these men, when, as Horace said of condemned criminals, Sicilian dainties will not please their palates and the melody of birds and harps will not bring back sleep. "Reputation, reputation, reputation, oh! I have lost my reputation. I have lost the immortal part of myself and what is left is bestial."

Witness also the degrading effects of quackery, even upon those who only indirectly or more or less innocently deal with it. Many of our drug-stores are stuffed from attic to cellar with quack medicines and patent preparations. And it is a notorious fact that where these products most abound the finest elaborations of the materia medica are not to be found. Some of the druggists, seeing the ease with which fortunes are made by these worthless preparations, are finally led to take a hand themselves. They do not hesitate to advertise Smith's sure cure for epilepsy, Jones' certain remedy for catarrh and Brown's infallible treatment for consumption. And so the druggist who has had the benefit of a classical training in chemistry, is degraded from a skilled pharmacist into a huckster, who not only handles, but recommends worthless goods; and our "honest apothecary" is not ashamed to advance claims which he knows to be false and to take money which he has not earned. Something of the degree of this degradation we learn in the bitter protest made by some of our druggists against the prosecution of the sale of impure drugs, and the insensible obtunding of the conscience is seen in the plea of a certain number to be allowed to brand and sell goods below the standard of purity.

If it could be that only the charlatan suffered, or the individual who believed in what he is pleased to call free latitude of medical practice, the effect would not be so bad. Perhaps it might result in good in securing more rapid extinction of this class. Unfortunately, however, the victims are found in the innocent members of the family, in the little children, upon whom the mischief is wrought both by commission and omission. Some time ago it happened that the

president of the Anti-vaccination Society of London lost his wife and all the members of his family, one after another, during an epidemic of smallpox. Thereupon the man committed suicide. There was general lament that the suicide had not been done first.

Twenty-five million dollars a year are spent for quack medicines! What could be done with that money if invested in medical education? What untold pains could be quieted, what unspeakable misery could be relieved! Look how a little money invested in the study of cholera in Prussia saved us millions a few years ago, and probably shut out cholera from our shores for all future time.

Would it be considered any justification for quackery that the fortunes which have been thus amassed have been used to build churches, erect hospitals and endow orphan asylums by men

"Who think for life-long evil to atone
By building monuments in stone?"

Is it possible to merit heaven by making earth a hell?

Look now upon this picture and then upon that! On the one hand fraud, deceit, degradation, perhaps with wealth. This is the quack. *A monstrum nulla virtute redemptum.* On the other hand purity, self-sacrifice, the highest philanthropy, perhaps with poverty. This is the true physician.

One of his pupils said of Parkes that he never followed him about the wards without feeling that he could become better, with an intense wish to be so, and Romney, the artist, declared that if he wanted to make a representation of the compassionate benignity of the Saviour he would paint the face of the elder Guy. "There is to me," said Sala, "an inexpressible charm in the lives of the good, brave, learned men whose only objects have been and are to alleviate pain and save life."

Look now upon this picture then upon that! The mission of one brings him nearer to the gods; the acts of the other are close to those of the fiend. On the street, in common parlance, they are all doctors. Will you not at least help us to draw the line? Into the hands of which men will you commit the medicine and surgery of the Queen City?

ORIGINAL ARTICLES.

THE MECHANISM AND DIAGNOSIS OF TRAUMATIC CEREBRAL LESIONS.

Read at the Second Annual Meeting of the American Academy of
Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY JOHN W. PERKINS, M.D.

SURGEON OF THE UNION PACIFIC R. R.
KANSAS CITY, MO.

In this paper I wish to review the mechanism by which traumatic lesions in the brain are produced, and the means by which an exact diagnosis of the seat of the lesions must be made.

Until recently it has been considered justifiable for the surgeon, after having made a gross diagnosis of fracture of the base, "compression" or "concussion," to stand by and see his patient die, or become the subject of epilepsy, insanity or permanent paralysis. Medical literature is filled with cases illustrating the natural results of these injuries, following the "expectant" treatment. From them, one quickly learns how slowly and imperfectly nature repairs the lesions, and how far reaching are the after effects. Some have

questioned whether a cerebral injury is ever completely recovered from.³ The evidence is now complete, that various forms of insanity, in many cases, originate in and are directly caused by a neglected injury to the brain. This has long been known of epilepsy and various motor and sensory disturbances. In a recent paper read before our Jackson County Medical Society, I reported in detail ten cases of cerebral injury, showing forms of mental derangement, from simple loss of memory, to persistent irritability of temper, melancholia, delusional and moral insanity and mania, all the direct result of intracranial injury. Most of these were due to old injuries; some submitted to operation and were relieved, others not. But the recital of the cases was not so much for the purpose of calling attention to the results of late treatment, as to the fact that symptoms of such nature had resulted from an unrepaired intracranial injury. To show how infrequent interference is in these cases, I need only quote the statistics recently furnished by one of the best hospitals in the country.¹

In six years, 308 cases of severe head injury were treated with 115 deaths. In twenty cases fragments of bone were removed and in 24 cases only was trephining done. Eighty-two of the cases were characterized as "Fracture of the Base," of which 60 died. Three of the 82 were trephined, two without success and the third was successful in opening into the seat of the hemorrhage, but the vessel was not secured and death followed in twenty-one hours. No report is made as to the condition of those who survived. Thirty-two cases, excluding the gunshot cases, came to autopsy and showed extradural hemorrhages in thirteen, which the report comments on as "a larger proportion, of localized extradural hemorrhages than is generally appreciated."

I can not dwell on the necessity of repairing at once and as completely as possible, the effect of an injury to the brain or its coverings. All will I think, acknowledge the desirability but question the ability to locate most of the lesions when recent, and even if located, to relieve them. Apparently little effort has ever been made to get at the basal extradural hemorrhages which comprise such a large proportion of the fatal cases. These extravasations remain fluid for hours after an injury, and the suggestion is directly at hand, that the pressure could be taken off a well localized mass by a carefully directed aspirating trocar or needle introduced directly through the brain mass, as well as by an opening at edge of base and separating the dura. It is not my purpose however to enter into treatment.

It must be acknowledged that the exact diagnosis of recent intracranial lesions often presents a most complex problem. The real difficulty does not lie in the interpretation of symptoms, for these are often complete and conclusive in their indications, but rather in the lack of data furnished by an unconscious patient. There are facts however which may be obtained under the most disadvantageous circumstances, and these are sufficient in the majority of cases to lead to a correct diagnosis. It is always to be kept in mind that the absence of symptoms is as significant and possesses as much logical force as their presence. Also that the brain is not unlimited, hence a localization by exclusion in the absence of a direct diagnosis, is permissible.

Let us take first the mechanism by which the lesions are produced, and then the resulting symptoms with

special reference to their localizing value. The first effect of a blow is received by the scalp, which may be cut, bruised, lacerated, or when protected, may show no evidence whatever of a serious lesion beneath. It is always to be carefully examined for such evidences as it may furnish. It is the most direct avenue for infection, leading to important and often disastrous secondary changes, and on that account is worthy the most painstaking care of the surgeon.

The effect upon the cranium is determined by the force of the blow, and the curve, thickness and density of the bone. The character of the injury can often be inferred from the nature of the accident. In a general way it may be said that it is dependent on the velocity and concentration of the force. When the velocity is great, and the force is concentrated, the effect is most marked at the seat of impact, as when a bullet strikes the skull. But when the force is disseminated and of slow velocity the effect is generally most marked elsewhere, as when a man receives a blow from a sand bag.

With the exception of the fracture at point of impact, which may be depressed, cranial fractures are linear and almost invariably run toward the base, following the curve of the shortest radius and in the line of least resistance. That this is not invariably true is due to the fact that in some instances the force is so applied as to force the fracture to follow a long curve, as in compression of the skull from the sides. The so-called fractures by *contre coup* are no longer to be considered possible.² The only way in which the skull can be injured on the opposite side, is by injury against a resistance which is really equal to a second direct blow. This applies to the brain also, which is often injured by being bruised through its impact against the skull.

Most of the linear fractures have no importance in themselves, and it is unfortunate that modern surgery still classifies head injuries under "fracture of the vault," "fracture of the base" etc., as though these were important. The close association of such structures as the facial nerves, the middle meningeal artery and branches and the sinuses makes it necessary to estimate as closely as possible their direction and extent. It should also be borne in mind that extensive fractures can not be received without grave injury resulting to the cranial contents as a result of the same force which produced them. But a depressed bone in itself does no harm, were it not for the injury it inflicts on the parts beneath. It is the brain and its nerves which are of importance, and which must be considered from first to last. This has been formulated in the statement that "all cases of head injury should be estimated primarily with reference to the amount of damage which the cranial contents have received, and secondarily with reference to their becoming involved."³

The brain is a soft solid, permeated with tougher blood vessels, and poised on a water bed over a very rough and irregular base. This water bed of cerebro-spinal fluid surrounds the hemispheres and is continuous with that in the spinal cord. At the base of the brain, it varies much in depth, owing to the irregularities forming the so-called lakes. Inside the brain the ventricles are filled with the same fluid, and each blood vessel in the brain is suspended in a double lymph space also filled with the same fluid. Between the muscularis and adventitia of all isolated arteries is the adventitial lymph space of Robin, and outside of

this, between it and the limiting membranes is the perivascular space—or space of His. Any increase in the size of the vessels takes place at the expense of the fluid in one or both of these spaces—and as the skull is a closed box, it is conversely true that anything which displaces this perivascular fluid, must be attended by an increase in the size of the vessels, or rupture. Moreover not only the nerves but the nerve cells themselves, lie in spaces filled with the same fluid which connect with the perivascular spaces.

The fluid on the outside of the brain is directly continuous with that in the spinal cord, but that of the subarachnoid and intra-ventricular spaces is only communicable through the small foramen of Magendie at the fourth ventricle, the so-called cerebro-spinal opening. It is this cerebro-spinal fluid which plays the most important rôle in traumatic intracranial lesions.

The other factor is the elasticity of the skull as a whole. This varies greatly from infancy to old age, but must be most marked in the young adult skull with firmly united sutures and a large amount of animal matter in the bones. If dropped from a height on the floor such a skull will rebound like a ball. The interosseous membranes prevent the infant's skull from having the solidity necessary for such a rebound, and the brittle bones of old age break too easily, so that the problem varies somewhat at the extremes of life. It has been shown by Felizet⁴ that the adult skull, when struck a moderate blow, yields under it, forming what he calls the "cone of depression." It is similar to what occurs in a billiard ball or a bell when struck. The blow compresses the billiard ball in one diameter and it lengthens in the transverse. As it rebounds the long diameter becomes the short one and the short one lengthens, and this continues, the alterations becoming continually more feeble until the force is spent. This causes in a bell what we call its tone, which is long drawn out because its edge is accurately round and hangs free so that nothing interferes with the vibrations. But in the skull the effect is necessarily of short duration, the vibrations being quickly interrupted by its buttresses, irregularities and attachments.

Under these premises, what happens from a blow on the head? Let us say for simplicity, that it is not sufficient to produce a penetrating wound. Under the blow the skull is momentarily depressed—lengthens in the transverse diameter, and rebounds, becoming elongated in the diameter in which the blow is received. The bone may or may not be fractured. If depressed beyond a certain point it can not rebound and we have a depressed fracture. The fissure in the bone may involve vessels or nerves in close connection with it, leading to immediate hemorrhage or paralysis. The sudden depression of the skull drives the cerebro-spinal fluid forcibly from under it, and superficially it must spread laterally into the areas where the diameters are elongated—and what is not thus accommodated is forced into the perivascular lymph spaces, or forcibly injected into the spinal column.⁵ This explains how we can have a lesion of the spinal cord from a blow on the head. The quick rebounding of the skull tends to leave a vacuum at the four diameters where the maximum of motion has been, *i. e.*, at the point of the blow, diagonally opposite and at the two points at the extreme of the transverse diameters. Now the impetus given to the cerebro-spinal fluid is such as to send it out of the way, and the reflux of the fluid is relatively slow, so

that we have the vessels left without support, and they give way under the strain at the four points mentioned. Thus are accounted for the extradural and sub-dural hemorrhages.

That which happens in the brain is exactly analogous to that which happens in the cerebro-spinal fluid lying outside. The impetus of the blow received on the vault tends to drive the fluid from the larger ventricles into the smaller, from which there is no escape except through the small opening of Magendie.

All the perivascular lymph spaces receive the same impetus, and momentarily the blood vessels and nerves are unsupported; thus occur numerous minute inter-cerebral hemorrhages into the nerve sheaths, which are found as constant factors in cerebral injuries. The sudden intense distension of the fourth ventricle often results in rupture of its walls. In this way are accounted for the well-known glycosuria which so often follows cranial injuries; also cases of immediate death from laceration of the vagi at their roots. The rush of the fluid through the foramen of Magendie into the spinal cord is sufficient to irritate and often to lacerate the restiform bodies in the bulb. It has been experimentally found that mechanical irritation of these bodies, produces a reflex anemia of the brain, attended with all the symptoms of the so-called "concussion."

Also the evidence of many autopsies points to them as the seat of the fatal lesion, so that the conclusion is irresistible that the opisthotonus, spasms, rigidity and other symptoms joined together under the name of concussion, find their explanation in the irritation of the restiform bodies, by the cerebro-spinal fluid as it is violently injected into the spine.⁶

The brain mass itself, deprived of the protection of the cerebro-spinal fluid, is lacerated at the site of the blow, and on the opposite side through its own impetus against the bone. When the impulse is downward, it is found that the resulting injury against the jagged projections in the base are not more marked than against the smooth and rounded vault. These act like the elastic falx and tentorium which are stretched like sails in different planes between the cerebral masses, and take up a large portion of the force, directly preventing the impinging of the proximal half of the brain upon the distal portion and against the opposite bony wall. It is interesting to note that the tentorium is ossified in some animals, whose brains are built on the fore and aft plan, *e. g.*, cats.

All possible primary lesions thus consist of, 1, the fractures in the skull and rupture of nerves or arteries and sinuses in close connection with it, with their resulting hemorrhage; 2, lacerations of the cerebrum, basal ganglia and the underlying nerves; 3, hemorrhages into the brain substance, nerve sheaths and basal ganglia and edema of tissue adjacent to those parts pressed upon. Of these three sets of lesions, localized hemorrhages upon the surface are in the majority of cases the cause of death or permanent injury, and statistics show that a majority of them can be reached if located. The secondary lesions comprise unorganised blood clots, cysts, hematoidin deposits, collections of colloid bodies, cicatrices, miliary scleroses, adhesions, varicose veins, and last but not least, the secondary infections, pyogenic and sarcomatous.

I wish to-day to consider the symptoms from primary lesions only, *i. e.*, the fractures, lacerations and hemorrhages which we see in a recent case. I wish

to repeat that the linear fractures are of little importance beyond indicating the possible source of other lesions.

The inference to be drawn from immediate facial paralysis, hemorrhage from the ear and a true sub-conjunctival hemorrhage are too obvious to be repeated. The depressed fractures interfere with or suppress the functions of the portion of the cortex pressed upon and demand immediate attention, not with a view to restoring the skull, but wholly with reference to the underlying brain. There is no such thing as a depressed fracture without symptoms, unless you suppose that there is a portion of a man's brain without function. It may take time and study to demonstrate them, however. The effect of the lacerations and hemorrhages depend upon their situation and extent. A laceration may cause immediate and total abolition of function at the site, through the severing of the nerve connections of the part. The phenomena resulting from a hemorrhage, and the mechanism by which it acts, are best seen in cases where a small vessel is ruptured and a considerable time occupied in the development of symptoms. Slight at first, it irritates the abutting cells and the normal action of these cells is manifested peripherally in response to the stimulation. If into the motor area, involuntary twitchings or spasms of a muscle or group of muscles may result. As the hemorrhage increases in amount, it presses upon the cells, and driving out the intercerebral fluid prevents the circulation of blood and lymph through the part pressed upon. From the irregularities of pressure upon the vessels, a halo of edematous tissue invariably forms around the compressed area. This area is bloodless, therefore without function, and this loss is manifested peripherally. It is not to be seen by looking at the compressed area. The resulting symptoms comprise all possible motor and sensory disturbances, mental and moral aberrations according to the parts pressed upon. A good example of the varying effects of pressure from hemorrhage is seen in the eye symptoms resulting from rupture of the middle meningeal artery.⁷ At the outset the eyes twitch toward the side opposite the lesion, and remain there with contracted pupils and often constant nystagmus until the pressure is sufficient to cause a paralytic lesion when the eyes roll toward the side of the lesion, the pupil on the side of the lesion dilates and the paralysis is complete. The importance of a hemorrhage depends upon the nature of the tissues pressed upon and the degree of pressure. A mass the size of a pea, suddenly extravasated into the medulla may be immediately fatal, while a pint of blood may be slowly and harmlessly spread over a hemisphere with a few recognizable symptoms.

A depressed fracture acts like a localized hemorrhage in the cortex and is equivalent to the introduction of a foreign body into the cranial cavity.⁸ From it the general cerebro-spinal pressure rapidly rises and gradually falls, leaving the depressed area anemic in the midst of an area of edematous tissue which rapidly forms.

From the local pressure there results a general difference in the temperature of the sides of the body.⁸ When the compression is slight, the opposite half of the body (*i. e.* the paralyzed half) shows an axillary temperature distinctly higher than that of the other side. Whereas, when the compression is considerable, the reverse is the case, and the opposite side has a

lower temperature than that on the same side of the lesion. It has been suggested as a working hypothesis to account for these facts, that a small pressure produces an irritative lesion of the inhibitory mechanism of the vaso-motor center supplying the opposite side of the body, and so a dilatation of the cutaneous vessels it produces, causing a rise in the surface temperature. A greater pressure produces a paralysis of the inhibitory mechanism, so that the vaso-motor center acts without restraint, constricts the vessels, and leads to a fall in temperature. This point has not yet been fully worked out, but may be of considerable importance when fully developed.

A local compression of the cortex also causes characteristic changes in the pupil.⁸ If the compression is small, an irritative lesion apparently results and at the same time, as the temperature of the opposite side of the body becomes elevated, the pupil of the same side contracts and reacts poorly to light. When the

compression is greater (the opposite temperature falls) the pupil of the same side dilates, while the opposite pupil contracts.

When the pressure becomes great enough to considerably affect both hemispheres, the opposite pupil will also dilate.¹⁰ Dilatation of the pupil primarily on the same side as the lesion was described thirty years ago by Mr. Hutchinson,⁹ and has since been known by his name, and the "Hutchinson pupil" has become familiar as a sign of hemorrhage from the middle meningeal artery. The phenomenon was supposed to be due, by Mr. Hutchinson, to the gravitation of the blood toward the base and its pressure upon the third nerve. But recent experiments have developed that pressure at that point is not necessary to produce the phenomenon. Furthermore it would be difficult to explain on this hypothesis, as Mr. Dean points out,

how it is that only the fibers of the third which go to the iris are paralyzed, while the other muscular branches are not. It would appear that any cortical pressure, at least in this region, is sufficient to produce the dilated pupil.

Beside the alteration of the pupil referred to, which is really a paralysis of the muscular fibers of the iris, we may have as eye symptoms: 1, paralysis (and spasms) of the ocular muscles; 2, alteration in the field of vision; 3, incoördination of the parts concerned in the act of vision in each eye singly. In order to understand the ocular symptoms it is necessary to know a little of the central visual apparatus. The movements of the external muscles of the eye are controlled by the third, fourth and sixth nerves, and this motor mechanism "is finely bilateral but the sensory mechanism is badly unilateral,"¹¹ and hence of much greater localizing value. This unilateral disposition affects not each eye singly, but the lateral halves of both eyes. Taking first the muscular apparatus, and the third, fourth and sixth nerves: If we turn our eyes to the right or left it is done by the double synchronous action of the internal rectus of one eye and the external of the other. This is the physiologic process known as conjugate deviation.

FIG. 2.—Diagram showing external surface of left hemisphere. R, Rolando; S, Sylvius.

Definite relations do not appear to exist between any one part of the motor area and the ocular movements. Irritation of the whole cortex as well as the visual area occasion ocular movements toward the opposite side (conjugate deviation) and these movements are greater, the farther the irritation is removed from the macular region of the visual area. The fibers from their cortical nuclei are collected and rearranged and coördinated at the top of the pons Varolii and pass out thence together, coming into close relations again in the neighborhood of the cavernous sinus and the sphenoidal fissure.¹² The only portion of the cortex which seems to have a definite ratio to any of the muscles about the eye is a portion of the anterior central convolutions in front of the face area (Fig. 2). Pressure at this point causes a falling of the upper lid (levator palpebrae superioris) on the opposite side from the lesion. The connection of the basal motor ganglia with the cortex of the cerebrum is as yet uncertain, but the fibers pass down in the anterior part of the internal capsule and through the pyramidal tract to the neighborhood of the third nerve where they cross. As the internal recti are supplied

by the third and the external by the sixth pair, a limited lesion in the pons may result in separating conjugate movements into its elements.¹³

A considerable lesion in the pons will produce a wide spread ocular palsy.¹² And the farther away from the pons the lesion is, either cortically or peripherally, the more limited will the paralysis be. Lesions above the pons and in the cortex produce physiologic paralysis *i. e.* of associated movements of both eyes. Lesions below the pons will paralyze single nerves and their corresponding muscles. Excepting that a lesion at the cavernous sinus and sphenoidal fissure may take in a group of nerves but affecting one eye only. And this paralysis will be crossed with any body paralysis which may be present: To summarize: Conjugate deviation of the eyes, accompanied by twitching, spasms or other irritative symptoms, is indicative of a lesion in the cortex on the opposite side to the deviation. Conjugate deviation accompanied by paralytic symptoms, dilatation of the pupil, indicates a lesion on the side toward which they deviate. Irregular or partial conjugate deviations and wide spread palsies indicate a lesion in the pons. Monocular palsy may mean a lesion anywhere between the eye and the basal nucleus, but if more than one nerve is implicated, the lesion may be near the sphenoidal fissure, or in the

is known as homonymous hemianopsia. It may be caused by a lesion anywhere between the chiasm and the cortical visual center, but practically for our purpose it is necessary to consider only the cortex lesion, as any hemorrhage large enough to interrupt the conduction in the optic tract would be otherwise immediately fatal. Wilbrand's test is of use here in case of doubt. A fine pencil of light is directed on to the paralyzed side of the retina; if the pupil contracts, the lesion is cortical; if it does not, it is in the optic tract. Central vision in cases of hemianopsia is usually unimpaired, the macular center being apparently double and common to both eyes.

In rare cases the lesion may be so placed as to involve a portion of the macular center, thus causing incoördination of the visual images of one eye and

FIG. 3.—Diagram showing mesial surface of left hemisphere.

cavernous sinus. Ptosis results from paralysis of the third in its course or pressure on the anterior central convolution.

In the sensory act of vision, two orders of central apparatus are involved, whose relations are best understood from the diagram (Fig. 1). The optic nerve divides into three parts which go to the pulvinar, the anterior corpora quadrigemina and the lateral corpora geniculata. These are usually spoken of as the primary visual centers. These are in turn directly connected with the cortex of the occipital region of the cerebrum called the secondary or half vision centers (Fig. 1c). As was said in speaking of the motor mechanism, the sensory mechanism is "badly unilateral," and is connected with, not each retina singly, but the corresponding halves of both retinae. This I believe is made clear in the diagram.

The same distinction is to be found here as elsewhere between irritative and paralytic lesions. If the lesion in the visual cortex is slight, the irritation is manifested in subjective sensations of flashes of light, of colored fire, etc., and may be referred to the opposite eye, or may be common to both eyes. A lesion large enough to suppress the function of the cortex is manifested by a loss of vision in the lateral halves of both retinae on the side of the lesion. This symptom

FIG. 4.—Showing course of fibers from motor tracts. V, lateral ventricles; L N, lenticular nucleus; C N, caudate nucleus. Between them the internal capsule.

giving rise to monocular diplopia. The inference from this symptom is immediate and direct as to the implication of the macular center. The sensory eye symptoms must be looked for. It should be remembered that a paralysis of the left side of both retinae means that right half of the field of vision is involved.

Leaving the eye we come to the motor apparatus, of which the centers have been well differentiated. They are grouped around the fissure of Rolando and can be best shown quickly by a diagram (Figs. 2 and 3). The location of the leg, arm and face center, eyelid, speech, hearing and smell are accurate, and any paralysis or spasm of cortical origin will appear on the opposite half of the body. The fibers from the cortex are collected, pass through the internal capsule into the crura cerebri, thence into the pons where the facial portion crosses to the opposite side (Fig. 4). The

arm and leg fibers pass on into the medulla where they cross over. Somewhere between the cortex and the crus cerebri, probably in the internal capsule, the sensory fibers join the motor, but their centers are as yet poorly worked out. A lesion in this part of the cortex is often purely motor. Lower down the lesion must involve sensation.

When the lesion is above the crus cerebri, we have the ordinary crossed paralysis of the face, arm and leg; but from the crus down we may have one or another of the alternate paralyses combined with a lesion of the cranial nerves in most instances.¹² There may be 1, paralysis of the face, arm and leg on the opposite side to the lesion and of the muscles supplied by the third nerve on the same side; 2, paralysis of arm and leg on the opposite and face on the same side; 3, paralysis of the arm and leg on the opposite and of the muscles supplied by the seventh and sixth on same side; 4, paralysis of the arm and leg on the opposite side and the face on both sides; 5, paralysis of face, arm and leg on the opposite side, and anesthesia (from paralysis of the fifth) on the same side of the face; 5, paralysis of the arm and leg on the opposite, and the tongue on the same side. It is important to keep in mind the significance of the cross paralyses. What has been said of paralyses applies equally well to spasms.

So much for connected facts regarding the possible seat of lesions. There remain several disconnected facts, which are often of great significance. The first of these is the hyperpyrexia often attending a hemorrhage into the pons. The screaming fits which result from irritation of the posterior portion (testes) of the corpora quadrigemina and the incoördination of movements following pressure upon anterior portion of the quadrigemina are worthy of note. Pressure upon the middle lobe of the cerebellum also produces incoördination especially in the legs. Vomiting which is so common in head injuries has some localizing value. In the vast majority of cases it is a pure reflex caused by pressure or irritation of the membranes of the brain. It may be also caused by direct implication of the vomiting center in the medulla from which the vomiting is usually active and persistent. In ordinary cases it is to be taken as indicative of a surface lesion, and its frequency may be roughly used in connection with other symptoms in estimating the degree of intracranial pressure.

Similarly manifestations of pain point to a surface lesion as was pointed out by Mr. Hilton many years ago. But all manifestations of pain are apt to be suppressed quickly by the rise in the intracranial pressure. It is a valuable localizing symptom however when present. The retraction of the head and neck, associated with incoördinated movements, mechanical yawning, low temperature, slow and feeble pulse and especially jerky uneven feeble respiration are characteristic of hemorrhages into the cerebellar fossa.

Unconsciousness commonly follows severe head injuries immediately. If it does not pass off in a short time it means an increased intracranial pressure, probably from hemorrhage. If it passes off promptly and after a short lucid interval the patient becomes again unconscious, the diagnosis of hemorrhage is certain. Associated with paralytic symptoms and dilated immobile pupils, it is indicative of excessive intracranial pressure, probably from hemorrhage, and demands immediate operation, if only to relieve an edematous dura in the absence of definite localizing symptoms.

In conclusion it may be said that the cerebral centers are not to be considered as sharply defined in their relation to the body but as spots of maximal relation whose functions merge into and are directly connected with those of other centers. The cerebral centers are not related to the body like the keys of a piano to its strings, but rather as the keys of an organ which by its stops may bring forth many combinations in harmony with the pipe which corresponds to a given key.

DISCUSSION.

DR. JAY— I do not know of any paper that could be more interesting and more positively demonstrated. The paper deals with positive facts and can be demonstrated, and the thing to do is to take up these facts and to become so familiar with them that we can make the diagnosis and the consequent treatment according to the laws laid down by the paper. That is all I can say about it. It can not be discussed.

THE PRESIDENT—The paper certainly is very exhaustive and very instructive.

DR. GRISWOLD—The applications to be made in practice of this paper are of extreme importance. Going back as far as 1858, I recall the first case that I had in injury of the brain that might have been saved if I had known as much about brain injuries as the doctor does.

A man had received a blow on the temple, just over the frontal bone, near the coronal suture, from a wine bottle. He was a hack driver. He drove sixteen miles that evening, stayed at home, drove back the next day, and the next night could not drive home. He was delirious, had considerable fever and a good deal of pain. He was brought home and I was called to him in the night. There was a little contusion, no depression, and the man was sick, and kept sick till he died two weeks afterward. He had some diarrhea during the disease, there was no paralysis, and the effort was made to say that he had typhoid fever: I stopped that. When I made the post-mortem examination I found the inner table of the skull had been fractured which ran across the meningeal artery, and had produced an extradural affection between the skull and dura mater, which led down over the root of the eye. General meningitis spread from that point and death resulted. If we had appreciated the situation and trephined, we might have saved the man.

Some twenty years ago I was called to a consultation in regard to a boy who had received a blow transversely across the skull by the edge of a board. The boy was struck down, but there was no wound on the scalp and no apparent injury. He did not, however, seem to be quite able to get up. He had a doctor attending him, and I dare say it was four days before I was called to see him. I could not see any special marks of brain injury. The eyes did not work exactly together. He had no pain. Three or four days later I was disposed to make a crucial incision at the seat of the blow and was permitted to do so, and found a depressed fracture, with considerable pressure on the brain. No other symptoms of brain depression, but there was a depressed fracture and several pieces of the bone loose. I took out the loose pieces and elevated the remainder and the boy got well and is well now. He was then 12 years

of age; he is now married and has a family. Never had signs of epilepsy or anything of the kind. I always thought if I had not done that operation he would have been an epileptic.

Three years ago last Christmas I was called in consultation to another case on a man who had been down in a shaft forty feet and a barrel was let down, striking him on the side of the head, smashing his skull and producing quite a wound. The doctor who was called to him on Friday—Christmas was on Sunday that year—did not do much, as he was a young doctor and did not know very much about such things. There was not much paralysis. The wound was over the frontal convolutions, down rather in front of the fissure of Rolando, but involved the speech center. I was called to him Sunday morning and found there was an excessive congestion over all that side of the scalp. I took out probably to the amount of $2\frac{1}{2}$ square inches of skull, all smashed up. The dura was torn open, the speech center was involved, so that a great deal of brain substance came out during the operation. I supposed he would be seriously affected in speech. He got well, and strange to say, he can talk now tolerably well. He lives in Colorado, near Sterling; his name is Shaw. There is a great deal of wound covering there on the skull, and the skull is affected. If he speaks and sneezes you can see the brain bulging out. He never will be worth anything for business, but still, if life is worth living, he has got it.

The doctor's demonstration specializes a great deal more than was necessary in these cases: these did not require so much specialization, except perhaps the first. In 1858, if I had known a little more about the brain, I would probably have trephined.

DR. HENRY HATCH, of Quincy, Ill. —In connection with injuries to the brain I wish to speak about a case that I had about eight months ago, as illustrating that it is not well for us to lose sight of a case after an injury. It was a railroad employe: he had the superior portion of his scalp lacerated from a falling brick, and a lacerated wound a little to the right of the median line. I examined the wound and found no depression of the skull whatever, and supposed he would get along all right by dressing the lacerated wound. It healed without any suppurative or any untoward symptoms, and I supposed the man would get well. About five weeks later pain developed in the region of the wound and it became necessary to open it up, trephine, and I found the inner table of the skull depressed and fractured, while the outer table showed no marks of depression whatever. After this operation he recovered without any more trouble.

DR. HENRY W. COE, of Portland, Ore. The writer of this paper, Dr. Perkins, says that we can remember regarding the centers and diagnosis in these cases if we have some charts handy about the office. I think it would be a good thing after this paper is published, to have this paper in our offices so that it would be convenient for reference when required. It is worked out very carefully, and this subject is somewhat recent. The pathology of injuries of this kind, and the histology of the nervous system is of such a recent date, so far as it has been worked out on any scientific basis, that a paper of this kind is one that this Academy can well be proud of. I am glad to see the doctor note the symptom of pain, and the case just related is in point. We often have injuries of the head in which there is no depression that we can determine, but in which there is a great deal of pain, which continues after the pain from the contusion of the scalp passes away, and I think in all those cases we should explore a portion of the skull. In such cases there is undoubtedly some displacement of the inner table wherein pressure is exerted through the meninges upon the cortical substance beneath. I have seen a case on my way to this meeting, and on which I shall operate on my way home, in which there is practically no depression, at least no depression determined, but there is intolerable pain,

following an injury occurring some years ago. No doubt in this case there is some inflammation, following a fracture of the inner table and some inflammation of the dura. In fact, there may not even be an apparent fracture, merely a slight bulging inward of the tabula interna sufficient to produce the lesion. Where there is some pain, there is generally some dural trouble. The doctor referred to hemianopsia following injuries in certain localities, but he did not mention the fact that we sometimes have this condition in case of a sanguineous patient. We sometimes see this in cases where there has been no head injury, and sometimes we think perhaps there has been hemianopsia there, and yet in some cases where this condition exists temporarily, stimulation will relieve the case. The doctor has no doubt seen a case of this kind but I do not remember hearing it mentioned in the paper. We know that we have that condition of women in labor, where there is a large flow of blood and which perhaps in twenty-four hours passes away, or else passes away quickly under stimulation.

DR. COLE—I feel that Dr. Perkins has placed us under obligation for this remarkably clear elucidation of a very important subject. The study of cerebral topography and cerebral localization and the practical results to be gained from the knowledge of the physiology of the brain and the facts as brought out in the paper, are comparatively recent and are of the utmost importance. Those of us who have practiced a dozen years or more remember with what almost horror we looked upon the prospect of opening the skull. In this day of clean surgery we do it with impunity. We operate for symptoms which a dozen years ago were blind and we can operate with accuracy and we can get positive results. I feel that the Academy owes its thanks to Dr. Perkins for this very able paper.

DR. HATCH—I want to say just a word in line with what Dr. Cole has said, and to go perhaps a little further than the author of the paper has recommended. He said that in simple linear fractures without symptoms of compression, it is as well to pay no attention to them. I believe from experience in quite a number of cases in which I have trephined, that in the majority of cases of simple linear fractures, you will find an infused clot underneath the fracture pressing on the dura, and I believe that the impunity with which we can trephine and enter the skull anywhere on the dome of the skull, has shown us that it is good surgery to explore in every one of those cases. The fact is, in those cases of recovery it is only a week or ten days until they are comparatively as well as they always were. It seems to me good surgery, in absence of other symptoms there than symptoms attending linear fracture, to trephine and find out what you have. I have just got through a case which has recovered which shows that one should not despair in very extensive fractures of the skull. About two months ago a colored man was thrown from a wagon upon the curbstone and fractured a portion of the skull $3\frac{1}{2}$ inches in diameter, lacerating the anterior frontal sinus. The hemorrhage was very extensive; I had him conveyed to the hospital as rapidly as possible and it looked to me as if the case were hopeless. I removed about $3\frac{1}{2}$ inches of the anterior portion of the cranium and caught up the anterior frontal sinus and ligated, and the man is around town to-day apparently as well as ever.

DR. PECK—I would like to detail one case I had six years ago. It is that of a boy of 14 who was employed in the iron mines to drive mules which brought the cars of ore out from the mine. In reaching in to uncouple the chain links between the cars, his head was caught between the projecting beams on the two cars, and by the impact of the cars going down grade behind and jamming them together, the head was caught in the space between the two beams, which afterward by measurement was found to be $5\frac{1}{4}$ inches. I saw him within twenty minutes or half an hour, found a depressed fracture of the left parietal bone at its middle portion just above the ear. The depression,

which was very plainly made out, consisted of two fragments wedged down on the brain, the soft surface of the meninges. The hematoma covering the field of the pressure was pulsating synchronously with his heart, and it was with a good deal of fear that I made an incision. I feared I would have a troublesome hemorrhage before I could trephine and remove one of the fragments of bone in order to get to where I could control hemorrhage. However, on making the incision there was just one gush of an ounce or so of blood, and no further hemorrhage. It was an absolutely clean operation, the pulsations having been transmitted from the brain substance itself and communicating through the triangular openings above and below the angles of the fracture. It was quite a slow operation, cutting out the first fragments of bone, inasmuch as they were wedged down in the shape that it took a great deal of lifting force to get out the fragments of the bone. The symptoms which the boy presented were a semi-unconsciousness, some vomiting, unequal pupils, symptoms of partial compression. I removed one of these fragments of bone, elevated the other, and that boy never had a rise of temperature above 99.6, and in eight days after the injury was out playing ball. There were three lacerations of the meninges; there was an escape of a teaspoonful or more of cortical substance; there was absolutely no functional trouble; there were no symptoms following the injury save that he has a depression in which you can lay a finger.

DR. DANIELS—I feel that we are largely indebted to Dr. Perkins for this instructive paper. I rise to differ from Dr. Peck in regard to miscellaneous trephining in linear fractures. I do not quite favor that, but I do believe that age should have very much to do with all operative measures in that direction. I have found in my experience that children or very young people will bear considerable depression or a great number of linear fractures without any bad symptoms at all, while persons of middle age or beyond, having comparatively the same injury, will have very serious results follow. In adults the use of the trephine is almost imperative. I believe that the consideration of age in these cases, so far as I am able to judge from experience of a considerable number, covering perhaps two hundred in the hospital where I am associated, is an essential one.

DR. JAY—We all admit that in young persons you can have a depression of the skull and probably have no spasms and no paralysis, but experience will tell you that in after life they are sure to have them if the depression is left. I have operated on several cases, twelve, fifteen and twenty years ago, and for years afterward there would be no unfavorable symptoms, but about the time of puberty they would appear. One case is a woman, where the depression remained and afterward required trephining. It is not good surgery to delay trephining.

DR. PECK—Dr. Jay misunderstood, I did not refer to depression; always trephine where there is depression.

It was moved by Dr. Peck and seconded by Dr. Maynard, that the thanks of the Academy be extended to Dr. Perkins for his elaborate and learned paper. Carried.

DR. PERKINS—I wish to thank the Fellows for their very kind reception of the paper, and also to speak of one or two things that have come up. First, in regard to those extradural hemorrhages. I have recently received a report of 160 cases that were done in one hospital by one group of men acting together, and out of those 160 cases, 64 were cases of extradural hemorrhages from the meningeal artery in brain injury. As this is nearly 40 per cent. of the cases, one is justified, perhaps, in cases of an unconscious patient, without any symptoms, in going inside the meningeal artery rather than see the patient die. You will have forty chances in one hundred of relieving him. The basal hemorrhages are more rare and diagnosis is more difficult. The treatment of

basal hemorrhage would be more difficult than the diagnosis but it has often been suggested in my mind how easily we could relieve, in a fresh case of basal hemorrhage, if we knew where it was, by a simple insertion of a hollow needle down through the cerebral mass. We often insert a needle into the brain substance in search of an abscess and no harm is done, and I see no reason why we could not put a hollow needle into the basal hemorrhage if we could know where it exists. It would not be necessary to raise the brain from the base of the skull. In regard to the magnitude of certain injuries, it has been stated by one authority that there was no brain injury so great but that it could be recovered from, and none so small but what death might result. The most terrible wound I know of was in the case of a man who was struck by a tamping iron, which passed through the malar bone and passed out through the cortex. I have seen the tamping iron; it was a very heavy bar, and went lengthwise through the skull and produced a very terrific injury. The man recovered and has all his faculties, as far as known.

In regard to the position of the speech center, and the loss of certain portions of the cerebral matter we know that the speech center lies in the third left frontal convolution, but it has been found that after the loss of it, its function is taken up by the opposite side of the brain. There is a certain interdependence of the brain from one side to the other, which is used in this case, and so paralysis of speech, permanent paralysis, does not result.

In regard to exploratory operation in simple linear fracture, I do not believe in operating for nothing, and if there are no other symptoms present, I doubt if one would be justified in interfering. One operates for symptoms, not for nothing.

PERSONAL EXPERIENCE IN SPINAL INJURIES.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY J. F. PRITCHARD, M.D.

DISTRICT SURGEON C. & N. W. RAILWAY,
MANITOWOC, WIS.

The question of spinal injuries has been so much discussed that one feels like apologizing for presenting anything more on the subject, but as it is yet vital in some measure, we must continue our investigation until we have an approximation to the truth.

In going over my records, carefully kept for many years, involving every case of injury on one line of road, I find that an average of injuries to the back was thirteen per thousand. These include all classes of injuries, and are noted on my reports as contusions, sprains, twists, and injuries which are popularly called concussions, also dislocations, fractures and serious injuries of like nature to the spinal column. But what is remarkable is that of these injuries caused by falls, blows, or other like causes incident to railway life there was but one in which recovery was not complete and permanent. My experience would therefore tend to show that so called railway spine is a myth. In reporting cases, I limit myself to those that had marked symptoms.

Case 1. P. S. Cooney, aged 19: Irish-American, good habits, a freight brakeman, was standing at a switch at a small station to close it as the train passed out of the siding. The ground was slippery and wet, when he, in some way not very well explained, fell under the caboose. He claimed that the wheels ran diagonally across his hip and the lower lumbar region, which statement was corroborated by his conductor who claimed to have been standing on the ground with his lantern and saw the accident. I think they were mistaken, as the car had switch ropes, chains, links, pins, etc., the usual complement for such cars, which would add about 3,000 pounds to its weight, and would no doubt have killed him instantly. My

theory was that he fell in such a position as to go through under the brake-beams and truck-frames, probably doubled up. He no doubt was run over in some such way. When first examined, in an hour or two after receiving the injury, I could find no marks on his body, *i. e.*, no wheel mark or contusion. The spines of the upper lumbar vertebrae were fractured and displaced laterally to a slight extent. He complained of little pain, was totally unable to move his body or legs; had no loss of sensation other than a numbness; no paralysis except as above noted, which seemed to be only an inability to move temporarily. He had full control of bladder and bowels, took his food well and had no rise of temperature at any time. In the course of a few days he complained of a soreness of the muscles with external tenderness over the whole region below the point of injury. This condition improved gradually. He was discharged and resumed labor as flagman on a passenger train, having lost seventy days' time. When discharged his general condition was very good. He had perfect use of all of his muscles and no other difficulty except a slight deviation of the vertebral spines.

Case 2.—Lucian Budyszcz, age 18, Polish laborer, was run over by a caboose which he and a number of others were endeavoring to push out of a side-track by hand. The switch was open and a switch engine coming through the yard at the rate of fifteen miles an hour, struck the caboose and injured several men. Budyszcz's injuries were multiple and complicated as follows: Right elbow and forearm laid open, requiring resection; comminuted fracture of left femur; injuries to his toes, requiring amputation of two or three; dislocation or fracture of all of the fingers on both hands; injury to the spine similar to Case 1, *viz.*, fracture of spinous processes in lumbar region. He complained from the beginning of severe pain in his back, and required large doses of morphia to relieve the pain which lasted nearly two weeks. There was no paralysis or loss of function of any organ, and recovery was complete so far as the spinal injury was concerned. The other injuries healed kindly. He was under my charge about six months, until a settlement could be made with him. He never complained of any spinal symptoms afterward.

Case 3.—R. Kroll, age 28; German, foreman of a gang of track layers, who when going and returning from work used two ordinary hand-cars. They frequently raced on returning, and at the time of this accident were racing. A wheel broke while they were running at a high rate of speed, throwing the whole crew forward in front of the car. One man was killed instantly, another received slight injury, while the subject of this sketch fell under the car and was caught at the junction of the last dorsal and first lumbar vertebra in the gear of the car, causing a dislocation. He was immediately paralyzed from this point downward. We operated later and reduced the dislocation by carefully dissecting free the attachments of the spinous processes, then by making lateral traction on the opposite spinous processes with extension from his feet and shoulders, the dislocation was easily reduced. The spinal canal was not opened. He did not require an anesthetic for the operation, and said he had some return of sensation afterward. He died two weeks later. In this case, while we did not have the privilege of a post mortem examination, it was quite evident that the cord was completely or nearly severed.

Case 4.—John Adamski, Polish, section foreman, age about 40, was attempting to remove his hand-car from the track to clear a special train. The car was struck and he was thrown off, causing contusions of the lumbar and sacral regions which appeared to be muscular only. Later when seen by the writer he complained of nothing but weakness when stooping, no pain or difficulty in walking, no loss of sensation nor any apparent nerve lesions. When the case came into court, however, he had evidently been coached, as he then complained of great pain, loss of use of his right leg, curvature of the spine and in fact everything which would indicate a serious spinal injury. His physicians testified that they found an angular curvature in the lumbar region with contraction of the leg, etc. By order of the court we examined him carefully. Measurement showed no loss of substance in the leg as compared with the other. We placed him horizontally on his face and in a few minutes his leg became straight. On examining the spine, there was not the slightest deviation from normal. It was an evident case of malingering. The court also took this view and granted a non suit.

With these exceptions all other cases reported as injuries of the back did not develop symptoms referable to lesions of the spinal cord. In cases 1 and 2, while there were marked symptoms of injury of the cord, recovery was as prompt and complete as could

be found in any other region or organ of the body, leading me to the conclusion that while injuries in this region may effect the cord, unless there be some prior disease or tendency thereto, we need not anticipate permanent injury.

All court records with the subsequent history of the patient will bear out the above conclusion, and I am fortified in my belief by discussing this subject with anti-corporation attorneys. It has not fallen under my observation to see a case of railway spine, yet there may possibly be such a condition, or rather an imaginary condition while the claim is being prosecuted, which disappears as soon as the judgment is paid.

I find attorneys out of court agree that so-called railway spine is a humbug, and notably in one case in which a prosecution was brought for an alleged injury of this nature caused by the derailing of a sleeping car. The attorney confessed to me that he did not believe that the woman was hurt at all, but said that she was diseased, of bad character generally, and he could bring his action best for spinal disease. He said if he had a similar case again he would set up some such state of affairs as this, that she was in such a condition of health that a shock or fright, or similar disturbances would destroy the general equilibrium and cause incurable disease, but under no circumstances would he ever bring suit for railway spine again. I am satisfied that in healthy systems an injury to the spinal cord will cause one of two conditions, either immediate marked symptoms, from which recovery is likely to occur, or when the cord is destroyed, permanent but immediate loss of function of all parts below the point of injury. I do not think in a healthy system the concussion to this region is more likely to produce permanent injury than will a simple uncomplicated fracture cause permanent loss of function of a limb.

MASTOID DISEASES.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons held at Chicago, Ill., Sept. 25-27, 1895.

BY A. D. BEVAN, M.D.

CHIEF SURGEON ICWA CENTRAL RAILWAY,
CHICAGO.

I do not know of any other field of surgical work which involves such a thorough knowledge of the parts involved as mastoid diseases and its resulting complications. I would say that I have here a number of specimens selected from a lot of work which I did during last winter; I operated on thirty-five cadavers, made seventy operations on both sides of each cadaver in this line of work, to determine some of the points in regard to the anatomy, especially the position of the facial nerve with relation to the sub-medial triangle, and to demonstrate the best method of entering the temporal bone and the cerebellum and the sigmoid portion of the sinus.

From experimental work which I did, following very closely in the line of Macewen and Kerner, I determined the points which are practically laid down by Macewen in regard to the opening of the mastoid antrum. The key to the entire situation is the mastoid antrum, and a successful opening of the mastoid antrum can always be made if we adopt and follow these simple rules. If we examine the skull carefully we shall find immediately behind the temporal ridge the posterior border of the zygoma, a ridge running into the temporal ridge. This ridge is the upper line

of a triangle known as the submedial triangle. If we select the upper portion of this triangle as our point for opening the mastoid antrum, immediately below the posterior root of the zygoma, we shall find thus a point about a quarter of an inch behind the external auditory meatus and its roof. Now, if we place a dental bore, which is the best instrument to open the mastoid, or a fine chisel in this direction and open in the direction parallel with the external auditory meatus, we will invariably open into the mastoid antrum. The mastoid antrum is constant. Very often we do not find mastoid cells, but we invariably find a mastoid antrum. The depth varies very much indeed. Sometimes we will find it at the depth of a quarter of an inch, sometimes as deep as five-eighths of an inch from an external surface of the bone, but the landmarks are constant. Now, in order to avoid the important structures in this vicinity, we must understand the exact position of the facial nerve and of the sigmoid sinus. The facial nerve is, as you are all aware, on the posterior wall of the external auditory meatus, running over the facial bone, entering at the internal auditory meatus, it runs first forward and a little upward, until it reaches the stylo-mastoid foramen in the bone; it then makes a right angle turn, then a second right angle turn and comes out. But the simple anatomic fact to remember is this, that the facial nerve is in the plate of bone, between the external auditory meatus and the opening which you have made into the mastoid antrum. Now, that is very important, because you find the statement made by some specialists in ear work (I have seen the statement made several times) that in their mastoid work they first open the mastoid antrum, then they chisel away the posterior plate of bone. If they do this they will cut the facial nerve every time. It would be the greatest luck in the world if the facial nerve was not cut off, but it can always be avoided if the operation is made in the way I suggest.

Another point: Beside the facial nerve, the position to avoid is the position of the sigmoid sinus. I have drilled here an opening into the sigmoid sinus, a large opening with a trephine at this point, but the sigmoid sinus can practically always be avoided. It is possible that is hardly a fair statement to make, because the best practitioners have opened up the sigmoid sinus in work of this kind, but in work which I have done in the dissecting room there was no difficulty whatever in avoiding the sigmoid sinus. The exact position of the sigmoid sinus you can determine by drawing a line from the articulation of the lower and external angle of the parietal bone to the typical mastoid process. The upper two-thirds of the line will give you very plainly the position of the sigmoid sinus. It is a point which might very often be necessary to determine; in an ordinary mastoid case it would not be necessary to open it. Where we suspect thrombosis, the common thing would be to extend our operation downward and outward, after opening up the mastoid antrum, and expose the condition of the sigmoid sinus. Some of the best work which has been done in this line has been done by Von Bergmann, who makes a very neat suggestion in this work. His routine work is this: First, opening the key of the situation, the mastoid antrum, then if there is intercranial lesion, open up a portion over the point just about the position of the temporal sphenoid, removing that plate or working it down and

exposing the dura mater: then with a spatula elevate the dura mater and from this work backward over the interior surface of the temporal bone. More than a majority of the cases are in the temporal sphenoid alone and a majority are through the dura mater.

Von Bergmann's routine of work is, to open into the mastoid antrum, then to expose the temporal sphenoid alone, if the difficulty is found there, as it is in two-thirds of the cases. If, however, he does not find the difficulty at that point, then he extends the operation from the mastoid down over the sigmoid sinus. If he does not find the difficulty at that point, and there is evidence of intercranial lesion, he extends the operation in the same line. These four operations, mastoid antrum to sigmoid sinus, is an extensive operation and you should go from one point to another until you determined the circle.

One interesting point developed is the fact that following mastoid disease without involvement of the temporal sphenoid lobe or cerebellum, patients have died from sepsis, from a septic thrombus in the bulb of the jugular vein. Just at the point of division there is quite an elevated portion of the vein which extends upward, the bulb of the jugular vein, which has been found in several cases to be the seat of septic thrombus and the effects of general sepsis and death.

Another interesting point in connection with this kind of work is the necessity of ligating sometimes the jugular vein. The work in this direction has as yet been limited and I do not think sufficient in number or exact enough in all of the cases to determine the exact value of the ligation of the internal jugular. Personally I do not think it is a good method, unless we can actually demonstrate lateral sinus thrombosis and possible involvement of the internal jugular, because you may have, as has been reported, a case in which the internal ear was like this: The patient had sepsis, and it was found that the septic material had blocked up the jugular above the point of the ligature and had been carried in from the other radicles.

My own work in this line has been rather limited. I have to report a number of cases which illustrate the value of this work. I do not believe, however, that I shall take up the time of the Society. There can be no question but that a large majority—that is putting it very safely—a large majority of intracranial lesions can be successfully combatted by early and properly performed operations. Macewen's work, which is the best work that has been done on this subject, shows that out of some twenty cases, he saved over 70 per cent., even after involvement had begun. But the great value that should be recognized by every physician, is the prevention of intracranial lesion. How many times would a simple mastoid operation prevent intracranial lesion? Any one can do a mastoid operation with a knife and gimlet, if he knows the simple anatomic rules which will enable him to open the mastoid antrum itself.

DISCUSSION.

DR. GRISWOLD—I do not think we ought to let the paper of Dr. Bevan pass without consideration. He mentions the work as comparatively of the same degree with appendicitis. Appendicitis has advanced much farther in its course in the profession in general than the disease of the antrum of the ear. I recall a case that I think might have been cured if we could have followed Dr. Bevan's advice. Some twenty years ago I was consulted by a young man who had pain in his ear. He had been more or less deaf and had had discharge from his

ears since infancy. At this time he was suffering continuous pain and occasional discharge. I turned his case over to an aurist, and in the course of six or eight weeks he died. In the meantime, before he died, the pain got more and more aggravated accompanied by a slight rise of temperature, not considerable, not much increase in pulse and not much mental disturbance and no paralysis: he got a little dull and stupid for the last four or five days of his life: it was pretty difficult to make him understand anything. He did not hear very well with his other ear, but it did not seem as if the disease of which he died caused a great deal of functional disturbance, and I was bound to make a post-mortem examination. I found an abscess, large enough to fill a good-sized teacup with pus. The inflammation seemed to have gone through the roof and affected the dura mater and at last an abscess had formed. The mastoid cells were considerably infiltrated and showed signs of disease, and I have not very much doubt but that the case might have been cured with the advanced surgery that Dr. Bevan teaches now, and that he died for want of good surgery.

THE WOODBRIDGE TREATMENT OF TYPHOID FEVER.

BY W. BAYARD SHIELDS, M.D.

MEMBER OF THE ARKANSAS STATE MEDICAL SOCIETY AND THE AMERICAN MEDICAL ASSOCIATION.
ST. FRANCIS, ARK.

A good deal of attention has been paid to articles which have appeared at various times in the last few years in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION by Dr. J. E. Woodbridge, of Youngstown, Ohio, one of the trustees of the ASSOCIATION, in regard to his treatment of typhoid fever.

This treatment is according to a method based on the inhibitory influence which antiseptics frequently administered have on the typhoid bacilli in the intestinal canal, checking their activity, hence preventing the rapid and abundant development of toxins, the absorption of which into the system produces the grave nervous troubles so frequently seen in this disease. That the absorption of the toxins formed by the destructive and putrefactive action of the typhoid bacilli is the cause of the nervous symptoms in this disease seems beyond a doubt in my mind, and not, as has been assumed by Liebermeister, to be caused by the high temperature. Strumpell shows after careful investigation, that the height of temperature frequently bears no relation to the amount of nervous derangement, and that in cases of this fever with perhaps high ranges of temperature there are frequently no nervous symptoms. Frantzel has published lately striking cases of this sort. I imagine that these cases are in patients whose nervous centers have greater powers of resistance to toxic influences as we frequently see in other diseases.

The absorption of the result of putrefactive destruction in the intestinal canal also is undoubtedly the cause of the bronchitis. Bacteriologists have of late years proven that the majority of cases of bronchitis (in children especially) are caused by the absorption of the products of intestinal infection, and they almost invariably relieve the bronchial symptoms by small doses of calomel frequently administered which is perhaps our most reliable intestinal antiseptic.

Dr. James Herrick, of Chicago, in a paper read several years ago at a meeting of the AMERICAN MEDICAL ASSOCIATION in regard to his experience in the treatment of a thousand cases of typhoid fever, says that the internal administration of antiseptics prevents the development of nervous symptoms and tympanites by

inhibiting putrefaction and the formation of toxins, which has been my experience in testing the Woodbridge treatment.

From Sept. 15, 1894, to Aug. 1, 1895, we had an endemic of typhoid fever in the town of St. Francis. Nearly all of these cases were of severe type, the morning temperature of some being as high as 104. I treated individually twenty-eight cases, with one death, and that in a man whom I had been called to see on the ninth day of disease, and who strictly against my orders was allowed to eat fried meat and bread. The night following he had a profuse intestinal hemorrhage from which he did not rally. Another case, treated by a physician near by, had died from the effects of intestinal hemorrhage a few days previous. These were the first cases which occurred in this endemic. I used in my cases the Woodbridge treatment modified by sponge baths and rectal injections of a quart of boiled water (cooled) at 10 A.M. and 3 P.M. each day, with thirty drops of carbolic acid in each injection as a deodorant. These cool water injections would reduce temperature and relieve the bowels of effete material. The addition of the acid had been suggested to me some years ago by Dr. Peckham, U. S. Marine Hospital Service, who was then located in Memphis, and had used such injections in typhoid fever with a light mortality.

The last ten cases I treated I also washed out their stomachs, every day for first week of treatment, with cold boiled water which had a most remarkable effect in reducing temperature, and seemingly did not depress them. I introduced the stomach tube with the patient in a recumbent position, anesthetizing their throats with a 5 per cent. solution of cocain, and used a gallon of water at each lavage.

The medical treatment was that of Dr. Woodbridge, using formula number one, two and three, following his directions as near as possible. I believe that the carbonate of guaiacol and small doses of calomel are the most valuable ingredients in this formula.

- R. 1.
- | | |
|-----------------------------|-----------|
| Podophyllin | 1-960 gr. |
| Hydrarg. sub. mur | 1-16 gr. |
| Carb. Guaiacol | 1-16 gr. |
| Menthol | 1-16 gr. |
| Sacch. lactis | q. s. |
- R. 2.
- | | |
|------------------------------|-----------|
| Podophyllin | 1-960 gr. |
| Hydrarg. sub. mur | 1-16 gr. |
| Carbonate Guaiacol | 1-4 gr. |
| Menthol | 1-16 gr. |
| Thymol | 1-16 gr. |
| Sacch. lactis | q. s. |
- R. 3.
- | | |
|--------------------------|---------|
| Carb. Guaiacol | 3 grs. |
| Thymol | 1 gr. |
| Menthol | 1-2 gr. |
| Eucalyptol | 5 m. |

Number 1 was given every fifteen minutes for twenty-four hours, and if in that time the bowels had not acted freely, was continued for twelve hours longer, then No. 2 every half hour for twenty-four hours, then every hour for twenty-four more hours; then No. 3 every three hours. A number of cases seemed to be materially shortened; one case especially with a morning temperature of 103.8, and an evening temperature of 105, reached normal on the morning of the thirteenth day of treatment and the fifteenth day of disease.

The average duration of twenty-three of these cases was fifteen and one-half days. The other cases with

one death did not seem to be materially benefited. One of these cases, to which I was called to see on the twelfth day of the disease, running the regular course of not less than thirty-five days after seeing her, at which time the Woodbridge treatment was instituted. The treatment was left off after twenty days in this case, not seeming to produce any benefit, and the patient treated symptomatically. In all cases pyalism can be prevented by using a tooth powder of potassium chlorate once daily, which destroys the microorganisms around the roots of the teeth which are especially active while the system is loaded with mercury, and is the cause of pyalism. I think the mercury in the prescription is very essential, as it assists in throwing off the effete material. I did not give a single dose of opium or astringent except in one case, and that the case in which I left treatment off after twenty days.

The eliminative action of calomel and rectal injections kept bowels open and prevented diarrhea, the results of the efforts of nature to get rid of the toxins of the disease. They would have under this treatment from four to six actions in the twenty-four hours, which is a thing urgently necessary, according to my judgment, in this disease. Only two had intestinal hemorrhages, one ending in death, and in these cases the rectal injections were left off. Several cases I was called to see which had already exhibited marked cases of tympanites were relieved of the latter by this treatment in a few days. I noticed that especially their nervous symptoms were alleviated by these antiseptics frequently administered, the gastro-intestinal tract being simply flooded. I do not feel so enthusiastic as Dr. Woodbridge does in thinking every case could be saved, but I do think that his treatment, in connection with sponge baths and rectal injections, an improvement over Brandt's one-sided bath, or someone else's exclusively medical treatment, notwithstanding Professor Osler's declaration that no known remedy shortens the disease by one single day.

Not a single dose of the coal-tar derivatives were given. Only the sponge baths and rectal injections of cold water, both of which I think quite necessary, being used to reduce temperature.

Dr. Peckham assured me, that according to his observation, the addition of the carbolic acid to the enema had no deleterious effect, and although I watched it carefully, could see none myself.

I think the stomach lavage a great assistance in the first stage of this disease, but not so essential as the rectal injections. The latter would reduce temperature without the acid, but once in a while a little of the acid would be absorbed, producing free perspiration, though no weakness. My results have not been so good as those of Dr. Woodbridge, perhaps my own fault, not being so familiar with the treatment, but were I to pass through another epidemic, I should certainly rely upon this as my sheet anchor, for seemingly in a number of cases the results were brilliant, although cognizant of the fact that not infrequently a case will start with severe symptoms and subside in a few weeks under symptomatic treatment. I saw in a number of cases of high morning temperature, an amelioration of symptoms under this treatment, and when I would experimentally leave off medicines the symptoms would be aggravated.

Dr. Woodbridge has simply carried to the fullest extent, in my judgment, the treatment advocated by some of the leading men of the profession for a num-

ber of years. The frequency of administration of doses at first does not disturb the patient so much as one would suppose, if so after 10 P.M. I would give a double dose of number one every half hour until morning.

In conclusion I would say that Dr. James Jackson, of Boston, advocated the use of gastric lavage a number of years ago, especially in the first stages of the disease and thought it could be aborted in some cases by its prompt use.

IS HYSTERECTOMY FOR PUERPERAL INFECTION JUSTIFIABLE?

Read by title before the Southern Surgical and Gynecological Association.

BY R. R. KIME, M.D.

PRESIDENT OF ATLANTA OBSTETRICAL SOCIETY; PRESIDENT OF ATLANTA MEDICAL SOCIETY; VICE-PRESIDENT OF THE TRI-STATE MEDICAL SOCIETY OF GEORGIA, ALABAMA AND TENNESSEE; EX-PRESIDENT EXPOSITION HOSPITAL STAFF, ETC.
ATLANTA, GA.

At the present time this is an important question and of interest to the medical profession in general. While asepsis and antisepsis have rendered incalculable service in the prevention of puerperal infection, such cases occur and we are compelled to devise means for their relief.

Before adopting any line of treatment or surgical measure in these cases, it should be established that they are life-saving commensurate with the risks incurred by their use.

Before hysterectomy can be adopted as a justifiable measure in puerperal infection it must be demonstrated that it will save lives that can not be saved by less heroic treatment.

From inquiry of eighteen leading gynecologists and obstetricians, I find five opposed and thirteen in favor of the operation.

Out of fifteen cases operated upon eight have died, making a death-rate of 53 $\frac{1}{3}$ per cent.

In most instances it is said that the operation is done as a last resort in severe cases, and with the oft-repeated remark, "the patient would have died without it." While this may be true, all of us have seen such patients get so low and yet recover that I have lost confidence in such positive prognoses.

The advocates of hysterectomy advise it for disease limited to uterine body, such as septic metritis, multiple abscesses in uterine wall, uterine thrombo-phlebitis, and gangrene of uterus.

Pyosalpinx, ovarian abscesses, etc., are the secondary localized results of puerperal infection, hence operations for such do not come within the scope of this paper.

The fact that a patient recovered from hysterectomy is not conclusive evidence that the operation was justifiable. A uterus filled with putrid material can be removed and patient recover in the great majority of cases, yet the condition does not justify such measures. The same can be said of all cases of putrid infection, for they can be relieved by less heroic measures and without sacrifice of pelvic organs.

In septic infection when *serious constitutional* symptoms develop, the process in *most* cases is no longer local, and can not be removed by hysterectomy, the germs and septic material having extended beyond the uterus, tubes and ovaries into the blood vessels, lymphatics, pelvic cellular tissue, and the general circulation. In a few cases the process may be sufficiently local to justify hysterectomy, but to diagnose

such a condition is a difficult task. None but an expert can do so, and they are frequently mistaken in diagnosis.

Most gynecologists that favor hysterectomy advise to curette and tampon uterus, and if the patient does not improve or grows worse then remove the uterus.

If this is a correct guide as to the indications for hysterectomy, then it is not a question of diagnosis, but failure in a certain line of treatment to give relief that demands the sacrifice of the uterus. In severe cases of septic infection to curette and tampon the uterus, then perform hysterectomy, the death-rate would be so high as to condemn the operation and many lives would be lost that could be saved by less heroic means.

To be more explicit, I will deviate from the title of this paper and enter briefly into the pathology and treatment of puerperal infection.

It is of two general varieties, viz.: 1. Putrid infection or sapremia. 2. Septic infection or septicemia.

The first is a local infection due to decomposition of the uterine contents by putrefactive bacteria only without migration of the bacilli, not contagious, non-progressive by invasion, due to absorption of ptomaines not inoculable.

In sapremia, putrid infection, remove the putrid material from the uterine cavity, irrigate, disinfect, drain, and 99 per cent. of cases will recover. Hysterectomy would relieve these cases, but it would be criminal to sacrifice the generative organs when such cases can be treated more successfully and with fewer deaths by less heroic measures.

The second class is due to germ development, their rapid migration and invasion of new tissue even entering the general circulation; if at first local it soon becomes constitutional, highly infectious, and inoculable from case to case. The contagious principle is destroyed by boiling, putrefaction and germicides.

In the treatment of septic infection we have a more difficult problem to solve.

The septic germs soon extend beyond the endometrium, invading its muscular structures, the lymphatics, the blood vessels, etc., and can not be removed by ordinary surgical measures, and it is very doubtful if hysterectomy could completely remove the infected tissues in severe cases.

In putrid infection the curette and tampon might relieve the patient, but in septic infection I do not believe such treatment is advisable, except it might be within one or two days after labor, where placental tissue has been left in the uterine cavity.

It is drainage and elimination we desire in these cases, not obstruction. What surgeon of repute would tampon an abscess cavity through a very small opening without using a drainage-tube, letting the gauze remain two, three or four days, especially when there is a broken down tissue, débris and septic germs present in abundance.

After delivery nature establishes a process of elimination by a current flowing from the uterine cavity, the uterus and vagina being the main trunks of a sewer; the lymphatics, blood vessels, and uterine sinuses, its tributaries, obstruct the main channel, and what is the result? Who could think of filling the trunk sewer of a city with gauze and expect free drainage, even if done antiseptically after scraping out and flushing it? Yet we are advised to curette the uterus and fill it with gauze, damming up nature's channel of elimination, thus preventing the throwing

off of effete material from the placental site, endometrium and lymphatics—obstructing the egress and retaining the phagocytes laden with germs and toxins, completely annulling phagocytosis, producing the very condition we should endeavor to prevent. Some will say only tampon after a thorough curetting; so much the worse, you have broken down and destroyed nature's barrier, opened up new surfaces for absorption, and favor that absorption by obstructing nature's method of elimination. I regret to say it, but it is my conviction that the curette and tampon indiscriminately used kill more patients than they save in septic infection.

Their indiscriminate usage manufactures cases for hysterectomy. In the treatment of these cases imitate nature as far as possible and establish a current of free drainage.

If any foreign substance is in uterus remove it with the forceps, wounding endometrium as little as possible; irrigate the uterine cavity thoroughly with an antiseptic solution and introduce as large-sized rubber drainage-tube as the os will admit. Repeat irrigations and cleansing of the drainage-tube at least once or twice in twenty-four hours. Do not neglect occasional use of salines and calomel if needed, with systematic use of quinin, strychnin, tonics, and good nourishing diet. Quinin certainly has a specific action in these cases in checking germ development and controlling the chills which accompany these cases. I venture to say that where this line of treatment is properly carried out it will save more lives than the combined use of the curette, tampon, and hysterectomy. While I have in a great measure condemned hysterectomy in puerperal infection, I admit it has a limited field of usefulness in septic metritis, multiple abscesses in the uterine wall, thrombophlebitis, if it were possible for us to be positive in our diagnosis, but if in doubt I prefer drainage.

Unless future operative work gives better results, even this limited justification of hysterectomy may be abandoned.

In the above collection of cases I am satisfied, if the operation be limited strictly to severe cases of *septic infection*, rapidly progressive and not in its secondary results, the death rate would be 80 or 90 per cent. of cases operated upon. Even a death rate of 50 per cent. is sufficient to condemn the operation. The proper use of the drainage-tube will not only save more lives, but the uterus, tubes and ovaries will be preserved for future usefulness and the surgeon's conscience left more at ease.

CÆSAREAN SECTION TWICE IN ONE PERSON.

BY J. W. COAKLEY, M.D.

MT. ETNA, IOWA.

August 3, 1893, I was called to see Mrs. P., aged 30 years, in her fourth pregnancy, there having been previously one abortion. I had performed craniotomy in two preceding labors on account of so great contraction of the pelvis that it was impossible for the child to be delivered, as the conjugate diameter was less than two and one-half inches.

It was difficult to assume the responsibility of the operation owing to opposition to it by elder members of the profession, as indeed it has been one of the most hazardous operations known until within the light of aseptic surgery.

Dr. Harris collected with great industry 153 operations performed by the older methods in the United States, 56 of which, or 37.5 per cent, ended in recovery; under this showing it will be seen that more than one-half of the cases proved fatal.

Baudon, writing in 1873, said, in Paris there had not been one successful case in 80 years, though the operation had been performed on perhaps as many as 50 women. I believe the responsibility for these results to be due to septic infection in the first place, and second, the postponement of the operation until death impended. I believe the surgeon is, in the majority of cases, responsible for the death of the patient when due to sepsis; and further, when the dressing is complete no inexperienced nurse should have anything to do with the case.

However, I decided not to destroy this the fourth child, and the mother consenting to the operation I called as assistants Drs. Sweet and Bryant. I operated on August 4, 1893. On the evening of the third I gave a cathartic and moved the bowels thoroughly, and emptied the bladder prior to the operation; every antiseptic detail was carried out with cleansing and disinfecting the patient's abdominal surface and vagina. In all the steps of the operation the most rigorous precaution was observed. Morphia and belladonna with nux vomica were given to sustain the nerve centers during anesthesia by chloroform.

After the patient was under full anesthesia I made an incision to the peritoneum through the abdominal wall in the median line from four inches above the umbilicus to within two inches of the pubis. The peritoneum was opened on a grooved director with scissors, and the uterus lifted bodily outside the abdominal cavity and wrapped in hot antiseptic towels. The upper part of the wound was temporarily closed with silver sutures to restrain the abdominal contents; a broad, flat sponge was wrung out of hot bichlorid solution and placed posterior to the uterus over the abdominal incision for further safety; a rubber ligature was passed around the neck of the uterus to prevent hemorrhage. An incision four inches long into the uterus and penetrating to the sack was then made to prevent the escape of the amniotic fluid into the cavity of the abdomen. The child was removed from its lair with membranes intact, which were then ruptured and placenta removed: no vessels of any size were severed. The rubber ligature was taken off, uterus washed out with disinfectant fluid and the uterine incision powdered with iodoform. The edges of the wound of the uterus were brought together with deep interrupted sutures of catgut about one-half inch apart, made with a curved needle one-quarter inch from the edge of the incision through the muscular tissue of the uterus, but not including the mucous membrane. Sutures were tied firmly, but not so tight as to strangle the enclosed tissue. For the purpose of approximating still more the edges of the incision, a set of superficial stitches of silkworm gut were inserted between the other stitches about one-quarter the thickness of the uterine walls.

Careful inspection was made of the abdominal cavity, and we concluded not to irrigate because no blood or other septic material was found within the abdomen. The peritoneum was united with continuous sutures of silkworm gut: the abdominal walls were next coaptated with interrupted sutures of silk, the whole wound being dressed with iodoform gauze and absorbent cotton.

Within an hour the mother conversed joyously over a living babe, and myself and assistants were no less pleased than the brave mother. The next day her temperature was normal and but for slight vomiting from the anesthetic the patient was tranquil. On the third day after the operation, she had a little fever for the first, owing to secretion of milk; the temperature of 100 lasted one day. On the fourth day, temperature normal, and she furnished milk for infant, and the mother was anxious for food to appease her own appetite. On the fifth day bowels moved and temperature normal; on the same day dressings were changed, wound completely healed by first intention. On the tenth day of the operation no untoward symptoms. On the twenty-first day of the operation patient walked through the house and felt as well as ever, excepting muscular debility.

During a subsequent pregnancy in the same patient the husband urged a miscarriage to be performed, which I refused absolutely, not feeling justified in destroying a child which the mother desired to save. Under the present advancement in antiseptic surgery, when we have statistics to show that the fatality to the mother in craniotomy is 47 per cent., my answer was in the negative.

I was again called to see this same woman in labor at full term pregnancy on July 27, 1895, and gave morphia to control the pains and prepare her until next day for the second operation. The room had been washed in bichlorid solution, and sulphur fumigations had been used and thorough sprinkling with carbolic acid solution at the time of the operation, and the patient had attended to antiseptic baths and vaginal douches, and her system had been fortified by tonics. I was assisted in the operation by Drs. Sweet, Salts and Davis, with my wife as special nurse. The patient was anesthetized at 11 A.M., having first taken nux vomica and morphia. Only about 1 ounce of Squibb's chloroform was inhaled during the entire operation, which lasted fifty minutes. This time the case was somewhat complicated by reason of the placenta being attached near and over the os uteri, as in a case of placenta previa. I cut through the former cicatrix and found the wall of the uterus to be extremely thin. The rubber ligature was tightened, the child turned, to save time membranes were ruptured, child removed and turned over to Dr. Salts. Placenta quickly removed with all adherent portions of the decidua carefully separated. Ligature was loosened and uterus washed out with a disinfectant fluid through vagina. Hypodermic injections of ergot and strychnia were given. The uterine cavity and edges of wound were powdered with iodoform, after first being sponged nearly dry, and sutures and all subsequent details finished as above related in the first operation. The patient did not lose more than an ounce of blood at most; neither had I to ligate nor use torsion on any vessels. Her temperature never rose but one degree above normal after this the second operation, and that on the third day at the appearance of the milk; after that no rise of temperature and she furnished plenty of food for the child. On the fourth day the dressing was changed and found no irritation, wound completely healed by first intention. We irrigated the uterus twice a day as in the first operation for the first five days afterward, with a reflux catheter and a bichlorid solution, and the next five days once a day with warm solution of boracic acid. Finding no discharges after this the tenth day, we abandoned all further uterine

interference, believing that organ to be in a healthy condition which I think was owing to the antiseptic injections during and after the operation especially. She rode out five miles on the twenty-first day after the operation.

My judgment in the matter is, the Cæsarean operation is a superior one and should be generally performed when the child can not be born alive in any other way. The girl, two years old, after the first operation, and the boy after the second one, with the delighted mother, live and thus add a further triumph to the success of antiseptic abdominal surgery.

THE VALUE OF DIFFERENTIAL DIAGNOSIS IN DENTISTRY.

Read in the Section on Dental and Oral Surgery, at the Forty-sixth Annual Meeting of the American Medical Association, at Baltimore, Md., May 7-10, 1895.

BY V. A. LATHAM, M.D.

CHICAGO.

The subject of diagnosis is one of much importance to a practitioner, and the man who can diagnose rapidly and correctly is usually successful in his profession. In medical works great importance is laid on diagnosis even to such a degree that special works are written on the subject. Who does not remember the differential tables in nervous, respiratory and cardiac diseases, and the dread they inspired at examinations? Without their aid we are not able to diagnose our cases, and hence the urgency of requiring students to learn them. I have constantly been surprised at the difficulties which students encounter in dental surgery and pathology. Even a well-read student finds it hard to bring his knowledge to bear promptly and efficiently upon the patient before him. The recognition of the several symptoms which the student has learned from lectures or reading can be best directed by the teacher at the side of the operating chair, just as it is at the bedside in medicine; but in his absence it is not always easy for the student to get a clue to the nature of the case before him. Every member of the dental profession can recall the days of his service in the operating room, and remember his difficulty in procuring help from the professor or his assistant, for as a rule, the corps of instructors in our colleges, medical and dental, is much too small to allow more than a passing glance or word to any inquiring student, and he does the best he can. Whether this is a wise plan or not is a subject for discussion, for several reasons. First and foremost, the student is incapable, in the majority of cases, of understanding the treatment of his earlier cases. Again, the patient, even a charity case, under these conditions is entitled to good judgment in his diagnosis, though willing to submit to the student operator; his position demands the supervision of a chief, not only for the care and result of the operation, but for the welfare and regard of the institution in which the operation was held. It is not always a patient's fault that he is a public case, and indeed we, as a class of students, graduates or undergraduates, must remember it is through their misfortune we obtain our practical experience, and so ought to give every care and attention to do the best we can for the "subjects of the clinics." The larger the clinics, the more benefit we may derive from them. The larger the corps of capable demonstrators under the guidance of an experienced diagnostician as "chief," the more practical and successful professional men and women we become.

It is evident that before any one can successfully treat a disease, he must be acquainted with its nature and the symptoms it produces. For instance, before prescribing for a patient suffering from pain in the head, he must ascertain from what that pain arises. It may result from a carious tooth, when treatment or extraction will give relief; or from periostitis, when potassium iodid will be beneficial; or from constipation, for which only a purgative is required; or again, it may be symptomatic of an incurable disease of the brain, which might be aggravated by many of the remedies well fitted for the cure of a less formidable disorder.

Diagnosis is the science which teaches us thus to distinguish one disease from another, and to trace symptoms to the causes from which they spring. Now diagnosis is valuable not only for treatment, but it enables you to form an accurate opinion as to the future course of a disease. For example, two persons may complain of palpitation of the heart; in the one you may be able to prove that the organ is healthy in its structure, but unduly excited by disordered digestion; in the other, you may find it affected with an incurable disease that may at any moment terminate your patient's life. It seems a curious fact that works on dental surgery are so very imperfect and rambling on the subject of diagnosis. I doubt if any branch of medicine is so poor in this respect. And although the dental section may be given grace on account of its late arrival, still it is a matter of regret that our text-books should be so much behind, and research so slow in progress, that is slow in availing itself of so many new facts introduced from science generally. What is the reason? I am afraid it lies in five sources:

1. The hurry to obtain a diploma.
2. The study of *only just* what seems absolutely necessary in the practice of dentistry, and a corresponding inability to apply general principles.
3. The fear of encroaching on general medicine.
4. Insufficient preliminary *education*.
5. Lack of a thorough knowledge of the *normal conditions*; and a habit of relying too much upon one mode of treatment.

Diseases are distinguished from each other by such alterations in the organs themselves or in their secretions as can be ascertained by the senses of the observer (physical signs); or by changes in the functions of the parts affected (symptoms). The physical signs are least liable to misconception, inasmuch as we are independent of any suggestion on the part of the patient. Thus we see a carious tooth or an exposed pulp, or a swelling we know that there must be some abnormal condition of the part. Physical signs can not be exclusively relied upon for the formation of a diagnosis; the symptoms and history of the case must also be taken into consideration. It is generally difficult for a student to guide a patient's account of his complaint in such a way as to derive the necessary information from it. Most persons ramble in describing symptoms, and insist in many cases on giving their own or other person's opinions as to the nature of their disease, instead of confining themselves to a narration of facts. The only way to overcome this is by conducting your examination in a systematic manner, and by having a definite aim in every question you ask. Students are apt to suppose that some particular sign or symptom is sufficient to indicate each disease. Unfortunately, this is not the

case. On the contrary, we can rarely diagnose any morbid condition without taking into consideration a number of symptoms; indeed we are often forced to determine the nature of a malady by proving what it is *not* rather than what it is, diagnosis by exclusion.

The subject of "taking cases" ought to be insisted upon in all medical and dental hospitals and colleges, and all students should be required to examine cases and to write out their histories in their operating or clinic service, the reports to be read and criticized before the class by the professors of the several subjects. To know which points are the important ones is anything but easy, and can only be acquired by experience, and through sound teaching. How many valuable cases become wholly worthless from the reason of bad or incomplete histories is only known to those in the profession who try to do legitimate and scientific study. Hospital internes are generally poor history takers because they are badly trained, and are often overwhelmed with work, the number of patients allotted to each interne being too great to permit thorough, painstaking work. This is often injustice to the patients, and always so the interne; for the value of his appointment lies in the opportunity for the close study of his cases, under a staff of skilled consultants, from whom he can inquire concerning obscure points in signs and symptoms, and whose discussions and remarks upon treatment and results serve to impress the points indelibly upon his memory. For this training he gives his time and strength, and certainly has a right to all the privileges of his position; he ought not to be worked like a machine! It is not the number of gold fillings inserted in a day, but the nature of the caries, its etiology, treatment and results we are after. What good is it to teach a student to insert a gold filling with a perfect adaptation and contour if he does not recognize the variety of decay, the resistance and pathologic conditions offered by the histologic elements, the condition of the gums, the development and articulation of the maxillæ and teeth, the state of the secretions of the stomach and oral cavity, as well as the general condition of the patient? It is worse than useless to expect good results, except by chance, without accurate knowledge on these vital points. For we must remember that the general health will permit only of temporary measures in such constitutional states as diabetes, locomotor ataxia, pregnancy and in convalescence from the acute fevers.

The most difficult problems, perhaps, we have to diagnose in dental pathology are the neurologic. Dental irritation is one of the commonest and most powerful causes of reflex nervous disturbances. We all know of many cases treated by the medical profession for months which might have been relieved by attention to the teeth. Understand, I do not mean to omit the medical treatment of such diseases as syphilis, malaria, neoplasms, and so forth. The terminations of the fifth nerve, namely the pulps, seldom allow increased circulation because of the resistant walls surrounding them, by which the entire pressure is reflected back to the central nervous system and to all peripheral nerves. Even when the sufferer indicates a special tooth, we may find the trouble in the other jaw and on the opposite side. It may not be amiss to consider here some varieties of pain and their indications. Two sources of dental pain are: 1, the nerves of the tooth-pulp; the dentinal

fibrils and the contents of the inter-globular spaces of dentine; 2, the alveolo-dental periosteum.

Pain arising from the pulp and from the dentinal fibrils is always the same in character, but may vary in degree. The pulp and protoplasmic elements of a tooth may set up a localized pain; but usually the pain arising from these structures is now localized, being felt at a distance. Periosteal disease, on the contrary, invariably causes local pain, and never pain at a distance, or only such as is quite insignificant when compared to local pain. Thus, true neuralgia never arises from uncomplicated alveolo-dental periostitis. Neuralgia, therefore, never arises uncomplicated from a dead tooth. This, as proven by experience, helps us to arrive at a correct diagnosis of the cause of one variety of dental pain. Often obstinate cases of obscure neuralgic pain can be cured by curing alveolo-dental periostitis of a dead tooth. This may be explained by assuming that the periostitis is complicated with some irritation or inflammation of a neighboring pulp; which irritation or inflammation may be passed on from the inflamed periosteum to the pulps in its proximity by continuity of tissue. When this is the case, the pulp is attacked from the proximal end, the inflammation following the apical foramina nerve and vessels. Where alveolo-dental periostitis occurs in live teeth, there is almost always some irritation or inflammation of the pulp, which may be secondary or otherwise. The following are modes of diagnosing causes of pain, in or from the teeth.

1. Explore with the mirror and a sharp pointed probe, find the cavities, then test for living or dead pulps. If the deep cavities are sensitive or the nerves exposed, here is the probable cause of the pain. These are our easy, straightforward cases. If, however, no pulp canals are open, then we must

2. Test by percussion and thermal changes. If the pulp is found unduly sensitive hyperemia and irritation are indicated; if insensitive to thermal changes, partial or complete necrosis may be diagnosed. (The heat test must be applied for some time, so the tooth feels hot to the finger, before necrosis can be regarded as proven.) This is not always true, though it is fair to conclude that hypersensitiveness to thermal changes indicates the tooth as a probable cause of neuralgia; while diminished sensibility is as often a sign of partial or complete necrosis. If we are still doubtful

3. Drilling is justifiable, for if the pulp be alive, though much receded by calcification, pain will generally be felt by the cutting of the dentinal fibrils before the pulp is reached. Carefully distinguish, however, between pain caused by the pressure of the instrument in cases where alveolo-dental periostitis is present, and that due to hyperemic pulp. Any branches of the fifth nerve in the head, face or teeth, or even more remote nerves, as the superficial cervical or even the brachial nerves, may be the seat of neuralgic pain arising from any tooth on that side. The pain, however, never crosses the vertical median line, often the faulty teeth being unsuspected by the patient. Reflex neuralgia from such a tooth may occur anywhere, but usually its favorite location is where the nerves emerge from foramina and where they anastomose. There are also certain preferred sites for certain teeth. For example, pain in the ear and pain shooting down the shoulder and into the arm, if dental in origin, is almost certain to arise from an inferior tooth. Pain, supra- and infra-orbital, almost

always arises from a superior tooth. Temporal pain, pain in front of tragus over auriculo-temporal nerve or parietal pain, "parietal focal spot," usually arises from a tooth in either mandible. Pain felt in one tooth is often due to a companion tooth in other mandible. Pain widely diffused in character, *i.e.*, shooting along many branches of the fifth nerve at one and the same time is usually from a tooth far back in the mouth, third molar. Pain of a live pulp is not continuous but capricious, lasting a short time and suddenly disappearing, periodic in appearance, frequently benefited by medicines, as salicylate of soda, quinin and other tonics or stimulants. In both these particulars neuralgia arising from the pulp agrees with neuralgia arising from unknown or constitutional causes (idiopathic neuralgia). This similarity of behavior has often led to a false diagnosis of the etiology of neuralgia on the part of physicians and dentists. The pathologic pulp which causes neuralgia of the usual capricious character is often in a state of chronic inflammation; acute pulpitis seldom reaching the dental surgeon in the early stage, the pulp soon dies. In pulpitis, cold alone is acceptable to the patient for giving relief, periosteal symptoms being nearly always present. Nerve exhaustion means increased nervous irritability. Anemia of young subjects, especially, causes severe neuralgia to arise from such slight causes as exposure of dentine at the necks of the teeth, through irritation of the dentinal fibrils and their canalicular terminations.

With regard to etiology of dental periostitis and pulpitis, the diplococcus pneumoniae may be regarded as a factor, usually accompanied by the staphylococcus pyogenes aureus and albus. Long continued pulpitis may cause inflammation of the antrum just as well as a severe catarrhal inflammation can do so. Non-eruption of the teeth, which is very hard to diagnose in the early stages, can also cause a purulent condition of the antrum, and may give frequent and persistent neuralgia, as well as trismus from irritation of the inferior dental nerve.

Causes of neuralgic pains are: 1, sensitive dentine; 2, fibroid pulps; 3, crowding; 4, necrosis of pulp in a confined space; 5, exostosis; 6, alveolar periostitis; 7, filling over exposed pulp; 8, malpresentation of third molar; 9, rheumatic and gouty diathesis; 10, anemic and chlorotic states; 11, serous calculus on roots; 12, malaria; 13, pulp nodules; 14, sympathy; 15, recession and absorption of gum and alveolus; 16, pressure of gases in the pulp chamber; 17, traumatism.

The most pernicious form of neuralgia is that which is due to septic influences occurring after some traumatic injury, in which paresis or paralysis of the nerve effected sometimes follows.

Differential Diagnosis between Antral Abscess and Ozena. Points in favor of the former are: 1, the presence of pulpless teeth; 2, a shortening of the face from the oral cavity to the orbit; 3, accumulation and sudden reaccumulation of pus, showing at the hiatus, in middle meatus, half an inch from anterior extremity of inferior turbinate bone; 4, discharge of pus increased on putting patient in horizontal position, especially on the sound side; 5, relative darkness over the diseased maxilla when the bones of the face are illuminated; 6, puncture through nose and aspiration of fluid; 7, the presence of carious teeth, especially roots, in upper mandible. Bulging of the cheek and deformity of the jaw are not always present. Ozena is recognized by: 1, characteristic fetid discharge;

2, olfactory anesthesia; 3, detection of denuded necrosed bone in nares; 4, presence of crusts of dried secretions and ulcers, especially in naso-pharynx; 5, the teeth may be normal; 6, diathesis (syphilitic or strumous).

The following appended tables may be useful:

Sensitive Dentine.

When the examination over a considerable part of the cavity walls does not respond to simple pressure. Pain is not persistent.

Hyperemia of the Pulp.

Pain of boring character; tooth highly sensitive to hot and cold temperatures, and painful in mastication and on pressure. Hard to distinguish from exposed dentine. Absence of throbbing pain (pathognomonic of pulpitis); serious neuralgia may be a symptom.

Chronic Pulpitis.

Pain less severe than in the acute form, not very intense nor long in duration when present. Comes on at irregular intervals—often vague neuralgic pains. Sudden changes of temperature, or applications of irritants will produce a paroxysm of pain, lasting from a few minutes to hours. Pulp shows inflammation limited to exposed spot, the rest pale and healthy.

It is often difficult to distinguish pulpitis from hyperemia. In hyperemia the throbbing character of the pain is not so well marked and the pulp usually not exposed. Pulpitis must also be distinguished from periostitis; the differential points being as follows:

Pulpitis.

Pain—sharp, lancinating or throbbing, intermittent and reflected within the tooth.

Thermal changes cause pain.

Pressure or percussion on tooth gives no pain at first.

Slight pressure on a piece of wool in cavity generally gives acute pain.

With pulpitis we may have pericementitis by continuity.

If the Pulp is Sensitive.

When the examination is made near the pulp, it responds to pressure.

Pulpitis.

Pain of a boring character rapidly increasing, assuming a throbbing form, extending from the diseased tooth to the neighboring teeth and to the side of the face, the tooth forming the center of its intensity. The larger and younger the pulp the greater the pain. In time the pain subsides, to return though on the slightest provocation, or the horizontal position being resumed. Pulp injected with blood throughout, the the exposed part deeper in color.

Necrosis of Pulp.

Pain becomes changed to a dull heavy ache with a feeling of tension. Tooth feels too long, raised in alveolus by the pericementitis and periostitis, and loosened; may have some swelling at the side, on the gum or at the root; a change of color can be seen by strong light, the dead tooth having a dark line in the pulp region.

Periodontitis.

Pain, dull, heavy and constant, and without the tooth.

Thermal changes do not cause pain.

Pressure or percussion on tooth gives pain from the first.

Slight pressure does not give pain except through pressure transmitted to the periosteum.

Tooth loosens and elongates.

A student may be well versed in the sciences of his profession, and yet unable to diagnose the simplest case of disease presented in actual practice, simply because the knowledge has not become his own in sufficient degree to enable him to comprehend appearances. Diagnosis, to be useful must not only be clear and satisfactory to our own minds, but made so plain to those in charge of the case as to render them alive to the real necessities present, thus securing that coöperation without which treatment will be ineffectual, if not actually a damage to those we essay to

benefit. No diagnostician who is conscientious as well as competent will set up his own opinion as the standard, but will always rely upon the perception of those to whom he wishes to make the diagnosis plain, and in this very idea is the safety: for the recapitulation of the case may reveal points previously unnoticed, so giving certainty and confidence to the patient and himself. To become a good diagnostician, it is imperative to understand principles and laws, in preference to formularies and modes; and to comprehend these, one's powers must not only be good, but kept in constant use, thus insuring the best and latest methods, reading and experience.

808 Morse Avenue.

FADS AND "ADS."

Read before the Southeastern Missouri Medical Association.

BY W. P. HOWLE, M.D.

ORAN, MO.

Who is there, these days, without a "fad"? Every man has at least one, some have many, whether they know it or not. Doctors are especially prone to this trouble. One doctor's fad is writing and reading articles for his medical society, another doctor's fad is to object to everything written or said. I know a doctor whose fad is fine horses. He thinks a doctor without a fine horse is no doctor at all. I know another doctor whose fad is a cleanly office, and he is disgusted with any doctor who does not keep his office clean. I know another doctor whose fad is to have an office in such a condition that all are disgusted who enter it. Iodoform or carbolic acid is the first thing you smell, and dirt is found in and upon everything he handles. If asked why he indulges this fad, he claims it is because he is so enormously *busy* that he has no time to clean up. Keeping a dirty office is not his only fad. His principal fad is to impress upon every one that he is a wonderfully busy doctor. I have a neighbor (and this reminds me that some people's fad is talking about their neighbors, but I am not talking about mine), but as I said before I have a neighbor who invariably tells me every time he sees me how much work (practice) he has done. I have another neighbor whose fad and "ad." is loud talking. He is always known when he is in town. He talks in a loud voice to his friends across the street, saying: "How are you?" "How are you to-day?" "How are your folks?" "Why, hello, Jim! I'll see you directly. I am *busy* now." Fads and ads. go together. Each of us have more or less egotism. We may be modest in the main, but the doctor who has no weak point is an exception. So much for fads and ads. which do little harm and are to some extent excusable. But the object of this paper is to call attention to a fad that is doing the profession, and through it the laity, more harm than all other fads combined. I refer to our daily use of *proprietary compounds*. This is an everyday fad with the majority of us. Some of us indulge this fad in one way, some in another. We prescribe these compounds for several apparently good reasons: They are generally palatable; some of them are quite reliable; it saves time and trouble in prescribing. For instance, I believe that quinin and iron are indicated in a certain case, I prescribe someone's elixir of quinin and iron already made. The dose and proportion may not be exactly what I want, but through laziness or carelessness I fall into the trap for me. These compounds, as a rule, are labeled

and indication given, and some have an extra wrapper, on which are reports of cases treated and results. These we do not order, but the smooth manufacturer saw the point. He knew if the doctor prescribed the compound the curiosity of the patient would lead him to read all about it, after which the patient gets a fad of his own, and that fad consists in buying these compounds without consulting the doctor. So you see there is an "ad." and fad in this connection that makes it interesting. Look at such remedies as — hypophosphites, maltin, bromidia, listerin, — emulsion and the host of other proprietary medicines. They are being bought at *exorbitant prices* because we recommend them. See the unfairness, if not rascality, that is hidden over our signatures. When you write a prescription and mention calomel as an ingredient do you call attention to its many virtues in other complaints beside the one you prescribe for? In prescribing quinin do you give it such a "send off" as do the manufacturers of — give their products? If you do not, and do not think it right to do so, why do you prescribe these compounds? You know that they are being "puffed" by their makers to a greater extent than many patent nostrums, and we know comparatively as little about some of them as we do of — sarsaparilla. One of my fads and ads. is not to prescribe any remedy with an almanac attachment. As a rule, I make my own prescriptions. Once in a while I prescribe acetanilid; I don't know how it is made, nor do I know exactly how calomel and quinin are made. I know that quinin is made of Peruvian bark, that calomel is made of mercury and that acetanilid is a coal-tar product; but none of these have an almanac attachment. They are simply labeled and the patient can not tell from that label what they are made of or for. And I get in another of my fads by *telling* him (for his money's sake). I am tired of assisting ready-remedy-makers in swindling the profession and, through it, their patrons. This article is written to draw out the opinions of the Society on this subject. I brought the matter up at our last meeting and no one would back me in condemning this fad; but to-day I think I have backers who will point out our error in this matter in ways that I have not mentioned. I appeal to you again and ask each of you to express himself fully. I believe we are all guilty. If we are and can see that we are doing wrong, why shall we not stop? We save time and trouble at the expense of study and duty. It is a sad comment, but some of us are actually too lazy to make out a prescription of our own, and in its stead we write the name of somebody's compound, labeled with directions not only for the complaint we are treating, but for divers others. We read in our journals that — is a specific for la grippe. We take the fellow's word for it and prescribe it. This is a fine way to learn and practice medicine, a *nice* way to study our cases and to learn what is the real lesion in la grippe. La grippe, like malaria, assumes many phases, but it is evident the routine prescription of any one remedy is wrong. Let us study medicine and pharmacy for ourselves. Let us make out our own prescriptions. In fact, let us do our duty as physicians and cease patronizing ready-remedy-makers. We can never restore medicine to its proper sphere by connivance with drug manufacturers. We ought to be teachers of pharmacy instead of its dupes. The proprietary vendor, taking advantage of our laziness and credulity, tells us that he can make our work easy.

light and pleasant; that he has a remedy, a certain noted physician's prescription, which is giving grand results; it is composed of this, that and the other, and is superior to anything known for prevalent diseases. We now have nothing to do but prescribe it and the work is done. The pharmacists have come to our relief. They have analyzed diseases for us, found out the remedy; *they know it all!* We fall into the trap; we cease to investigate; we step down and out while the pharmacist takes our place. We can play *granny and nurse*, but the proprietary man does all the rest. Twenty years from now, if the fad is not "sat down on," the medical student will have to go to the drug manufacturer's establishment for medical knowledge; there will be no colleges. The proprietary man is trying to usurp our place, but is unwilling to teach what he *pretends* to know. You ask him how he makes his product. He will give you a formula, but at the same time tell you he has a *secret* process of *combination*. The true physician has always been and is still willing to publish any and all he knows, but the proprietary man says: "Oh, no! I can not tell you *how* I make my compound. I am making money while you, my dupe, are growing poor. I, with my stolen knowledge, am growing rich, and you are silly and lazy enough to help me." Do you not think it time to call a halt? I do; and I move that this Society refuse hereafter to give any man's compound, who refuses to tell of *what* and *how* it is made.

ANASTOMOSIS OF DUODENUM.

BY C. P. THOMAS, M.D.

EVERETT, WASH.

The patient, J. G. W., was brought to the Everett Hospital Feb. 13, 1896, shot in the abdomen, at close range, with a .38 caliber revolver, ball entering about three inches above and one inch to the left of the umbilicus, and lodged in the back. The abdomen was opened an hour after the injury was received, by a four-inch longitudinal incision at the bullet wound. The cavity was filled with blood; the patient in extreme shock and pulseless. A large hole in the mesentery, which was bleeding profusely, was closed with catgut. The duodenum had two small holes in it about six inches from the stomach, which were closed with fine silk by the Lembert suture. Another perforation was found about ten inches from the stomach which nearly severed the gut and tore the mesentery at the same place. This portion of the gut was resected and end-to-end anastomosis made with the Murphy button. No other perforations could be found. There had been but little escape of the intestinal contents before the operation, owing to their having been empty, and none since. The peritoneal cavity was closed with glass drainage without much irrigation or sponging, owing to the extreme condition of shock which existed. Considerable difficulty was experienced in bringing the ends of the gut within the bowls of the button, owing to the thickness of the gut and to the purse-string sutures having been placed too far from the ends of the gut, and in order to be sure that the serous surfaces were in perfect contact, a continuous silk suture was placed around the entire line of union. The time required for the operation was forty-five minutes. The drainage was removed the fourth day and liquid diet begun the sixth day. Half of the button was passed

the tenth and the other half the thirteenth day. It was found that the secretion of the stomach had destroyed the catches on the springs, which allowed the button to separate. Patient's recovery has been uneventful; he remained in the hospital but four weeks. The button used was one made from a cut which appeared in the *Medical Record* in 1893. It differed but little from the genuine Murphy button which I now have and will use in the future. Preparations had just been made for an operation for appendicitis on another patient, when he was brought in, thus no time was lost in beginning.

The points of special interest are that the anastomosis was done in the duodenum and that the button came away in two pieces.

A FEW NOTES ON EPILEPSY.

BY L. PIERCE CLARK, M.D.

ASSISTANT PHYSICIAN TO CRAIG COLONY FOR EPILEPTICS.
SONYEA, N. Y.

The peculiar ideas that epileptics entertain about their attacks are well illustrated by some of their remarks in describing their seizures. Two or three characterized their fits as "dreamy spells." These were minor attacks in which consciousness was not completely lost, but there was confusion of ideas and a paralysis of will over many of the voluntary movements of the body. These have been designated as psychic attacks by some writers, but by others they are still classed with petit mal. The latter class of diagnosticians regard the subdivision, psychic, as an unnecessary refinement in classification and one not fully justifiable clinically.

One patient has designated his aura in a dramatic manner by saying: "First red, white and blue, followed by a sensation of falling down, down for a long distance; then darkness." During the attenuation of consciousness, the brain has time to record many sensory phenomena. As the elements of consciousness begin one by one to die out, they disturb the time and space relation to a remarkable extent, as on careful inquiry this patient did not remember in a single instance of striking the ground or floor.

Another patient describes the beginning of his attacks in a very hopeless manner. He is attacked by great mental depression in which he is "suddenly stunned by an indescribable sorrow;" this in turn is followed by a "feeling of extreme physical languor, then unconsciousness."

The description of the aura as a vapor, of the ancient Greek designation, has a counterpart in the case of V. S., who says: "There is a kind of wind or vapor which fills my head full to bursting before I get dizzy at all." The wind or vapor idea is established firmly in his mind as a part of his epilepsy, because he is periodically troubled with flatulence and sometimes these periods are concomitant with his seizures.

One patient, who has an epileptic sister, seems to have been thoroughly tinetured with the contagious and infectious idea so prevalent among us at present. She firmly believes that her sister contracted epilepsy from her because they occupied the same bed at night. She carries the idea still further and manifests a great dislike in being obliged to bathe at the same lavatory with those who have a worse form of the disease than she, lest she should contract the severer form. After hearing the patient's description of her sister's seizures, the idea of contagion does not seem so prepos-

terous or wrong, as they partake more of the nature of hysteria than of true epilepsy. They are of such a character that it sometimes takes "three or four men to hold her lest she does injury to herself or others." She is quite prone "to tear her hair" and inflict other bodily injuries upon herself. The symptoms in this case seem to point very strongly to hysteria instead of to epilepsy. Hysteria might easily make its appearance under such circumstances, especially when a member of the family, living with the epileptic, was "nervous and sensitive" and proved an easy subject for suggestion by being constantly associated with a living example. We see an analogy to this in the cases cited by Mercer, Esquirol and others, in which it seemed that other sisters and brothers became insane through association with members of the family who were suffering from insanity previously, this being induced through the influence of suggestion upon a weak and unstable nervous organization.

Although such ideas as have been above recorded are prevalent among epileptics, yet however awful and severe they may appear to them, it does not preclude hope of relief from their severe malady, but makes them even more hopeful than the phthisic patient.

SHOWING ALSO BY THIS METHOD THE PRESENT AND
FUTURE POSSIBILITIES OF TAKING AND RE-PRODUC-
ING CERTAIN ANIMATED PHYSIOLOGIC MOVE-
MENTS AS THE LARYNX, HEART, INTES-
TINES, ETC., AND CERTAIN DISEASES
HAVING VISIBLE SYMPTOMS, ETC.
WITH A HISTORIC REVIEW
OF FIFTY YEARS OF
PHOTOGRAPHY.

Read before the French Academy of Medicine, Paris, February, 1895, and
in the Section on Physiology and Dietetics, at the Forty-sixth
Annual Meeting of the American Medical Association,
at Baltimore, Md., May 7-10, 1895.

BY J. MOUNT BLEYER, M.D., F.R.A.M.S.

Fellow of the Royal Academy of Medicine and Surgery, Naples, Italy;
Corresponding Member to the Mexican Academy of Medicine; Cor-
responding Member Société D'Electro-thérapie, France; Mem-
ber Electrical Association of New York; Member American
Medical Association; Member of the French Laryn-
gological Society, Paris, France.

NEW YORK.

(Concluded from page 677.)

Then followed some experiments with drums, over which sheets of sensitized celluloid film were drawn, the edges being pressed into a narrow slot in the surface, similar in construction to the old tin-foil phonograph. A starting and stopping device very similar to the one now in use was also applied. The pictures were then taken spirally to the number of two hundred or so, but were limited in size, owing to the rotundity of surface, which brought only the center of the picture into focus. The sheet of celluloid was then developed, fixed, etc., and placed upon a transparent drum, bristling at the outer edge with brass pins. When the drum was rapidly turned, these came in contact with the primary current of an induction coil, and each image was lighted up in the same manner as described in the previous disk experiment, with this difference only, that the inside of the drum was illuminated.

Edison and Dickson made the next step by adopt-

ing a highly sensitized strip of celluloid half an inch wide; but this proving unsatisfactory, owing to inadequate size, one-inch pictures were substituted on a band one and one-half inches wide, the additional width being required for the perforations on the outer edge. These perforations occur at close and regular intervals, in order to enable the teeth of the locking device to hold the film steady for nine-tenths of the forty-sixth part of a second, when a shutter opens rapidly and admits a beam of light, causing an image or phase in the movement of the subject. The film is then jerked forward in the remaining one-tenth of the forty-sixth part of a second, and held at rest while the shutter has again made its round, admitting another circle of light, and so on until forty-six impressions are taken a second, or 2,760 a minute. This speed yields 165,600 pictures in an hour, an amount amply sufficient for an evening's entertainment, when unreel before the eye. By connecting the two ends of the strip, and thus forming a continuous band, the pictures can be indefinitely multiplied.

For this system the advantage is claimed by them over a continuous band, and of a slatted shutter forging widely ahead of the film, would be this, that in that case only the fractional degree of light comprised in the 1-2720 part of a second is allowed to penetrate to the film at the complete sacrifice of all detail, whereas, in the present system of stopping and starting, each picture gets one-hundredth part of a second's exposure, with a lens but slightly stopped down; time amply sufficient, as any photographer knows, for the attainment of excellent detail even in an ordinary good light. It must be understood that only one camera is used for taking these strips, and not a battery of cameras, as in Mr. Maybridge's photograph of "The Horse in Motion."

The next step they take, after making the negative band, is to form a positive or finished series of reproductions from the negative, which is passed through a machine for the purpose, in conjunction with a blank strip of film, which after development and general treatment, is replaced in the kinetoscope or phonokinetoscope, as the case may be. When a phonograph record has been taken simultaneously with such a strip, the two are started together by the use of a simple but effective device, and kept so all through, the phonographic record being in perfect accord with the strip. In this conjunction, the tiny holes with which the edge of the celluloid film is perforated, correspond exactly with the phonographic records, and the several devices of the camera, such as the shifting of the film and the operations of the shutter, are so regulated as to keep pace with the indentations made by the stylus upon the phonographic wax cylinder, one motor serving as a source of common energy to camera and phonograph, when they are electrically and mechanically linked together. The establishment of harmonious relations between kinetoscope and phonograph was a harrowing task, and would have broken the spirit of inventors less inured to hardship and discouragement than Edison's veterans. The experiments have borne legitimate fruit, and the most scrupulous nicety of adjustment has been achieved, with the resultant effects of realistic life, audibly and visually expressed.

The process of "taking" is variously performed: by an artificial light in the photographic room, or by daylight under the improved conditions of the new thea-

ter specially erected. This building is known as the kinetographic theater. Entering, we are confronted by a system of lights and shades so sharply differentiated as to pain the eye. Later we find that the contrasts are effected by the total exclusion of light from the lower end of the hall, heightened by draperies of impenetrable black, against which stands out in sharp relief the central stage, on which are placed the kinetographic subjects, bathed in the full power of the color rays, pouring down from the movable roof. This distribution of light and shade is productive of the happiest effects in the films, as the different figures are thrown into the broadest relief against the black background, and a distinctness of outline is achieved that would be impossible under ordinary conditions. This theater in shape is irregularly oblong, rising abruptly in the center, at which point a movable roof is attached, which is easily raised or lowered at the will of a single manipulator. Its color is a grim and forbidding black, enlivened by the dull luster of many hundred metallic points; its material is paper, covered with pitch and profusely studded with tin nails. With its flapping sail-like roof and ebony hue, it has a weird and semi-nautical appearance, and the uncanny effect is not lessened when, at an imperceptible signal, the great building swings slowly around upon a graphited center, presenting any given angle to the rays of the sun, and rendering the operator independent of diurnal variations. The movable principle of this building is identical with that of our river swinging bridges, the ends being suspended by iron rods from raised center pots. The exigencies of natural lighting incident to the better "taking" of the subjects, and the lack of a suitable theatrical stage, etc., however, necessitated the construction of this specially devised building. This invention is due to Mr. Dickson, the chief photographer and engineer of the Edison laboratory. At the other end of the hall in this theater is a cell, indicated by an ordinary door and an extraordinary window, glazed in panes of a lurid hue, which gives the finishing touch to the Rembrandtesque character of the picture. The compartment is devoted to the purpose of changing the film from the dark box to the kinetographic camera, being provided with a special track from the mysterious recesses at the back of the stage to its own special precincts, where fresh films are substituted for the ones already employed. The process of developing, etc., is performed in the main photographic building of the Edison laboratory.

When any subject of a great magnitude is ready to be taken where there are more than one in number, they are kept as close together as possible, and exposed either to the glare of the sun, to the blinding light of four parabolic magnesium lamps, or to the light of twenty arc-lamps, provided with highly actinic carbons, supplied with powerful reflectors equal to about 50,000 candle-power. This radiance is concentrated upon the subject while the kinetograph alone, or in connection with the phonograph, is hard at work storing up the records and impressions for future production. For the reproduction of these photographic impressions a machine called the kinetoscope is made use of. It consists of a cabinet containing an electric motor and batteries for operating the mechanism which acts as the impelling power to the film. The film is in the shape of an endless band fifty feet in length, which is passed through the field of a magnifying glass perpendicularly placed. The photographic impressions pass before the eye at the rate

of forty-six per second, through the medium of a rotating, slotted disk, the slot exposing a picture at each revolution, and separating the fractional gradations of pose. Projected against a screen, or viewed through a magnifying glass, the pictures are eminently life-like, for the reason that the enlargement need not be more than ten times the original size. For exhibition purposes the projecting room must be hung with black, in order to prevent any reflection from the circle of light emanating from the screen at the other end, the projector being placed behind a curtain, also of black, and provided with a single peep-hole for the accommodation of the lens. The effect of these somber draperies, and the weird accompanying monotone of the electric motor attached to the projector, are horribly impressive, and one's sense of the supernatural is heightened when a figure suddenly springs into his path, acting and talking with a vigor which leaves him totally unprepared for its mysterious vanishing. Projected stereoscopically, the results are even more realistic, as those acquainted with that class of phenomena may imagine, and a pleasing roundness is apparent, which in ordinary photographic displays is conspicuous by its absence.

Nothing more vivid or more natural could be imagined than these breathing, audible forms, with their tricks of familiar gesture and speech. The inconceivable swiftness of the photographic successions, and the exquisite synchronism of the phonographic attachment, have removed the last trace of automatic action, and the illusion is complete. The few illustrations accompanying this illustration show in every one of the pictures, and each succeeding one of the rapid photographs taken the details of the movement made within the time to that of completion can be seen by examining them closely. The rapidity with which the impressions are made is such that it is interesting to notice the slight difference from one to the other. Taking for instance, the organ-grinder, the monkey jumps upon his shoulder, and if the phonograph attachment is connected, the accompaniment of a strain of music from the organ is also heard. The rich strains of a tenor or soprano are heard, set in their appropriate dramatic action, the blacksmith is seen swinging his ponderous hammer, exactly as in life, and the clang of the anvil keep pace with the with his symmetrical movements; along with the rhythmical measures of the dancer go her sounding footfalls; the wrestlers and fencers ply their intricate game, guarding, parrying, attacking, thrusting and throwing, while the quick flash of the eye, the tension of the mouth, the dilated nostrils, and the strong, deep breathing give evidence of the potentialities within. In fact, one can photograph by this means from every characteristic section of social, artistic and industrial life, and from many phases of animal existence. Still in selecting the themes for this rapid method of photography it needs utmost discrimination.

III. — THIS METHOD OF PHOTOGRAPHY IN THE SERVICE OF PHYSIOLOGY, PATHOLOGY AND LEGAL MEDICINE, ETC.

From what has been said and demonstrated in these pages, and can readily enough understand the object lessons taught us by these methods of rapid photography and the reproduction of its many graded animated photographs. What is the future of this all? Ask rather from what conceivable phase of the future

the kinetograph can be debarred. In the advancement of science in the revelation of unguessed worlds, in its educational and re-creative powers, and in its ability to immortalize our fitting but beloved associations, the kinetograph stands foremost among the creations of modern inventive genius. Mr. Dickson says, "It is the crown and flower of the 19th century magic, the crystallization of eons of groping enchantments. In its wholesome, sunny and accessible loves are possibilities undreamt of by the occult lore of the East; the conservative wisdom of Egypt, the jealous erudition of Babylon, the guarded mysteries of Delphic and Eleusinian shrines."

In the study of physiology the possibilities which are opened to us by this means are startling. No one can yet fore-shadow the coming researches to be made from time to time by this mode of rapid photography. Every phase of physiologic research will be possible. The microscopic lens and the kinetograph will be amalgamated into one and the infinitesimal world by this aid will yet be discovered. The pathologic symptoms usually witnessed in disease can be photographed, and life imbued into every one of them—thus giving us time to study them closer, and at leisure. The lecture room thereby will also be endowed with additional edification. This is an entirely new field which the modern explorer has got to travel and note down and make his geographic drawings yet.

To speak hastily here, the photographic art which was put early to the service of medical studies, was due the genius of Dr. Maddox of England, and who also discovered the bromid of silver gelatin emulsion process, and thereby bringing the photographic technique up to its high standard. The first who busied themselves with the experimental investigation in this line of photography were Marie and Czermak. They both made use of it in physiologic researches and even to-day some of their work can not be beaten: Czermak, also constructed the first apparatus for laryngoscopic photography. The pictures which were taken by this apparatus gave in detail every single part of the larynx. Since then others have photographed the larynx, by many different means. French of Brooklyn, N. Y., and myself also have done good work. Also we find that Ozolan of Paris in 1869 made use of the photographic process in physiologic studies, and specially designed a camera for photographing the heart beats. Since the early daguerreotype photography in medicine, many studies have been made in perfecting rapid and sensitive plates and those of Dr. Wm. G. Thompson's of New York City. With these he had been able to experiment in picturing the heart beats of animals and thus enlarged our knowledge in a heretofore unexplored field regarding the view of the diastole and systole of the heart in its movements in succeeding periods of time. This work promises to afford a valuable means of illustrating the action of drugs on the heart and of recording accurately any experimental observations upon the cardiac movement without the error of the personal equation of the observer. His photographs show a full diastole and a full systole, with a series of any number of intermediate views. These serve him as standards of comparison with photographs of the altered diastoles and systoles which occur under the influence of cardiac stimuli or depressors. There is no doubt that under such favorable scientific truths before us, Dr. Thompson can not fail to give us a full pharmacopeia and the therapeutics of the circulatory system and digestive

tract. But what lies in store for us by means of rapid photography with the aid of the kinetograph and kinetoscope is at present hard to say—as many wanting technical appliances in the shade of microscopic lenses, etc., are still being experimented upon in this domain.

So also with photographing the larynx, in order to show the living movements of abduction, adduction of the vocal bands, vocalization dynamics, and under their various pathologic conditions, etc., with some additional devices all this can not fail to be accomplished.

In the study of microscopic subjects, a class of special interest, as lying outside of the unaided vision of man, it may be said, that in the treatment of these infinitesimal types, much difficulty was experienced in obtaining a perfect adjustment so as to reproduce the breathing of insects, the circulation of the blood in a frog's leg, and other similar processes of nature.

Mr. Dickson with his high grade of mechanical skill overcame such obstacles as laid in his way and succeeded in photographing and enlarging the animalculæ in a drop of stagnant water in which these animalculæ are suspended, which proved to be an exacting task. This was accomplished by the aid of a powerful lime-light, concentrated on the water, by the interposition of alum cells for the interception of most of the heat rays, and by the use of a quick shutter and kindred contrivances, the obstacles were overcome, and the final results were such as fully to compensate for the expenditure and time and trouble. Mr. Dickson, in speaking of this result, says: "Suppose that the operator has at last been successful in imprisoning the tricky water goblins on the sensitive film, in developing the positive strip, and placing it in the projector. A series of inch-large shapes then spring into view, magnified stereoptically to nearly three feet each, grewsome beyond power of expression, and exhibiting an indescribable celerity and rage. Monsters close upon one another in blind and indiscriminate attack, limbs are dismembered, gory globules are tapped, whole battalions disappear from view. A curious feature of the performance is the passing of these creatures in and out of focus, appearing sometimes really of their own size and proportions."

One can not help wondering at the progress and future of this branch of the science and the many uses in which it has already been called into service, taking a survey from records of the infinitely little and the infinitely great from microscopy, which deals with the invisible, to the vastness of astronomic wonders. I could here go on and cite many more instances to which this mode of rapid photography in medicine and other sciences could be put to, but suffice it to say, from what I have hinted at will prove good in all undertakings where motion and animation is wanted in demonstrating them in the study of any subject.

All the foregoing finished experimental work up to the present time are but the heralds of those to come out of the multiplying schemes which are on foot. Hitherto the limitation has been to the consideration of detached subjects alone, all of which are most successful, but Mr. Edison and Mr. Dickson are increasing the facilities to such an extent—high is their ambition—that a number of actors can be put into a group and taken. Also to increase the stage appointments, with a view to the presentation of an entire play, set in an appropriate frame. This work once made appli-

cable in this line, it can be indefinitely extended to any given phase which is desired to be reproduced. They speak of their method so confidently that it points to ultimate success. Every day adds to the security and the celerity of their undertaking. No scene, however animated and extensive, but will eventually be within reproductive power. The advantages of this method are simply countless.

In these preliminary pages which I communicate to your body, I only touch upon the subject before me in a very primary way, and prepare you for that which will follow in detail in a near future. This, however, is enough to show you that the birth of animated photography has taken place, and its new era can now be hailed by exclaiming, Eureka!

Since this paper was read Mr. Edison and others have succeeded in so improving the kinetoscope that to-day we have the realization of the foreshadowing of that vitascope by which it is possible to witness moving life-size figures of men, women and animals when thrown upon the screen by means of bright lights and powerful lenses. The original photographs, as by the kinetoscope and developed on the film roll, are about the size of a special delivery stamp, and to produce a life-size picture they are magnified about six hundred times. Each vibration of the film, or the apparatus which revolves it, is magnified in like proportions. With these possibilities, the kinetoscope will be another important piece of apparatus added to those of recent discoveries, put to the disposal of medicine.

NOTE.—I wish to express my sincere thanks to Mr. Dickson, chief of the Edison Laboratory, for the many points herein given which were taken from his private notes and sketches.
460 Lexington Avenue.

SELECTIONS.

On an Unpublished English Anatomic Treatise of the Fourteenth Century.—At the annual meeting of the British Medical Association held in London, August, 1895. Payne¹ exhibited to the Section of Anatomy and Histology the manuscript of a treatise of surgery prefixed by a short treatise on the anatomy of the human body, written by an English surgeon and dated the year of our Lord 1392. The name of the author is unknown.

The date of this manuscript is of much interest. A treatise on anatomy and surgery by an English author, written in the English language of the fourteenth century is undoubtedly unique although it is quite possible, as Payne suggests, that the MS. treasures of the British Museum and other great libraries may be found to harbor similar productions. The only documents comparable to it are the works of John Arderne, the translations of Lanfranc's Surgery, and translations of the French surgeon Henri de Mondeville. Payne calls attention to the importance of the fourteenth century in the history of English science as of English literature and theology. In literature and theology the verse of Chaucer and the prose of Wycliffe are sufficient examples. In science we have the notable work of John Arderne, the first English surgeon. The fifteenth century was uneventful. The Black Death and succeeding pestilences, and the wars of the Roses brought the progress of science and medicine in England almost to a standstill so that in the sixteenth century "when the revival of learning and the introduction of printing led men to take stock of their intellectual possessions, little more was done in practical medicine than to gather up the threads of the fourteenth century tradition." The works of Arderne and the unpub-

lished treatise here mentioned had an extraordinary resurrection in the middle of the sixteenth century. The document of the unknown writer was a folio on paper, in double columns of 190 leaves, written in a very fine and very legible black letter. It may interest many of our readers to reproduce the preface as read by Payne:

"The Holy Trinity that is head and well of cunning, giver and graunter of grace to all tho that by her power trevailen truly about science and cunning; that is help and edification to his people, graunte you grace that this compilation shall have so for the usen and disposen the fruyt of medicyns and of worchyng in it conteyned that it turne specially to the worships of God and profit of the peple. The which compilation of sirurgie I have compiled and drawn aftir the discreet autoritie of my moost worshipful maistris and predecessours of the same science. And specially aftir the noble counsell of my worthi maistir Lanfranke, puttyng therto worchyng that I have assaied and proved in my tyme and other expert medicyns y gaderid of dyvers worcheris that they also have assaied and proved, y compilid and endid in the year of our Lord MCCCCLXXXII. Wherefor I prie and counseile you that usen the worchyng in this doctrine, contynue that ye ben gracious and helpinge to the pore for Goddis sake, and to the riche for a competent salarie, and also that ye seien for his soule that compilid this tretis, and for all tho that helpide therto and for alle cristen a paternoster and an ave marie. And though it be so that I y sum tyme addyng and sum tyme with drawyng have transposid the ordynance of thes myn aforseid maistreis, and so by cause of ignorance have fallen othir while in to errour, I biseche you tendirly that it schal reden or heren or undirstonden that ye have me excusid, and that ye adden and fulfillen benygly the defaultis in it conteyned after the decre of the worshipful Galen in the ij De morbo et accidente, and in the v and in the last chapitre leggyng this text. Olde mennys sawis schulen be declarid frendly of here feloweris, and if ther failen any thing, it schal ben bi hem benygly fulfilled."

The first part includes the anatomy. It is divided into three sections called "Distinctions." The classification is as follows:

"The First Distinction hath seven chapters; treats of the definition of anatomy, and of embrion, and of all his consimilar members: 1, Definition of Anatomy; 2, Anatomy of Embrion; 3, Anatomy of Marrow, Bones, and Gristles; 4, Anatomy of Ligaments, Sinews, and Cords; 5, Anatomy of Arteries, Veins, and Gristles; 6, Anatomy of Brawnes, Lacertes, and Villis; 7, Anatomy of Fatness, Skin, Hair, and Nails. The Second Distinction hath fifteen chapters; treats of a man and all divers members: 1, Anatomy of the Head; 2, Anatomy of the Forehead; 3, Anatomy of the Eye; 4, Anatomy of the Nose; 5, Anatomy of the Mouth; 6, Anatomy of the Neck; 7, Anatomy of the Shoulder; 8, Anatomy of the Arm; 9, Anatomy of the Breast; 10, Anatomy of the Wombe; 11, Anatomy of the Matrice; 12, Anatomy of the Haunches; 13, Anatomy of Manne's Privy Members; 14, Anatomy of the Thighs, Legs, and Feet; 15, Recapitulation of all the Bones in a Man's Body. The Third Distinction treats of the four complexions, with the signs of the Zodiac, and has ten chapters."

Anatomy is defined according to Henri de Ananda Villa (Henri de Mondeville) thus: "Anatomy is the rightful division and knowing of a man's body, and of his single parts and members, the which body is the subject or the matter of all science of medicine and of sirurgery." The anatomy is a compilation from several authors but chiefly from Lanfranc, of Milan, and Henri de Mondeville. Lanfranc was born in Milan about the middle of the thirteenth century and died in Paris about 1306. His chief work was the *Chirurgia Magna* and the unknown author of this MS. quotes very liberally from Lanfranc's work. Henri de Mondeville, or de Ananda Villa, was a French surgeon, who died about 1320, whose name after centuries of neglect, has lately been brought into prominence and whose writings, thought to no longer exist, have recently (1893) been published in Latin and French. The French edition published by M. Nicaise, was reviewed editorially in the number of this JOURNAL for April 28, 1894. Our unknown writer follows precisely the arrangement of Mondeville as far as anatomy is concerned; he also quotes Mondeville by name very often. While this treatise appears to be founded entirely on the works of Lanfranc and Mondeville, there is one feature about the

¹ British Medical Journal, Jan. 25, 1896.

manuscript which Payne says shows that the writer, though a compiler, had a distinct individuality. He practiced in London. He speaks of the inefficacy of operation in carcinoma of the breast as follows:

"And furthermore to speak of this sikenes in woman's pappes, there was a worshipful riche woman in London in my tyme, the whiche had such a canker in her pappe, to whom weren clepid the most discrete worcheris of the Cyte, both of fisik and surgerie, among whom I was present, and worching in the same cause. But I seie surely evermore the malice encrease from day to day, and for al that we myghten do the sycknesse was so fervent that it profitid ful litil to the patient, so that not agenstondynge al our craft and cunnynge at the laste it is woundid and so the woman diede withynne short tyme aftir."

Speaking of the number of bones in the human skull, which was a disputed question, he says:

"But though it so be that we have tretid in this partie of these vi. bonys in the heed that ben necessarie to the dosinge and difference of the brayn. Nethelless we afferme not that ther beth sicke vi. bonys in ech mannys heed ffor truly I foond in the charnel of Seynt Marie spetil at London a scolle bone that was al oon hool boon lik a basenett, outtaken oonliche the ij. small petrouse bonys and the nether chekebon," etc.

In one part of his treatise he speaks of the four complexions or temperaments: sanguen, coler, fleume and melancholie, and their connection with the signs of the Zodiac, the four elements, the course of the planets, etc.

The fate of this manuscript is interesting. It appears that it was copied and issued under another name as the author. Payne shows that the little work known as Vicary's Anatomy, printed in 1577 as: "A profitable Treatise of the Anatomy of Man's Body," must have been an almost actual transcript of the work of the fourteenth century surgeon. There are such extraordinary verbal agreements in Vicary's book with our author that any other interpretation is hardly possible especially in view of the fact that no reference to the literature published in the two intervening centuries is made in Vicary's book which would undoubtedly have been done had he compiled a work on anatomy. It may be concluded that Vicary was in possession of a copy of this hitherto unpublished MS. of which he made an abridgement. One does not like to look upon Vicary as an impostor, and there is, as Payne states, another supposition. Possibly Vicary did not profess to be the author. The only known printed edition of his work was brought out fifteen years after his death by his colleagues at St. Bartholomew's Hospital, and they may have found a manuscript tract which they regarded as Vicary's, though he had never claimed it as his. In any event the real author was the anonymous writer of the fourteenth century, about whom it would be extremely interesting to learn more.

The Pain of Renal Stone.—Before the Medical Society of London, Mr. Hurry Fenwick read a paper on the above subject, as reported in the *British Medical Journal*. He has had a series of uncomplicated nephrolithotomies to account for the difference which appeared to exist in the character and severity of the pain produced by stone in the kidney. He asserted that uncomplicated stones in the kidney could be divided into three classes: a, those lying loose in the pelvis; b, those under the capsule lodged in the cortex of the kidneys; and c, those contained in the fleshy part of the kidney, the columns of Bertini or pyramids. The pain and suffering in loose pelvic stones were usually typical. They evoked colics, radiations, and often bladder symptoms. The cortex stones did not evoke colics, radiations, or bladder irritability, but merely a severe fixed pain. The intermediate group (the parenchymatous class) partook of the characters of both, for the hollows in which they lay often communicated with the pelvis by fine channels. One prominent symptom seemed in many instances to separate the embedded stones from the pelvic stones. In the cortical stones the patient was forced to sleep on the kidney in which the stone was lodged, but could not turn, without pain, on the healthy

side. Often in the pelvic stones the patient lay on the kidney of the unaffected side. Another sharp line of difference between the cortical and the pelvic stones was found in the urine. Pelvic stones usually caused pus in the urine within a year or so, but the cortical stones did not change the character of the urine, even after twenty or more years. "Dr. Rolfe followed with a paper on the cases of renal pain calling for medical, as distinguished from surgical, treatment. He divided the cases into those in which the pain was dependent on reflex nervous disturbance, and the so-called 'aching' kidney. The former is met with in association with valvular disease of the heart, more particularly aortic, and thoracic, and especially abdominal, aneurysm. The aching kidney, he suggested, was usually due to movable kidney, but was also met with as the result of tight-lacing, and from undue acidity of the urine or other excess of some normal constituent of the urine."

Epidemic, Rapid Termination of Diseases.—At a recent meeting of the Brussels Academy of Medicine, Rommelaere called attention to the peculiar asphyxia which so often occurs in diseases apparently progressing favorably, amounting at times almost to an epidemic. He does not refer to acute fevers, but to the cases of bronchial catarrh, chronic phthisis, typhoid fever, diphtheria, etc., which show no symptoms of a speedy fatal termination, and especially the cases of influenza. All is going well, auscultation indicates nothing definite, the prognosis is favorable, when suddenly the scene changes, intense dyspnea supervenes, with cyanosis, coma and fatal asphyxia, no medication produces any effect, and the patient rapidly succumbs. The necropsy reveals lesions indicating atelectasis. The pulmonary artery is choked with a clot, and the bronchial arteries are engorged. Repeated experiments showed that if a coloring liquid is injected into such a lung, the vascular arbor is colored by it, but the unexpanded portion is unaffected by it. If atelectasis is produced in a rabbit by the creation of a pleural fistula, and a coloring liquid injected, the sound side alone is affected by it. Even when the unexpanded portion is insufflated with air, the coloring liquid still does not pass into it. If an injection of methylene blue is made in the jugular of a rabbit in this condition, the sound lung alone shows the effect of the coloring matter. Rommelaere concludes from these facts and various experiments that this condition is due to arterial lesions and to some change in the blood, and sometimes to the presence of air in the pleura. This effect upon the vascular walls of the lesion of the blood in the circulation has already been noticed, especially in tuberculous phlegmasia, and modern bacteriologic investigations have distinguished the presence of the Koch bacillus, where the necropsy once revealed merely the simple fact of the obliterating arteritis. Rommelaere states it as his opinion that it will be found before long that the pneumococcus and staphylococcus are also capable of producing the same phenomena. It is already proved that Eberth's bacillus can penetrate the vascular walls and produce changes in the endothelium.—*Semaine Médical*, February 12.

The London Lancet Holds Out the Olive Branch.—The *Boston Medical and Surgical Journal* commends the course of the *Lancet* in its antagonism to the war spirit. It says: "In a recent issue the *Lancet* alludes editorially to the intimate and beneficial character of the mutual intercourse between English and American medical men during the last generation, and points out that if the question of peace or war were referred to medical men, there could be no question of the continuance of cordial relations. In the same issue, Dr. T. Lauder Brunton, under the title of 'Psychology of President Cleveland's Message,' points out that that message, while apparently warlike, was really pacific, and the time chosen, just before the Christmas season, was especially favorable for the two great nations which it concerns to put the proper, that is, the peaceable, interpretation upon it. The friendly feeling between the mem-

bers of the learned professions in England and this country is certainly a matter for congratulation, and it is pleasant to know that the influence of our valued English contemporary is for peace and good will."

Antiseptic Value of Subnitrate of Bismuth.—Since the introduction of naphthol, salol and salicylate of bismuth, our old friend, subnitrate of bismuth, is being neglected and some even assert that its action is merely plastic or mechanical, and declare that its action is valueless. But they are mistaken: it is a powerful bactericide: applied to wounds it heals them: arrests inflammation, suppuration and all putrid conditions, and owes to its microbe-destroying properties its recognized efficacy in gastrointestinal disorders. These properties have been proved in many experiments, especially those of Gayon and Dupetit with the ferments of new wine. Its fine effects in fistulas and urethritis are evidently due to this cause also. The moment it comes in contact with moisture it seeks to resolve itself into its elements, oxid of bismuth and nitric acid, which readily explains its antiseptic action, for, as Duclaux remarks: "The presence of even a trace of nitric acid in an organic solution arrests the development of a host of microbes." The oxid also has germicidal properties. And this is not all. As soon as the subnitrate of bismuth reaches the intestines, it meets sulphohydric vapors which transform it into black sulphur, and thus liberate another acid and generate nitric vapors, which have a special antiseptic action on the putrid gas producing bacteria, as is well known. But in order to be effective it must be absolutely pure, not mixed with carbonate like the kind known in trade as "light subnitrate." Another important point is that it should be very finely pulverized: large grains become coated with the black sulphur and the inside remains intact, which accounts for the fact that the same dose to the same patient often produces different effects. CARLES in the *Archives Clin. de Bordeaux*, February.

AN ALBUMIN TESTER FOR URINE.

By JOHN W. ONEILL.
CHICAGO.

This Albumin Tester is designed to simplify and to increase the delicacy of the nitric acid test for urine. The apparatus is blown from glass tubing and bent in the form of the letter U. One limb, two inches in height and five-eighths of an inch in diameter, is practically a test tube. To the bottom of this and

curved upward to form the second limb of the U is a capillary tube, the open end being enlarged to form a small funnel. A narrow strip of black one-quarter of an inch wide extending from the top to the bottom of the large tube, for a background, will be an advantage. This can be painted or a strip of black paper fastened to the glass.

The urine to be tested is poured into the large tube until it reaches the level of the bottom of the funnel in the capillary tube ("A" in cut). The nitric acid is then dropped into the funnel: it passes down the capillary tube and up under the

urine in the large tube without disturbing or mixing—lifts it up, so to speak. If albumin be present it is shown by a delicate white line.

1421 North Clark Street.

NECROLOGY.

WINTHROP SARGENT, M.D., who was at one time a prominent physician of Philadelphia, died March 16 at Roxbury, Mass., where he had resided and practiced his profession for several years. He was born in Gloucester, Mass., on July 8, 1822, and received his education in Dartmouth College, and subsequently studied medicine at the University of Pennsylvania, from which institution he was graduated in 1847. He entered upon the practice of his profession in Montgomery County, where he remained until 1855, when he removed to Philadelphia. He was for many years secretary and afterward president of the Montgomery County Medical Society. While in Philadelphia he was school director for six years. He was appointed surgeon in charge of the Government Hospital in Kingsessing in 1862. Not long after that his wife died and he removed to Boston.

WILLIAM SAVERY, M.D., died at his residence in Philadelphia March 13. Dr. Savery was attacked with the grippe about Christmas, which brought on rheumatic gout, to which his death is ascribed. Dr. Savery was born in Philadelphia Oct. 20, 1832. He was graduated from the Philadelphia College of Pharmacy in 1854, and was appointed resident apothecary and medical registrar at the Friends' Asylum for the Insane, and served in that capacity till 1860. He graduated at the University of Pennsylvania in the medical class of 1861, and was resident physician in the Wills Eye Hospital from 1861 to 1862. From April, 1862, to October, 1863, Dr. Savery was resident physician in the Pennsylvania hospital. He was also volunteer surgeon in the United States Hospital at Fredericksburg, Va. From 1870 to 1871 Dr. Savery was physician to the Winnebago tribe of Indians in Nebraska under appointment of General Grant. From 1872 until 1888 he was attending physician to the Hospital of the Good Shepherd near Bryn Mawr, where he engaged in private practice. Since that time he led a retired life.

JOB SYMMES CRANE, M.D., who died at St. Augustine, Fla., on March 26, was the senior practitioner of Elizabeth, N. J. He was in active practice until about two years ago, when he was taken with an apoplectic attack. Paralysis resulted, and he was lately sojourning in Florida, in the hope of receiving benefit to his health. He was a native of Elizabeth and a graduate in arts at Princeton College, and in medicine at the New York College of Physicians and Surgeons, class of 1849. He was a member of the New Jersey State Medical Society and of the AMERICAN MEDICAL ASSOCIATION as long ago as 1871. Dr. Crane was for many years one of the directors of the National State Bank and was one of the founders of the Union County Medical Society and an ex-president of the same. He was at the time of his death, president of the Union County Savings Bank, and one of the directors of the Home for Aged Women. He was also ex president of the staff of the Elizabeth General Hospital and Dispensary, institutions which he helped to inaugurate in 1877.

THOMAS M. FRANKLIN, M.D., who died at Greenwich, Conn., March 22, was a graduate of the medical department of the University of the City of New York, class of 1847. He was one of the physicians to the Eastern Dispensary from 1847 to 1851, and a ward cholera physician in the early summer of 1851. He afterward held office in the Thirty-fifth Street Cholera Hospital. He was assistant physician at the Government Hospital for the insane in Washington from 1865 to 1872, and medical superintendent of the New York City Lunatic Asylums on Blackwell's Island and Hart's Island from 1878 to 1886.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

PER ANNUM, IN ADVANCE \$5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, APRIL 11, 1896.

PRACTICAL AIDS IN THE DIAGNOSIS OF PERICARDIAL EFFUSIONS, IN CONNECTION WITH THE QUESTION AS TO SURGICAL TREATMENT.

Pathologists are well aware of how often pericarditis with effusion is not recognized clinically. OSLER says in his Practice of Medicine that probably no serious disease is so frequently overlooked by the practitioner. The prognosis in extensive purulent effusion is grave. Medical treatment is practically of little avail and the results of paracentesis of the pericardium have so far been rather disappointing. An early and radical operation ought to increase the percentage of recoveries. A necessary prerequisite for operative treatment is a reliable diagnosis. EWART,¹ the well-known writer on physical diagnosis, summarizes in a timely article numerous practical points to aid one in the diagnosis of pericardial effusion, especially when this is large enough to raise the question as to surgical interference.

EWART, stimulated by an early mistake, worked out for himself a complete method of physical examination, the underlying principles in which are: 1. accurate percussion and palpation; 2. careful auscultation; and 3. observation of the pulse. He discusses under separate headings the following signs, some of which are new:

1. Considerable extension of the lateral boundaries of the total area of dullness. Careful percussion will guard against the mistake of narrowing the outline of the sac on account of the superficial resonance of the borders of the lung, which overlap the sac instead of coinciding with its lateral boundaries.

2. Great extension of absolute dullness: the sternum absolutely dull. This sign is not absolutely diagnostic,

because it may be due to a number of conditions that will separate the two upper lobes of the lungs, such as a much enlarged heart, aneurysm, mediastinal tumors, etc.

3. The depression of the liver. In no other condition except in pneumothorax and in thoracic sarcoma is the hepatic depression so marked, at least in the middle line, as in large effusions into the pericardium. The hepatic percussion note may begin at the level of the tip of the xiphoid instead of at the infrasternal notch.

4. Dullness in the right fifth intercartilaginous space (ROTCH'S² sign). As a result of pericardial effusion within the right corner of the sac, the usually resonant area in question may become dull on percussion. EWART regards this sign as possibly present in certain cases of enormous dilatation of the right auricle from tricuspid stenosis, and hence not sufficient to supply the diagnostic verdict.

5. The diagnosis between pericardial effusion and cardiac dilatation. The lower angle of the pericardial dullness projects to the right. Normally the right auricular border is convex, it retires downward and inward toward the xiphoid. The outline of an effusion of fluid spreads out at the base, its lowermost angle projects outward. "From a surgical standpoint the practical importance of this sign, which seems to be the only one establishing a diagnosis between pericardial and cardiac dilatation, lies in the fact that aspiration of a dilated right auricle has been repeatedly recorded." A faithful mapping out of the right border of dullness is necessary.

6. The lower left angle of dullness, the relation of the apex beat to this angle. In cardiac enlargement or displacement the apex beats at the extreme left limit of the dullness and at its lowest level. Not so in pericardial effusion. The apex will beat somewhat inside and above the boundaries of dullness.

7. The first rib sign. In all cases of considerable pericardial effusion it was possible to feel the upper edge of the first rib; this means a rising up of the clavicle. This condition also occurs in some cases of dilatation of the heart. It can be easily studied without disturbing the patient.

8. The posterior pericardial patch of dullness. Whenever fluid accumulates in the pericardium the resonance at the left posterior base is modified in a most definite manner. A patch of marked dullness is found at the left inner base, extending from the spine for varying distances outward. When all the signs in front support the diagnosis of effusion, the presence of this posterior patch of dullness furnishes a complete and crucial evidence of fluid.

9. Tubular breathing below the right mamma. This sign is not constant, but should be looked for in severe cases.

¹ British Medical Journal, March 21, 1896.

² Boston Medical and Surgical Journal, 1878, Vol. xcix, p. 427.

10. The posterior patch of tubular breathing and egophony. "Immediately below or slightly to the left of the tip of the left scapula a patch of about two inches in diameter presents well-marked tubular breathing and egophony." This is confirmatory of other signs. It is generally present.

11. The secondary pleural effusions. The occurrence of pleural effusions belong to the latter stages of pericardial effusion, and their diagnostic value is therefore diminished.

12. The large and slapping pulse of pericardial effusions. The peculiarity of the pulse is its great size and velocity of impact, and the sudden collapse of the wave.

It will be seen that EWART has supplied available signs that are novel and which, in conjunction with others commonly described, may facilitate the diagnosis. He cautions against the expectation of finding the classical account of the disease directly and wholly applicable to individual cases. Irregular cases of pericarditis are common and of special importance to the surgeon.

OYSTER SHUCKER'S KERATITIS.

DR. ROBERT L. RANDOLPH has a long article in the *Johns Hopkins Hospital Bulletin* on the above named affection. It is a traumatic affection due to an injury from a particle of an oyster shell, and is chiefly remarkable for the rapidity with which infiltration appears at the seat of the wound, in marked contrast to the history of wounds by other kinds of foreign bodies of the same size and in the same location.

A small particle of the oyster shell is violently chipped off by the hammer that is used in the shucking process, and it flies into the eye. The particle is generally too small and too light to penetrate to any distance into the cornea. Large pieces, however, are sometimes detached and are driven through the entire thickness of the cornea, and when such a thing happens loss of the eye usually results. This occurrence is happily rare. Unlike other foreign bodies that lodge in the cornea, the particle of shell can seldom be detected. This is probably due to the fact that in the rapid infiltration that takes place the particle of shell is thrown off.

The use of the hammer to break off the edge of the shell before introducing the knife blade constitutes the chief element of danger in oyster shucking as practiced in Maryland. In other sections, as for instance, in the far South and down East, the shucker dispenses with the hammer and sticks in the point of the knife at once in order to pry open the shell. This no doubt explains why the disease is seldom seen in the portions of country just mentioned.

DR. RANDOLPH'S study of the disease involved a careful bacteriologic investigation yielding the following conclusions:

1. Oyster shucker's keratitis may be defined as a traumatic keratitis where the injury is produced by a particle of the oyster shell.

2. The disease is chiefly remarkable for the rapidity with which the cornea undergoes necrosis at the site of the injury, this area of necrosis being usually very small, owing no doubt to the small size of the foreign body. Small foreign bodies of copper, steel and sand usually produce no appreciable keratitis; and even when they lodge in the cornea, commonly require several days to cause a noticeable inflammation. On the other hand, the oyster shucker presents a marked infiltration of the cornea at the point of injury within twenty-four hours after the accident.

3. This decided reaction on the part of the cornea makes the injury a peculiarly dangerous one when a large area is wounded, or when entrance has been made into the anterior chamber, such conditions in my experience being invariably followed by loss of the eye through panophthalmitis. How often do we see the cornea injured in the same degree by other kinds of foreign bodies and still the vision not entirely destroyed?

4. Bacteriologic investigations failed to discover any specific organism, nor did any of the organisms obtained from cases of oyster shucker's keratitis manifest any pathogenic properties when introduced into the cornea of rabbits, with the exception of the pyogenic cocci. It is not likely then that the disease is of parasitic origin.

5. The carbonate of lime, of which the oyster shell is almost entirely composed, was found to possess qualities irritating enough to call forth a keratitis when introduced into the cornea of a rabbit, and it is more than probable that several other chemie ingredients of the shell would be more or less irritating to the cornea.

6. It is certain that bacteria always play a part in traumatic keratitis, but it is evident that in this variety of traumatic keratitis the cornea is rendered especially susceptible to the effects of microorganisms, by the irritating chemie ingredients of the oyster shell, notably the carbonate of lime.

Baltimore is the greatest oyster market in this country; there are at least six thousand shuckers in Maryland, and most of these are found in the shucking houses of Baltimore. In many of the northern cities, as for instance in Portland, Boston and New York, oysters are received in great quantities that are shucked in Baltimore, so that oyster shucking in those cities evidently does not exist as a trade to the extent that it does in Baltimore. The magnitude, then, of the oyster industry in that city may be said to account for the frequency of oyster shucker's keratitis.

REPORT OF COMMISSIONER OF EDUCATION.

The Report of the Bureau of Education, just issued, contains a valuable report on medical education that has already been editorially summarized in this journal. It is, however, so suggestive in some of its facts and details, that one is fully justified in referring to it again.

The details given of the requirements for entering on the practice of medicine in the different States are perhaps the most suggestive of all. The report truthfully says that the advance in this respect is the greatest that has been made in the history of medicine in this country. In eighteen States, it says (the number now is twenty or more), a mere diploma is no

qualification, but the candidate must pass a satisfactory examination as to his fitness, and there is now hardly a State or Territory where some sort of medical practice act is not in force. Imperfect and unsatisfactory as many of these yet are, they are indications of progress and a promise of better things. It is to the credit of the State of Illinois that much of this progress is due to the work of her State Board of Health while under the leading influence of the late DR. JOHN H. RAUCH, and it is to be hoped that it will not be long before she will again take front rank in the reform of which she was, in a sense, the pioneer.

An aspect of these legal enactments that, while apparent enough, may not have been fully considered by the profession as a whole, is the influence they have exerted and will exert still more in the future on the institutions for medical education in this country. At the date of the report (1893) there were 132 medical schools in the United States, and this number has undergone a considerable addition since that time. We are yet in the period or stage of growth in this respect, probably at its acme, and the reaction, it is possible, may not be very far ahead. This practice of publishing the results of examinations for admission to practice with the figures or percentages of failures by graduates of the different colleges can not fail to have a certain influence in some ways, though the statistics may be occasionally somewhat deceptive and require qualifying allowances. The requirements of a greater number of years of study and attendance will probably tend to extinguish in time some of the weaker and more poorly equipped institutions, as students will hardly be likely to wish to spend four years in colleges with what PROFESSOR WELCH calls a "pathetically meagre outfit," and one that can scarcely afford them the means of fitting themselves to pass any really practical examination. The additional requirement of an ante-matriculation examination which appears to be now coming in vogue, and which, like the others, is likely to become generalized throughout the country, seems also unfavorable to low-standard medical colleges. Whether these will continue to exist, supplying rural practitioners, while the higher grade institutions meet the wants of the urban practice, as MR. ERSKINE MILLER appears to infer, is more than doubtful, unless we assume, without any reasonable grounds, that the reform movement is to stop short of the point it has already reached in some parts of the country. There is, moreover, no class of medical men who need to be better fitted for their work than the country practitioners, and they often show that they are able to meet the requirements. With increasing age of the community, the conditions will approximate to those of other long-settled countries, and a high standard will be exacted as well in the country as in the city. The degree of prior education, within certain limits, has, however,

only a partial bearing on the qualifications for practice, and it may be that some schools will revert to the old practice of giving the M.B., or the licentiate degree instead of the at present universal Doctor of Medicine, according as the candidate has had a collegiate or university education or its equivalent, or not. It is certainly one of the possibilities of the present tendency of change in the matter of medical education.

There is, however, one tendency in the medical legislation of the day that is possibly not altogether to be commended; that is the tendency to make the medical practice acts too rigid and inflexible so that instead of only fulfilling their legitimate function of ruling out incompetents and quacks, they may exclude from practice within their territory even some of the highest qualified members of the profession. A law that makes attendance on three or four courses of lectures of a prescribed length, within as many consecutive or separate years prior to graduation, an absolutely essential condition before a candidate is even admitted to examination, will make it impossible for a physician to qualify who had received his degree in the bad old days (not so very remote) when inability to pass for a diploma after two courses was considered a sign of deficient intellect, and would put an actual premium on the dullards of those times. A man who can not meet these requirements may have been a student and investigator for all the intervening years since graduation and have made a national reputation that has caused him to be called to high professional positions for which he is disqualified by the provisions of the law. The demand for such provisions or for the expurgation from the law of clauses intended to meet such cases as are mentioned above is not, to say the least, wise or discriminating, or in accordance with the best interests and traditions of an honorable and learned profession. There is no danger of overcrowding the ranks if the qualifications are made sufficiently high, and these can be determined in any case without the universal application of rules that, however good they may be in general and in intention, are in exceptional cases abused. The exceptions taken by a metropolitan medical journal to the clause in the New York act which was evidently intended to meet such cases, are therefore not so much in the line of progress and virtue as their writer seems to think. Our medical legislation should be guided and inspired by a liberal scientific professional spirit and good Anglo-Saxon common sense, and while its enactments should be efficient and comprehensive they should also be in all things reasonable. We need no Chinese standards here.

VISUAL PROBLEMS IN MOUNTAIN CLIMBING.

The African explorer HENRY M. STANLEY, in *Science*, comments upon the experience of BONVALOT

and other mountain climbers in respect of the perception of distance:

"I do not know that the attention of psychologists has been sufficiently called to the experience of mountain climbers as bearing on the problem of the perception of distance. Both SIR MARTIN CONWAY in his recent book, 'The Alps from End to End,' and M. BONVALOT, in his book, 'Across Thibet,' have some suggestive remarks of the same general tenor on this subject, but I will quote only those of M. BONVALOT, as they seem on the whole the most pertinent. Speaking of the highlands of Thibet, he says:

"It is difficult to imagine how hard it is to find one's way among these highlands, where a man loses all sense of perspective, his eye wandering over immense spaces without seeing, at given distances either trees, houses, human beings, animals or edifices, the height of which is known to him. It is by the incessant and unconscious comparison of such objects as these that he has learned to form an idea of distance. Here in the desert we have in a few weeks lost this sense of distance which we had gained by the experience of our lifetime. All that one sees is so alike; one hill is like another; according to the time of day a frozen pool either sparkles in the sun or disappears, so that one does not know whether it is large or small; a little bird fluttering its wings upon a clod of earth looks like a wild animal which has been lying down and is getting up; a crow flying away with its prey in the morning mist seems to be a gigantic condor carrying off a lamb in its claws, while at sunset this same crow, cleaning itself on the summit of a rock, looks the size of a yak or a bear."

"It is plain from this experience that M. BONVALOT happened upon a new spatial world of size and distance, which he had to learn by a method of local visual signs, just as in infancy he learned the space world of the nursery room. It would be interesting to inquire of such travelers the exact nature of the signs they used in constructing the new space world."

THE UNWELCOME "EX."

We observe with sincere regret that a few of our exchanges are regularly printing items from the JOURNAL and simply crediting them to "Ex." Under our copyright and the order of the Trustees, we will be obliged to bring to legal notice those who continue these annoyances. The Trustees have given free and full permission to medical journals to republish any item that appears in the ASSOCIATION JOURNAL, but it is intended as a matter of common courtesy that due credit shall be given, and the general permission contains a proviso to that effect.

THE MEDICAL COLLEGE ASSOCIATION will meet on Monday, May 4, at 4 P.M. Gentlemen going by the JOURNAL Special will arrive in Atlanta in ample time.

CORRESPONDENCE.

"She has Suffered Many Things." Another Case.

NEW YORK, April 2, 1896.

To the Editor:—By request I report a case to go along with that of Dr. Cory's reported case, Vol. xxvi, p. 587 of our JOURNAL.

Some ten years ago a middle-aged widow presented herself for treatment, and the examinations disclosed the following:

1. Antelexion and hyperesthesia of the uterus.
2. Asthma, shown by dyspnea.
3. Bright's disease of the kidneys, shown by albumin, casts and fatty epithelia.
4. Fibroid tumor attached to the fundus of uterus, globar, pedunculated, about three inches and a half in diameter.
5. Pleuritis, shown by pain and friction sounds, about lateral third of chest.

6. Tuberculosis of lung, shown by impaired resonance on percussion, crackling respiration, elastic and inelastic lung fibers in sputum and the morphology of tuberculous blood.

This case was treated on the Salisbury plan. 4, disappeared in two months; 1, was hard to cure; 5, speedily disappeared; 3, also; 2, occasionally reappears; 6, disappeared and has reappeared, but now is in abeyance.

This case shows what perseverance will do in most unfavorable circumstances, where the principle is adopted of stopping causes, sustaining nature, oiling the machine with medicines, saving and conferring vital force and letting nature do the cure, as she always will if she has a chance.

Respectfully yours, EPHRAIM CUTTER, M.D.

Transactions Pan-American Medical Congress.

HARRISBURG, PA., April 5, 1896.

To the Editor:—Will you kindly inform me through the JOURNAL, whether members of the Pan-American Medical Congress who paid their \$10 fees are entitled to the Transactions of the meeting? If so, are they published yet, or if not, when and where can we obtain them? I have written to Dr. Reed, the Secretary, twice, but can not get an answer from him. If I am entitled to a copy, and they are published, I would like very much to have my copy.

Yours truly, J. WALTER PARK, M.D.

ANSWER: Write to Professor Wm. Pepper, Philadelphia.

A Wise Suggestion.

PHILADELPHIA, April 6, 1896.

To the Editor: In view of the vital importance of the subject others of your readers like myself would doubtless like very much to have from Dr. Halderman himself the details of the case of "Death from Antitoxin," reported by Dr. James L. Taylor in the correspondence of your issue of April 4.

Respectfully, JAMES TYSON.

"Our Journal."

FARMLAND, IND., March 10, 1896.

To the Editor: Like the "general practitioner" of medicine in a backwoods district, I presume the editor of a medical journal at his desk, is not burdened with compliments of his success, but I wish to say to you that I appreciate the ability with which "our JOURNAL" is conducted, and the advanced views and literary skill of its editorials.

Very respectfully, LEWIS N. DAVIS, M.D.

NEW YORK, March 24, 1896.

By the way, the issue of March 21, which I have just received, is the best for a long time. The topography is beautiful, the make-up admirable, the cuts clean, the contents interesting. Well done, thou g. and f. s.

Yours truly, A. L. G.

BOOK NOTICES.

Handbook for the Bio-Chemical Laboratory, including methods of preparation and numerous tests arranged alphabetically. By JOHN A. MANDEL. 12mo. Cl. \$1.50. New York: John Wiley and Sons. London: Chapman and Hall, Limited. 1896.

We can not better set forth the aims and purposes of this laboratory guide than the author has done in his preface:

"An attempt has been made to give concise directions for preparing the most important substances that enter into the composition of the fluids and tissues of the animal body. The methods herein presented are compiled from the most recent and important works on physiological chemistry; and in certain instances two or three procedures are given for obtaining the same result. The two hundred or more tests are arranged in alphabetical order; and the name of the scientist who suggested the test, or the name under which it is ordinarily known, is given in each case."

The work has been carefully and conscientiously done and the book will be found very useful by those engaging in laboratory work.

Uric Acid as a Factor in the Causation of Disease, a contribution to the pathology of high arterial tension, headache, epilepsy, mental depression, paroxysmal hemoglobinuria and anemia, Bright's disease, diabetes, gout, rheumatism, etc. By ALEXANDER HAIG, M.A., M.D. Oxon., F.R.C.P. Third edition, with fifty-four illustrations. Philadelphia: P. Blakiston, Son and Co. 1896. Pp. 600, 8vo. Cl. Price \$3.

This book which has now reached its third edition contains a vast amount of information upon the physiology of the production and elimination of uric acid and urea, and the pathologic changes caused by the retention of these excrementitious substances. The relations between certain forms of headache, mental depression, Raynaud's disease, rheumatism and uric acid are so clearly set forth with mathematical accuracy.

The author was himself a sufferer from the gouty diathesis, and has learned to control it practically by a suitable vegetarian and non-alcoholic dietary.

An Inquiry into the Difficulties Encountered in the Reduction of Dislocations of the Hip. By OSCAR H. ALLIS, M.D. The Samuel D. Gross Prize Essay. 8vo. Cl., pp. 167. Philadelphia: 1896.

In this excellent monograph, the author has apparently thrown light upon some details of the mechanism of hip joint dislocation as set forth by Reid, Gunn and Bigelow. The early work of Reid showed the method of reduction by manipulation and Gunn left very little for Bigelow by his prior demonstration that the real obstacle to reduction in most cases is the "untorn portion of the capsular ligament," the very same that Bigelow subsequently named the Y ligament and with which readers of Gray were familiar under the name of the ilio-femoral ligament. It is a pity that Dr. Allis should have failed to give Gunn the priority in this matter which is clearly his due. Dr. Allis has, however, added a valuable work to the literature of the subject, and we are glad to see that in those cases of dislocation that can not with ordinary effort be reduced by manipulation, he boldly recommends open incision. With the ordinary aseptic technique in vogue there need be little danger, and as the Roentgen ray may not always be handy, the careful incision may clear up the matter by perfecting the diagnosis.

Don'ts for Consumptives, or the Scientific Management of Pulmonary Tuberculosis. By CHARLES WILSON INGRAHAM, M.D., Binghamton, N. Y., February, 1896. 8vo. Cl., pp. 218.

This book is one that should be placed in the hands of every walking patient suffering from pulmonary tuberculosis, for it shows the pulmonary invalid how he may make and maintain a modern sanatorium of his home, and how recovery may be hastened in many cases. The exact relation of the title to the context of the book may well be questioned for it not only con-

tains an account of what a consumptive should not do but what he should do.

The suggestions are recognized as pertinent and sensible and if carried out by all of the class for whom intended, would greatly diminish the scourge.

ASSOCIATION NEWS.

Section on Neurology and Medical Jurisprudence.

HARTFORD, CONN., April 4, 1896.

To the Editor: The Section of Neurology has arranged for a paper with lantern demonstrations of the medico-legal relations of the X rays. It has been intimated that other similar papers are in course of preparation to be read before other sections. If this is so we shall be very happy to arrange for a combination of these papers at one place and time. If any sectional officers will write me, such arrangement can be made before the program is printed. Or if any one expecting to read a paper on this subject will write me, "a symposium" can be arranged to our mutual benefit. Signed,

T. D. CROTHERS, Chairman of Section.

Rush Monument Committee.

BALTIMORE, March 31, 1896.

The members and delegates of the AMERICAN MEDICAL ASSOCIATION who were constituted members of the Rush Monument Committee at the last session of the ASSOCIATION in Baltimore, are earnestly requested to report to the undersigned the names of contributors and the amounts received from them, not later than Monday, April 20, 1896, in order that the results of the year's work of the Committee may appear in the annual report to be presented at Atlanta on the sixth of May next.

The following Subscriptions to the Rush Monument Fund have been received:

Jan. 6,	Dr. Timothy H. Bishop, New Haven, Conn.	\$10.60
" 6,	Dr. Benj. F. Kittrell, Black Hawk, Miss.	1.00
" 20,	Dr. C. S. Laughlin, Paris, Ill.	1.00
" 20,	Dr. W. A. Buchanan, Paris, Ill.	1.00
" 20,	Dr. W. H. Ten Broeck, Paris, Ill.	1.00
" 20,	Dr. Z. T. Baum, Paris, Ill.	1.00
" 20,	Dr. L. J. Weinstein, Terre Haute, Ind.	1.00
" 20,	Dr. J. P. Worrell, Terre Haute, Ind.	1.00
" 20,	Dr. W. C. Eichelberger, Terre Haute, Ind.	1.00
" 20,	Dr. S. J. Young, Terre Haute, Ind.	1.00
" 20,	Dr. T. A. Mason, Terre Haute, Ind.	1.00
" 20,	Dr. B. E. Swafford, Terre Haute, Ind.	1.00
" 20,	Dr. F. W. Shaley, Terre Haute, Ind.	1.00
" 20,	Dr. Walker Shell, Terre Haute, Ind.50
" 20,	Dr. J. D. Mandeville, Philo, Ill.	1.00

13. Hysterectomy as an Accompaniment to Bilateral Removal of the Appendages, REUBEN PETERSON, Grand Rapids, Mich.
14. Improved Method of Trachelorrhaphy, AUGUSTIN H. GOELET, New York City.
15. Puerperal Infection, its Pathology, Prevention and Treatment, R. R. KIME, Atlanta, Ga. Discussion to be opened by Dr. J. B. S. HOLMES of Atlanta, Ga.
16. Uterine Fibroids When and How to Operate, ALBERT H. TUTTLE, Cambridge, Mass.
17. Gonorrhea in the Puerperium, ALBERT H. BURR, Chicago.
18. Discussion on Vaginal *versus* Abdominal Section for small Tumors and Pus in the Pelvis. To be opened on the Vaginal side by R. S. Sutton of Pittsburg, Pa.; on the Abdominal side by W. E. B. Davis of Birmingham, Ala. Discussion continued by Drs. Joseph Price, J. M. Baldy, F. Henrotin, J. W. Boxée, H. O. Marcy, W. H. Wathen, L. S. McMurtry, R. O. Douglas, N. O. Hardin.

Section on Laryngology and Otology.

1. Chairman's Address, G. V. WOOLEN, Indianapolis, Ind.
2. Adenoids, PRICE BROWN, Toronto, Canada.
3. Some remarks on Adenoid Vegetations in the Vault of the Pharynx. Based upon 100 Operations, G. HUDSON MACKUEN, Philadelphia, Pa.
- Discussion to be opened by ALEXANDER MACCOY, Philadelphia, Pa.
4. Extra-dural Abscess from Mastoid Empyema (Illustrated, Stereopticon), B. ALEXANDER RANDALL, Philadelphia, Pa.
5. Primary Inflammation and Abscess of the Mastoid, report of case, DUNBAR ROY, Atlanta, Ga.
6. Contribution to Cerebral Disease Following Middle Ear Suppuration, M. S. LEDERMAN, New York, N. Y.
7. The Operation of Mastoid Antrotomy for the Cure of Obstinate O. M. P. C., with description and presentation of the Author's Antrotome, H. A. ALBERTON, Brooklyn, N. Y.
- Discussion to be opened by ARTHUR G. HOLMS, Atlanta, Ga.
8. Extirpation of the Larynx, NORVAL J. PIERCE, Chicago, Ill.
9. Surgery of the Nasal Vestibule, with Report of Cases, ROBERT C. MYLES, New York, N. Y.
10. Electrolysis by a Current Controller for the Reduction of Spurs of the Nasal Septum. A Supplementary Report, W. E. CASSELBERRY, Chicago, Ill.
- Discussion to be opened by W. H. DALY, Pittsburg, Pa.
11. Treatment of Chronic Non Suppurative Otitis Media, S. MACCLEN SMITH, Philadelphia, Pa.
12. Some Considerations with regard to the Value of Intratympanic Operations in Deafness, F. H. SHASTID, Galesburg, Ill.
13. Iodin Applications in Eustachian Hypertrophy and Thickened Drumhead, A. J. IRWIN, Mansfield, Ohio.
14. Pneumo- and Phono-Massage Treatment for Deafness Resulting from Suppurative Disease of the Middle Ear, LOUIS J. LAUTENBACH, Philadelphia, Pa.
- Discussion to be opened by E. L. SHURLY, Detroit, Mich.
15. Post Nasal Malignant Tumors, Necessity of Early Diagnosis and Treatment, JAMES H. SHORTER, Macon, Ga.
16. Chronic Abscess at the Base of the Tongue, C. W. RICHARDSON, Washington, D. C.

17. Stricture in the Upper Third of the Trachea successfully treated by Divulsion performed through the Larynx, JOHN O. ROE, Rochester, N. Y.

18. Uncommon Accidents following Operations on the Nose and Throat, MAX THORNER, Cincinnati, Ohio.

Discussion to be opened by E. F. INGALS, Chicago, Ill., and ROBERT C. MYLES, New York.

19. Nasal Hydrorrhea, D. BRADEN KYLE, Philadelphia, Pa.

20. Clinical Notes on Ortho- and Para-chloro-phenol, CONRAD BERENS, Philadelphia, Pa.

21. The Paquelin Cautey, Adapted for Nose and Throat Work, J. MOUNT-BLEYER, New York, N. Y.

22. Electro-cautey Amputation of the Uvula, HANAU W. LOEB, St. Louis, Mo.

Discussion to be opened by JOHN O. ROE, Rochester, N. Y., and JAMES H. SHORTER, Macon, Ga.

23. The Successful Treatment of so-called "Cold in the Head," J. E. SCHADLE, St. Paul, Minn.

24. Keloid Tumors of the External Ear, W. SHEPPEGRELL, New Orleans, La.

25. Treatment of Acute Inflammatory Process of the Labyrinth, J. F. FULTON, St. Paul, Minn.

Section on Cutaneous Medicine and Surgery.

1. Address of Chairman, DR. BULKLEY, New York, On Some of the Newer Remedies Used in Diseases of the Skin.
2. The Occurrence of Lupus in the Wife and Daughter of a Tubercular Subject, J. M. WINFIELD, Brooklyn, N. Y.
3. Excision and Skin Grafting for the Cure of Tubercular Disease of the Skin, M. B. HUTCHINS, Atlanta, Ga.
4. Electrolysis in the Treatment of Lupus Vulgaris, A. RAVOGLI, Cincinnati, Ohio.
5. A Special Form of Dermatitis Due to Crab Bites, T. C. GILCHRIST, Baltimore, Md.
6. Trichorexis Nodosa, G. T. ELLIOT, New York.
7. Leukokeratosis Buccalis and its Treatment, H. C. YARROW, Washington, D. C.
8. On the Treatment of Carbuncle Without the Knife or Caustics, W. E. SHAW, Cincinnati, Ohio.
9. Acetanilid in Skin Diseases, with Report of Cases, A. M. WILSON, Kansas City, Mo.
10. Report of a Case of Chancre of the Lip, E. F. BRUSH, Mt. Vernon, N. Y.
11. A Case of Syphilis Innocently Acquired in Childhood, HENRY A. PULSFORD, East Orange, N. J.
12. Typhoid Fever Complicating the Early Stages of Syphilis, W. D. HAINE, Cincinnati, Ohio.
13. Syphilis Successfully Treated by Hydriatics, ELMER LEE, Chicago.
14. Syphilitic Headaches, their Cure, MERRILL RICKETTS, Cincinnati, Ohio.
15. A Fatal Case of Subcutaneous Gummata, WM. T. GOTTHEIL, New York.
16. Discussion on Syphilis and Marriage, participated in by P. S. CONNER, Cincinnati; EDWIN MARTIN, Philadelphia; J. FOSTER BUSH, Boston; A. RAVOGLI, Cincinnati, and others.
17. Rapid and Successful Treatment of Herpes Zoster, A. H. OHMANN-DUMESNIL, St. Louis, Mo.
18. Further Observations on Urticaria, T. C. GILCHRIST, Baltimore, Md.
19. Discussion on Chronic Ringworm of the Scalp, opened by L. DUNCAN BULKLEY, New York.
20. Institutional Treatment of Scalp Ringworm, CHARLES W. ALLEN, New York.
21. Experience with Ringworm of the Scalp in the New York Skin and Cancer Hospital, HENRY A. PULSFORD, East Orange, N. J.
22. Practical Notes on Ringworm of the Scalp, F. J. LEVINSKY, New York.
23. A Case of Trichophytic Onychomycosis, F. HOLMES BROWN, Grand Rapids, Mich.
24. Facial Baths and Massage in the Treatment of Acne, J. ABBOTT CANTRELL, Philadelphia.

Section on State Medicine.

The Section on State Medicine will meet in Room 15, Kimball House.

OFFICERS OF SECTION.

CHARLES H. SHEPARD, Brooklyn, Chairman.
ELMER LEE, Chicago, Secretary.
Executive Committee—L. H. MONTGOMERY, Chicago; G. W. STONER, Baltimore; C. A. LINDSLEY, New Haven.

TUESDAY, MAY 5.

1. The State Care of Physically Defective Classes, WM. E. WIRT, Cleveland, Ohio.

2. The Sanitary Control of Smallpox, S. L. TEPSON, Wheeling, Va.
3. Preventive Medicine in Apoplexy, EPHRAIM CUTTER, New York City.
4. Heredity as a Social Burden, A. W. WILMARTH, Norristown, Pa.
5. Hygiene versus Drugs, C. F. ULRICH, Wheeling, W. Va.
6. The Prevention of Smallpox, ELMER LEE, Chicago.
7. Drugs vs. Animal Viruses as Prophylactics, REGINALD B. LEACH, Paris, Texas.
8. A Plea for the Domestic Destruction of Garbage, N. E. WORDIN, Bridgeport, Conn.
9. The Welfare of the Community Demands that Marriage Should be Regulated, DANIEL R. BROWER, Chicago.
10. Age and Sex Incidence of Mortality in Michigan, from Diphtheria and Croup, During Twenty-five Years, from 1870 to 1894; a Statistical Study, CRESSY WILBUR, Lansing, Mich.
11. The Prophylaxis of Functional Nervous Diseases, JOHN PUNTON, Kansas City, Mo.
12. A New Treatment of Phthisis, H. W. MITCHELL, New York.
13. Pure Water, FRANK W. EPLEY, New Richmond, Wis.
14. The Evil Results of Overstudy in the Young, THORNTON PARKER, Groveland, Mass.
15. Treatment of Insanity, S. V. CLEVINGER, Chicago.
16. Prevention of Infectious Diseases, J. M. G. CARTER, Waukegan, Ill.
17. The Prophylaxis of Typhoid Fever, JOHN ELIOT WOODBRIDGE, Cleveland, Ohio.

WEDNESDAY, MAY 6.

18. Physicians as Pauperizing Agents; a Review of Some Neglected Points in State Medicine, DOUGLAS H. STEWART, New York. To be read by Dr. Manley.
19. The Turkish Bath, etc., FORBES WINSLOW, London, England.
20. The Therapeutic Action of the Turkish Bath, V. TAGELLSKI, London, England.
21. The Need of Public Baths, CHARLES H. SHEPARD, Brooklyn, N. Y.
22. The Prevention of War and the Promotion of Peace in Relation to State Medicine, EDWARD DAVIES MCDANIEL, Mobile, Ala.
23. Health Boards as Disturbers of the Peace, CHARLES MCINTIRE, Easton, Pa.
24. The Inadequacy of Public Hygiene as a Means of Preventing National Physical Decay, J. H. KELLOGG, Battle Creek, Mich.
25. The Physician's Duty to the General Public, J. W. COKENOWER, Des Moines, Iowa.
26. Health Departments of Large Cities and their Organization, JOHN B. HAMILTON, Chicago.
27. The Methods of Drainage Now Prevailing in Some of Our Eastern Seaboard Municipalities Tending to the Production and Dissemination of Disease, AUGUSTUS P. CLARK, Cambridge, Mass.
28. A Department or a Bureau of Health? Which? S. S. HERRICK, San Francisco.
29. Some Thoughts Relative to a National Department of Public Health, F. E. STEWART, Detroit, Mich.
30. Progress in State Medicine in Pennsylvania, E. O. BARLWELL, Emporium, Pa.
31. Should the State Provide Hospitals for the Treatment of Tubercular Patients? J. S. JENKINS, Tecumseh, Mich.
32. Serum Therapy in Some Diseases, G. T. VAUGHN, P. A. SURGEON, M. H. S., Philadelphia.
33. Suicide: Three Cases, with Remarks, JOHN L. DAVIS, Cincinnati, Ohio.

THURSDAY, MAY 7.

34. State Prevention and Cure of Inebriety, O. EVARTS, College Hill, Ohio.
35. The Abuse of Alcoholic Drinks, its Relation to Public Health and its Prevention, W. BAYARD, St. Johns, New Brunswick.
36. Recent Studies Relating to the Toxic Effect of Alcohol Upon the Nerve Cells, W. H. RILEY, Battle Creek, Mich.
37. The Non-alcoholic Treatment of Consumption, O. G. PLACE, Boulder, Colo.
38. Hospital Management Without the Therapeutic Use of Alcohol, SARAH HACKETT STEVENSON, Chicago.
39. Twenty-one Years' Experience in the Non-alcoholic Treatment of Disease, J. H. KELLOGG, Battle Creek, Mich.
40. What Constitutes True Clinical Experience in Medical Practice and its Relations to the Public Health, N. S. DAVIS, Chicago.
41. The Evolution of Medical Opinion as to Alcohol and Other Narcotics, I. N. QUIMBY, Jersey City, N. J.

42. The Proposed Permanent Badge for the AMERICAN MEDICAL ASSOCIATION, R. FRENCH STONE, Indianapolis, Ind.
43. Tuberculosis, Infection from Food, CHARLES E. WINSLOW, Los Angeles, Cal.
44. Modern Respiratory Advantages, W. T. ENGLISH, Pittsburgh, Pa.

Papers have also been promised by the following: T. D. Crothers, Hartford, Conn.; A. B. Judson, New York; C. H. Hughes, St. Louis, Mo.; G. F. Cook, Oxford, Ohio; G. E. Martin, Carthage, S. Dakota; Charles S. Sheldon, Madison, Wis.

Section on Dental and Oral Surgery.

1. Chairman's Address, R. R. ANDREWS, Cambridge, Mass.
2. A Few Causes of Failures in the Dental and Medical Professions, B. B. SMITH, Pensacola, Fla.
3. Modern Methods of Treating the Antrum of Highmore, W. X. SUDDUTH, Chicago, Ill.
4. Further Investigations Upon the Antrum, M. H. FLETCHER, Cincinnati, Ohio.
5. Pyorrhea Alveolaris, EUGENE S. TALBOT, Chicago.
6. Articulation, W. E. WALKER, Pass Christian, Miss.
7. Cataphoresis, H. W. GILLET, Newport, R. I.
8. The Technique and Pathology of the Peridental Membrane, VIDA A. LATHAM, Chicago, Ill.

SOCIETY NEWS.

Nebraska State Medical Society.—A meeting of this society will be held in the Federal Building, at Lincoln, Neb., on May 19, 20 and 21, beginning Tuesday afternoon, May 19.

The Chicago Medical Society at its annual meeting held April 6, elected the following officers; Harold N. Moyer, M.D., President; Fernand Henrotin, M.D., First Vice-President; Arthur D. Bevan, M.D., Second Vice-President; Junius C. Hoag, M.D., Secretary; Arthur R. Reynolds, M.D., Treasurer; Edmund J. Doering, M.D., Chairman of Publication Committee; D. W. Graham, M.D., Chairman Committee on Library. Delegates were elected to the AMERICAN MEDICAL ASSOCIATION. The annual address by the retiring President, Dr. L. L. McArthur, was an interesting one, on the technique of Surgical Operations on the Kidney. He advocated the transverse incision.

The Tennessee State Medical Society, as already announced in the JOURNAL, will meet in its Sixty-third annual session in Chattanooga, Tenn., April 14, and continue in session for three days. A rate of one and one-third fare for the round trip over all the railroads in the State will be given to those in attendance. The hotels will all give a reduction in rates of 25 per cent. The place of meeting has been secured, and is all that could be wished for. The local profession, or rather the Chattanooga Medical Society, will banquet those in attendance one evening during the meeting.

Iowa State Medical Society.—The forty-fifth annual meeting of the Iowa State Medical Society will be held in Des Moines April 15, 16 and 17, 1896. Delegates to the AMERICAN MEDICAL ASSOCIATION will be elected at this meeting. Railway rates of a fare and one-third have been granted. The route selected is the Chicago & Northwestern; train will leave Council Bluffs May 2, 5:25 P.M., and Des Moines 9 P.M., arriving in Chicago next morning at 7:45, and leave at noon on the JOURNAL special train via Big Four road, Queen & Crescent and Southern Railways, to Atlanta without change of cars, arriving Monday afternoon, May 4. As heretofore announced, the JOURNAL special train will leave Chicago 12 M., Sunday, May 3; Indianapolis, 6 P.M.; Cincinnati, 10 P.M., and arrive in Atlanta 3:10 P.M., Monday.

The Second International Congress of Gynecology and Obstetrics.—The second meeting of this Congress will be held in September, 1896, at Geneva, Switzerland, in the halls of the University. Dr. Betrix is the General Secretary for gynecology, Dr. Cordes for obstetrics, while Dr. Boucart is the General Treasurer for both.

In the Section for Gynecology the following is the official program: 1. Treatment of Pelvic Suppuration—Reporters: Dr. Bouilly, Paris; Dr. Kelly, Baltimore; Dr. Zweifel, Leipzig. 2. Surgical Treatment of Uterine Retro-deviations—Reporters: Dr. Kustner, Breslau; Dr. Pozzi, Paris; Dr. Polk, New York. 3. What Method of Closing the Abdomen Presents the Best Guarantee against Abscesses, Eventrations and Hernias?—Reporters: Dr. Granville-Bantock, London; Dr. La Torre, Rome.

In the Section for Obstetrics: 1. Relative Frequency and Most Common Forms of Pelvic Contractions in Different Races, Groups of Countries or Continents—Reporters: Dr. Fancourt Barnes, London; Dr. Dohrn, Königsberg; Dr. Fochier, Lyons; Dr. Kufferath, Brussels; Dr. Jentzer, Geneva; Dr. Lusk, New York; Dr. Rein, St. Petersburg; Dr. Pawlick, Prague; Dr. Pastalozza, Pavia; Dr. Traub, Leyden. 2. Treatment of Eclampsia—Reporters: Dr. Charles, Brussels; Dr. Charpentier, Paris; Dr. Halbertsma, Utrecht; Dr. Loehlein, Giessen; Dr. Mangiagalli, Milan; Dr. Parvin, Philadelphia; Dr. Smyly, Dublin.

"As indicated by the number and choice of reporters, the Committee, desirous of provoking upon certain questions, investigations and debates as general as possible, has endeavored to present the opinions of the principal schools for discussion, and it is hoped by the Committee that members of the profession engaged in this specialty will attend in large numbers and take part in its discussions or read original communications. Switzerland has always extended a cordial welcome to Congresses held in that country, and this may be taken as a guarantee that the reception which will be given will be worthy of its traditional hospitality. The Committee of Organization will make all preparations that members of the Congress and their families may be assisted in combining their journey to Geneva with other excursions in different parts of Switzerland. The regulations are briefly these: The founders and permanent or life members pay a single initiation fee of 300 francs, which absolves them from the payment of any future dues. Members for one session only pay a fee of 30 francs, upon the receipt of which they will receive a card of membership to the Congress, entitling them to all privileges during that session, as well as a copy of the Proceedings of the Transactions of the Congress. Those desirous of taking part in the discussions are requested to inform the Secretary before the fifth day of July, 1896, stating definitely the questions they desire to discuss."

Association of Military Surgeons of the United States.—Lieut. Colonel Eustathius Chancellor, Medical Director N. G. Mo., Secretary of the Association has announced the program for the sixth annual meeting to be held in Philadelphia, Pa., May 12, 13 and 14, 1896. The indications promise a successful meeting. The presence of many distinguished representatives from the military services and of a large gubernatorial detail from nearly every State in the union has been assured. Headquarters will be established at the Hotel Walton, where the regular business of the sessions will begin at 3 p.m., of Tuesday, May 12. The morning session of Tuesday will be held at the Broad Street Theater at 10 o'clock where addresses will be made by Governor Hastings, Mayor Warwick, General Snowden, Dr. Da Costa, and Dr. Louis W. Read, President of the Association. In the evening there will be a reception at the Hotel Walton. On the morning and afternoon of Wednesday the Association will be the guest of the University of Pennsylvania, with luncheon at the Houston Club. On Wednesday and Thursday evenings receptions will be given by two of the prominent military organizations of Philadelphia; on Wednesday evening a special reception to the medical officers and ladies at the Hotel Walton by the Citizen's Committee; and on Thursday a noonday luncheon tendered by Mr. Wm. S. Saunders at the Art Club. A committee of ladies will look after the welfare of all ladies in attendance on the occasion. Members will wear undress uniform during the day: full uniform with side arms in the evening.

The following papers have been promised for the meeting:

The Physiology of Bathing and Swimming, Surgeon H. G. Beyer, U. S. N.; The Emergency Ration, Captain C. E. Woodruff, Ass't Surgeon, U. S. A.; Experiments with Emergency Ration: Tetanus Resulting from Powder Burns, Captain L. A. La Garde, Ass't Surgeon, U. S. A.; The Effects of Cannon Firing and Explosion on the Ear, Dr. Samuel Sexton, New

York City: Instruction of the Hospital Corps, U. S. Army, Colonel C. H. Alden, Ass't Surgeon-Gen'l, U. S. A.; The Better Type of Medical Officer, Lieut.-Col. A. A. Woodhull, Deputy Surgeon-Gen'l, U. S. A.; A New Bullet-Forceps, Colonel N. Senn, Surgeon-Gen'l, Ill. N. G.; The Annual Encampment, and What it Teaches the Surgeon of the National Guard, Captain J. J. Erwin, Ass't Surgeon, O. N. G.; The Vitality of the Cholera Spirillum in its Relation to Certain Fruit Acids, Passed Ass't Surgeon T. C. Craig, U. S. N.; Is there a Necessity for Differences Between the Standards of Physical Efficiency in the Regular Army and the National Guard, Lieut. Col. Chas. R. Greenleaf, Deputy Surgeon-Gen'l, U. S. A.; What is the Most Practicable Plan of Sanitary Organization for the United States Army? Major J. Van R. Hoff, Surgeon, U. S. A.; The Effects of the New Gun in Field Service, General J. D. Griffith, N. G. Mo.; Notes and Comments on the French Field Sanitary Service, and what we may learn from it, Major Valery Havard, Surgeon, U. S. A.; Modern Methods of Sewage Disposal as Applicable to Military Posts, Major A. C. Girard, Surgeon, U. S. A.; Baths, Bathing and Swimming for Soldiers, Lieut. H. L. Chase, Ass't Surgeon, Mass. V. M.; The Illustrated Travois, Major W. C. Shannon, Surgeon, U. S. A.; Some Thoughts on Wheeled Vehicles for the Transport of Wounded, Major Geo. W. Adair, Surgeon, U. S. A.; What Standard of Visual Acuity should be Required of the Enlisted Men of Our Military Services? Capt. J. M. Banister, Ass't Surgeon, U. S. A.; Methods of Caring for Wounded in Field and Hospital of the Chinese and Japanese Armies, C. U. Gravatt, Surgeon, U. S. N.; Synopsis of a Report on the Medico-Military Arrangements of the Japanese Army in the Field, 1894 and 1895, made to the Director-General, British Army Medical Department, by Surgeon Col. W. Taylor, Army Medical Staff, presented by Colonel Dallas Bache, Ass't Surgeon-Gen'l, U. S. A.; Problems in Medical Administration, with Solutions; accompanied by Suggestions as to the Application of this Method to the Instruction of the Medical Officers of the National Guard, Presented by Colonel Dallas Bache, Ass't Surgeon-Gen'l, U. S. A.; The Epidemiological Features of the Late Epidemics of Plague in China and Cholera in Japan, Passed Ass't Surgeon W. F. Arnold, U. S. N.; Recent Advances in Anthropology Applied to the Physical Examination of Recruits, Major P. F. Harvey, Surgeon U. S. A.; A General Consideration of Athletics: their Value in the Training of Soldiers, Lieut. W. A. Brooks, Jr., Ass't Surgeon, Mass. V. M.; Outlines of the Sanitary Organization of the Army of Denmark, Major John Van Rensselaer Hoff, Surgeon, U. S. A.; Coöperation in Public Sanitation, Surgeon J. C. Wise U. S. N.

The Therapeutic Effect of Anti-phthisin.—In November, 1895, the Parish Medical Society of New Orleans, La., appointed a commission for the investigation and a public test of anti-phthisin, as to its value in tuberculosis, to be made in the Charity Hospital of New Orleans. The commission consisted of the following members: Dr. Edmond Souchon, President; Dr. A. J. Bloch, Secretary; Dr. J. D. Bloom, House Physician, Charity Hospital; Prof. John Elliott, Prof. R. Matas, Prof. F. W. Parham, Dr. F. Loeher, Dr. Charles Chassaignac, Dr. John H. Bemis, Dr. Joseph Holt, Dr. H. L. Lewis, Dr. P. E. Archinard, Dr. O. P. Pothier, Dr. McShane, Dr. C. J. Lanfried. The treatment of cases began November 27, and its final report was presented to the Parish Medical Society at its regular meeting, March 28, 1896. The report is voluminous, and will be published in full. The following are the conclusions in surgical cases:

"A consideration of the three improved cases would certainly lead us to believe that antiphthisin has decided value, and we should commend its careful tentative employment in such cases, in conjunction with general measures and the usual appropriate surgical operative treatment. The glandular case we consider especially encouraging. This case would seem to have required a most serious operation for the removal of the gland, with great uncertainty of ultimate benefit. The improvement under antiphthisin treatment would alone justify us in ascertaining that we have in this remedy a most valuable aid in the management of such cases. We beg to call attention in this connection to the case of Dr. Ambler of Ohio, reported recently in the *New York Medical Record*, as confirmatory evidence of the value of antiphthisin in glandular tuberculosis. The hypodermic employment of the remedy

would seem to be especially advantageous if administered under careful aseptic precautions."

Conclusions in medical cases: 1. In nearly every case the area of lung involved decreased, if it did not clear up entirely. 2. Auscultation bore out the results of percussion, vesicular respiration replacing, in a greater or less degree, morbid breath-sounds. In those cases which were classed as cured, the departure from health being only such as is due to the results of every continued pneumonic process. 3. Secretion was diminished even in the cases marked only improved, and entirely absent in others. 4. Bacteriologic reports in most of the cases bore out the results obtained in physical and other examinations. 5. The general condition of the patients improved in the large majority of cases, even in those whose physical examination did not show any great improvement. 6. The use of the remedy was not attended with any danger to the patient. 7. Finally, antiphthisin does seem to have *curative*, and not simply palliative qualities.

The Wayne County (Mich.) Medical Society held its weekly meeting March 26, at which meeting Dr. Wm. H. Humiston, of Cleveland, Ohio, read a paper on "Some Practical Points in Gynecology." The Doctor eulogized the position and work of the Wayne County Medical Society, and showed where the Society could be of material aid in helping to pass a law by which we as a State would be rid of the quacks, and cited the Cleveland Medical Society as an example. He said he hoped to see our Society of 150 members reach a membership of 300 in another year. He also alluded to the "Detroit Notes" appearing in the AMERICAN MEDICAL ASSOCIATION JOURNAL, which he said was very commendable, as it kept the profession of our city in touch with the profession outside: that it fostered a professional feeling and was a factor in building up the JOURNAL and the AMERICAN MEDICAL ASSOCIATION. The Doctor explained that his paper was for the general practitioner and not for the specialist. He started out with the mode of examination, and what one could learn by manual manipulation, described the sound as a means by which the uterus could be placed or its size determined, and stated that there were none of his senior class but what could determine from digital examination the position and size of the uterus, and said that there was no better way of replacing a retroflexed uterus than by the knee elbow position. The sound and applicator were dangerous instruments to use within and about the uterus, as he had known a number of instances where inflammation had been started, where old troubles had been made active, and the patient placed in quite a precarious condition. The Doctor also spoke of the preparation of patients for operations, especially for celiotomy. He found a considerable number of patients who passed a diminished quantity of urine with a high specific gravity, and said that he made it a routine practice to give all patients before operating a glass of hot water before each meal and at bedtime: that by this means his patients after operation did not suffer from thirst as they were wont to do before resorting to this plan. As to the anesthetic, he left the choice to his anesthetizer.

Dr. C. Henri Leonard, in opening the discussion, said that he was glad to meet an operative gynecologist who was so conservative. The Doctor took issue with the essayist on the danger that might be brought about by the use of the sound and applicator, and said that he could readily see that in the hands of the inexperienced it might and could do damage, but where a reasonable amount of dexterity in manipulations was used by competent men, he did not see the possibility of any damage being done, especially where instruments were kept clean. He himself used lots of soap and water on his hands and instruments, and no bichlorid nor carbolic acid, and had yet to have his first death from any manipulations or operations that he had instituted, and this record in the practice of this specialty for nearly twenty years is not only gratifying, but convincing that his treatments are on the right lines.

Dr. J. H. Carstens said that he was practicing and advocating the same as the writer of the paper, as set down in his essay; that he believed that we could do a great deal by reaching abscesses through the vault of the vagina, evacuating them and draining them, and then when need be, after the acute trouble was over, to resort to radical means to extirpate the

diseased parts. The Doctor also said that he had time and time again opened the abdominal cavity, extirpated one ovary, and found the other partially diseased; that he could excise portions of it and save a part; that he had had several cases where he resorted to these procedures and had had the satisfaction of having his patients menstruate at regular periods and without pain.

Dr. W. H. Longyear agreed with the writer of the paper, and could see where the suggestion of giving abundance of hot water several days before operations upon the pelvic and abdominal organs, would prevent them from having the extreme thirst that we so often have our patients troubled with after these operations. He differed with Dr. Leonard in the conservative treatment of inflammatory diseases of the pelvis, and said that we ought to resort to surgery in the earlier stages and more often than we sometimes do.

Drs. James Sampson, G. R. Cruikshank, J. C. Asbaugh, of Windsor, Ontario, and Drs. G. A. Kirker, K. Gunsolus, O. P. Eaton and W. R. Brand, of Detroit, spoke upon the merits of the paper.

Dr. Wm. H. Humiston exhibited two ovaries from a patient whom he had operated on, which showed chronic degeneration and which contained several small abscesses. They were about the size of an orange, and the patient gave the history of repeated abortions, which were brought on by her own hands. The uterus was twice its normal size, and retroflexed. The Doctor placed it in position by ventral fixation and closed the abdominal wound. The operation was made at the Woman's Hospital, this city. Dr. J. F. Bennett gave the history of the patient whom the Doctor had operated on, who, among the other signs and symptoms that these patients always have, had a continual show of flow the last three months which could not be controlled by intrauterine applications of ergot, etc.

PUBLIC HEALTH.

Improvements in the Drinking Water of Paris.—Fifty-nine communes of suburban Paris have had nothing for drinking water but the water from the Seine, taken below the city, until last January. This is now changed, and the water is all drawn from the river above the city, filtered and delivered to three reservoirs, from whence it is distributed, and considered "quite satisfactory."

To Prevent Epidemics in Arkansas.—According to a law passed in 1895, whenever the health of the citizens of Arkansas is threatened by the prevalence of any epidemic or contagious disease in that or any adjoining State, and in the judgment of the Governor of Arkansas, the public safety demands action on the part of the State Board of Health, the Governor shall call the attention of the Board to the facts and order them to take such action as the public safety of the citizens demands to prevent the spread of such epidemic or contagious disease.

Typhoid Fever Caused by River Ice.—The *Medical Press and Circular* states that there has heretofore been published, in that and other journals, an abstract of the report of the Paris municipal analyst, which revealed the fact that much of the ice served out in clubs and restaurants is of inconceivably filthy origin and laden with nameless abominations. It is now stated that the military officers at Rennes have suffered from a typhoid epidemic which has been traced to the ice which was used to cool the champagne at a banquet. The ice had been taken from the neighboring river at a point where the town sewers empty themselves.

Mortality in New York City in 1895. There were in 1895, 43,420 deaths, with an average annual rate of 23.11 per 1,000 in an estimated population at July 1, of 1,879,195. The census population of April, 1895, was 1,851,060. The births numbered 53,731, marriages 20,612 and still-births 3,372; these three items are all regarded as incomplete. Deaths under five years 18,221, of which the males were 9,782 and females 8,439. Deaths under one year 11,267; males 6,186, females, 5,081. Deaths among the colored 1,100. By infectious diseases there were deaths by diphtheria 1,634, smallpox 342, measles 793, scarlet fever 468, typhoid fever 322, mumps 10. The number of

reported cases of diphtheria and croup was 10,353, measles 8,203, scarlet fever 3,808, typhoid fever, 965 and smallpox 41. Numerous as were the reported cases of measles, there was a decline from the reported cases in 1894, while the proportion of deaths to reported cases was much heavier. The mortality by phthisis at 5,205 was heavier than in 1894, when the white plague carried off 4,658.

Public Works in Italian Cities. The last few years have seen many sanitary improvements in the chief cities of Italy. Rome has changed much and has not grown more beautiful; although the new quarter on Monte Testaccio has had a regular "boom," if such a term can be applied to any part of the Eternal City. The water supply is abundant, many new sewers have been built and also some important works to regulate the Tiber and prevent inundations. A hundred million francs have been devoted to building new sewers in Naples since the cholera epidemic of 1884, demolishing unsanitary buildings and improving others, with the introduction of an abundant water supply and the opening of many streets and public squares. Florence has also opened many new streets and squares, while Palermo has spent forty-four millions of francs in introducing a new water supply and sewer system.—*Journal d'Hygiène*, March 12.

Higher Grades of Antitoxin for Diphtheria.—According to a circular of information recently issued by the New York City Board of Health, after diligent experimentation for a stronger serum against diphtheria, three grades of an extra-potent antitoxin has been produced at the laboratory of that Board. While the serum prepared by Behring and others, and designated by them as Nos. 1, 2 and 3, contain respectively 60, 100 and 150 antitoxin units to each cubic centimeter, the New York Board is now ready to supply what it indicates as its No. 4, having a strength of 200 antitoxin units to the cubic centimeter, No. 5 representing 300 units, and No. 6, 400 units. In using these it will be necessary, of course, to diminish the size of injections in accordance with the added potency of the new preparations; No. 4 having one-half the dosage of No. 2, No. 5 one-half that of No. 3, and No. 6 about one-third of that of No. 3. The price charged per phial for No. 4 is \$1.25; for No. 5 is \$2.00, and for No. 6 is \$3.00. The Behring imported serum also comes in an extra-potent strength, which approximates a concentration of five times the former standard, which is spoken of as the one hundred fold serum. The new variety is called the five hundred fold serum. The old form, as well as the new, is still imported. This concentrated serum is preferable for immunizing purposes as an injection of half a cubic centimeter, about eight minims, of a five hundred fold serum suffices for inoculation before infection. With such a small quantity of serum, local secondary symptoms have not been observed. This extra-potent serum is not prepared from serum of lower activity by a process of concentration, but is obtained direct from the animal body.

Drainage and Plumbing Laws in the Iowa Board of Health. The legislatures of three States, Iowa, Ohio and New Jersey, are engaged upon bills whose intent is the protection of the people's health from injury by bad plumbing. The *Sanitary Plumber* says of the Iowa bill: "This proposed enactment, in its first section, makes it unlawful for master or journeymen plumbers to follow the trade without having first obtained a license. The second clause provides for an examination, under authority of the Board of Health, of the applicant for a license; and section third makes provision for the creation of a Board of Examiners, consisting of the chairman of the Board of Health, a member of the Board of Public Works, and a practical plumber. From May 1, for one year, the sum of \$5 per day for actual service being each member's remuneration. Section four defines the duties, the scope of examination of candidates (practical knowledge of plumbing, house drainage and plumbing ventilation), the fees for licenses, and the licenses so issued being valid all

over the State. The fifth section provides for the appointment in towns and cities of inspectors of plumbing who shall be practical plumbers, and who shall inspect all plumbing work for which permits must be issued. Section six makes it mandatory on Boards of Health in towns where there is a sewerage and water service to formulate a code of rules, and require the filing and approval of plans for work in relation to plumbing, both new work and repairs, before such work can be commenced. The seventh section defines the violation of the statute to be a misdemeanor, the penalty being by a fine and by the revocation of the license. In connection with the movement it should be stated that it had its origin in the desire of master plumbers to elevate the standard of plumbing work in the State but strangely enough the measure is denounced by the press as an effort to create State Boards at the expense of the taxpayers. It is expected, however, that it will become a law."

Vital Statistics for New York State in January, 1896.—The last *Bulletin* of the Board of Health of the State of New York contains the following bills of mortality: There were 10,176 deaths reported during January, and an estimated death rate of 18.50, there having been an average daily mortality of 328, against one of 305 in December, and of 354 in January, 1895. Compared with the preceding month the relative infant and zymotic mortality was the same; there was an increase in mortality from scarlet fever, measles and cerebro-spinal meningitis, and a small decrease from typhoid fever and diphtheria. Compared with January, 1895, there were considerably more deaths from scarlet fever, measles and typhoid fever, that from zymotic diseases being about the same. The increased mortality is over all parts of the State, that from scarlet fever, measles and cerebro-spinal meningitis being limited to the maritime district, the decrease in typhoid fever and diphtheria being general. Scarlet fever was reported from 46 localities in various parts of the State, against 43 in December; diphtheria was reported from 32 localities, the same as in December; typhoid fever from 22 localities, against 34 in December. One death occurred from smallpox, in Brooklyn. Consumption caused 100 more deaths than in December, but 100 fewer than in January of last year. Acute respiratory diseases caused 2,000 deaths, an increase of 250 over December, but 570 less than in January, 1895, and less than in this month for five years. There were 687 reported deaths from diseases of the urinary system, which is an unusual number; other local diseases caused about the same mortality as in December. The large increase in mortality which for several years has been reported in January over December, due to grip, has not occurred and the usual annual recurrence of grip which appears to have set in during December has been far milder than any of the series, not more than 500 deaths being attributable to it this month. There has been a remarkable epidemic of jaundice in the Hudson Valley district, and the reports of death from jaundice elsewhere in the State indicate its probably more wide-spread distribution. The average mean temperature for the month was 4 degrees below the normal, with wind more northerly than usual, of moderate average velocity, and a deficiency in the precipitation (rain or snow fall).

Typhoid Fever at Wilmington, N. C.—The last *Bulletin* of the North Carolina Board of Health has an instructive account of a sequence of typhoid fever cases, due to the use of drinking water polluted with sewage. In the latter part of last November a social gathering of young people, chiefly collegians and their friends, met in an assembly hall. A part at least of the drinking water supplied by the custodian of the hall, was obtained from a polluted source, and as a consequence several cases of typhoid fever, with two fatalities, occurred. The following are some of the significant facts recounted by the *Bulletin*, in relation to these cases: "There are only two sources from which the water supply might have come—the river at the

dock, or the well at Haar's store. But there is no reason to suppose that Haar's well was infected as it is used by his household and quite a number of small stores in the neighborhood, and there has been no report of sickness from the persons using it. We submit the report of Dr. Pate, the bacteriologist at Gibson Station, made at the request of Dr. A. H. Harriss, the Superintendent of Health of Wilmington. Four samples were sent to Dr. Pate: 1, water from the dock at half flood; 2, water from Haar's well; 3, water from the hydrant of the city water works; 4, water that had been in the cooler in Germania hall for ten days. Although no typhoid fever germs were found by Dr. Pate, it is to be remarked that the dock water contained large quantities of intestinal bacilli, and these may have been the cause of the fever, and probably were, as it is now claimed and generally admitted, that the common bacillus of the colon under favorable circumstances may aid in the development of the typhoid germ. At any rate the action of the careless janitor was followed by a terrible calamity—the sacrifice of two beautiful young women, the darlings of their respective families, and endangered the lives of four other young people."

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

New Jersey: Newark, January 1 to 31, 1 death.
Tennessee: Memphis, March 21 to 28, 8 cases.
Louisiana: New Orleans, March 21 to 28, 92 cases, 16 deaths;
Shreveport, March 21 to 28, 1 case.
Kentucky: Paducah, March 24 to 31, 1 case.

SMALLPOX—FOREIGN.

Nantes, February 1 to 29, 2 cases.
Dublin, March 14 to 21, 2 cases.
Acapulco, March 15 to 22, 3 cases, 1 death.
Birmingham, March 14 to 21, 1 case.
Buda-Pesth, March 4 to 11, 1 case.
Calcutta, February 15 to 22, 1 death.
Callao, February 16 to March 8, 4 deaths.
Guayaquil, March 13 to 20, 5 deaths.
Madras, February 22 to 28, 3 cases.
Moscow, March 1 to 7, 1 case.
Odessa, March 7 to 14, 6 cases, 2 deaths.
Paris, March 7 to 14, 1 death.
Prague, March 7 to 14, 8 cases.
Rotterdam, March 14 to 21, 1 case.
St. Petersburg, March 7 to 14, 10 cases, 3 deaths.
Trieste, March 7 to 14, 1 case.
Warsaw, March 7 to 14, 6 deaths.

CHOLERA.

Calcutta, February 15 to 22, 58 deaths.

PLAGUE.

Hong Kong, February 15 to 29, 74 deaths.

YELLOW FEVER.

Sagua la Grande, March 13 to 20, 5 cases.

MISCELLANY.

Divorce in Connection with Suicides and Insanity.—An article in the *Idea Libérale* (French), condemning divorce, states that the number of suicides and insane among the divorced or separated is ten times as large as among the married, and from four to seven times as large as among the unmarried.

Physicians' Beards.—The *Nord Médical* replies to an article on this subject by our esteemed contemporary the *Boston Medical Journal*, which concludes that medical men should not wear beards for bacteriologic reasons, acquiescing and adding that they should all be bald also.

New York Coroner.—On March 27, Dr. Theodore K. Tuthill, of New York city, was appointed by Governor Morton to be Coroner, in place of Dr. William O'Meagher, deceased. He is 45 years of age. He has served as pension surgeon during a part of President Arthur's administration and during the whole of Mr. Harrison's term.

Experimental Rachitis.—Gley and Charrin have produced numerous typical cases of rachitis in animals by inoculating the parents with diphtheritic, tuberculous, pyocyanic and syphilitic toxins, followed by the characteristic curvature of the bones, atrophy, stunted growth, enormous epiphyses, etc., in the offspring.—*Gazette Méd. de Paris*, March 7.

When Will the British Medical Association Visit Canada?—The Montreal Branch of the British Medical Association have invited the Association to meet in Montreal this year. This invitation can not be accepted, as arrangements have already been made to meet in Carlisle, but it is probable that the Medical Association will before long follow the example of the British Association for the Advancement of Science and hold a meeting in Canada.

An Accurate Diagnosis.—He was an only son, a medical student who had a fatal fondness for the fair sex, and as he limped to his usual seat at the breakfast table, his mother inquired of him what was the matter. "Oh," he said, "had a stroke of paralysis last night." "What!" the whole family shouted in terror. "Oh," said the embryo physician, with an exhibition of scorn befitting an American explaining a bit of dry humor to an Englishman, "you see, I just went around to see her last night and her pater objected with a gun, and I came home with this fine case of lead paralysis."

Serum therapeutics in Japan.—Dr. Kitasato is an enthusiast for serum treatment, and has introduced it into Japan with great enthusiasm. His antitoxin is very powerful, nine cubic centimeters being as much as is ever required. The laboratories at Tokio are magnificently equipped, the people are eager to adopt the new treatment, and the percentage of deaths from diphtheria has been reduced from 56 to 8.8 per cent. He prefers the serum from sheep.

The Lyman Prize at the Boston Hospital.—The *Boston Medical and Surgical Journal* states that the "Lyman Prize for the year was awarded to Dr. G. B. Henshaw, of Cambridge, for a paper entitled 'The Treatment of Typhoid Fever by the Typhoid-Thymus Extract.' In announcing the above award it was also stated that the judges had decided 1, that for the future the amount should be awarded to one paper, and that only one prize should be given each year; 2, that the prize would in future be open to competition to any one not more than five years out of the hospital, instead of three years, as in the past."

Study of the Intra-organic Chemic Transformations.—Kaufmann has been studying the respiratory changes, the total excretion of nitrogen and the heat generated in these processes. He used Kjeldahl's process for the determination of the nitrates in the urine, and Hirn's method for the remainder. The man or animal was placed in the air-tight chamber, and the heat and the respiratory changes were determined with great accuracy by tests of the atmosphere before and after. The knowledge thus obtained will be found very useful in future study of these processes, both normal and pathologic. *Gazette Méd. de Paris*, March 7.

Acetylene Gas.—The editor of *Science* writes regarding this substance as follows: "Acetylene gas seems hitherto to have been promoted chiefly with a view to selling stocks and franchises, though we understand the process is not covered by patents. It seems, however, probable that the gas will have important practical applications, which shows once more the practical importance often following chemic research. Acetylene gas is a hydrocarbon compound resulting when water is added to calcic carbon, which is made by fusing lime and carbon in an electric furnace. The only commercial acetylene is now made at Spray, N. C., but it is reported that a furnace is being erected at Niagara Falls, and that large quantities of the gas will soon be manufactured. The advantages of the gas are its brilliant white light, ten to twenty times as great as coal

gas, its portability and (it is claimed) its cheapness. It should be remembered, however, that it is poisonous and, especially in certain compounds, explosive."

Professional Infection.—Dr. Guernonprez, of Lille, was operating on epithelioma of the face, when an abrupt movement turned back his nail. A papilloma developed under the nail soon after, that resisted all treatment for nineteen months. He reports also the case of another physician, now suffering from a cancerous ulceration, who had a habit of scratching his face, and as he often had occasion to treat cancerous troubles, the cause was undoubtedly infection thus received. *Bulletin de l'Académie de Médecine*, March 10.

Dr. L. A. Sayre's Nineteenth Birthday.—Dr. Sayre, of New York city, celebrated February 29 as his nineteenth birthday, although entering upon his 77th year. As the year 1900 has been decreed not to be a leap year, Dr. Sayre's next birthday will not recur until eight years have passed away. Dr. Sayre was the recipient of a shower of congratulations, "receiving messages from England, Germany, France, India, Siam, and from nearly every State in the Union. He received more than one hundred telegrams and cable messages. Several persons sent original poems commenting upon his extreme youth. One of the presents was an oil painting of the old homestead at Madison, N. J., where he was born."

A White Race Native to Tropical Africa.—The *Illustrated Africa* states that a remarkable discovery has been made public by Captain H. D. Laymore, of the Gold Coast constabulary. There is a region beyond the Koranzas to the northeast that is yet unexplored by white men, but the native caravans are constantly passing through the district, which is declared by those who have visited it to be inhabited by a race of white men living in caves. All accounts agree that these cave-dwellers have light hair and blue eyes, and, according to a Mohammedan priest and hadji who had seen them, they are a strong and fearless, but exclusive race, and do all in their power to prevent strangers from passing through their territory.

Pneumococcus Abscess of the Ovary.—Etheridge, *American Journal of the Medical Sciences*, April, 1896, reports three cases of abscess of the ovary due to the pneumococcus. The author has not been able to find any report of ovarian inflammation due to this microorganism. Clinically the cases did not seem to present any special or peculiar conditions. None was preceded by lobar pneumonia as shown by the histories. The striking condition was the tenacious, viscid character of the pus in one of the cases. Etheridge mentions the following as the possible routes of invasion: *a*, the genital passages; *b*, the intestines; *c*, the general circulation. In two of the cases the abscess wall contained "luteal cells," which is interpreted as indicating a corpus luteum as the starting point of infection of the ovary.

Necessity of a Revision of the Supposed Streptococcus Throat Troubles. Widal and Bezancon announce that they have been investigating this subject, with care, and they are convinced that streptococci are always present in healthy mouths and throats. They found them even in the depths of healthy tonsils and they can not be considered an evidence of pathologic conditions. They also isolated and examined 122 specimens of streptococci to find if there were any differences between those found in normal and diseased conditions. They found none. They assert one fact of importance, viz., that bacilli to be virulent must first have penetrated into the tissues. Streptococci found in the mouths of smallpox patients, had scarcely any pathogenic effect on animals, while cultures made from the blood and tissues of the same patient were highly virulent. *Bulletin Médical*, March 15.

Statistics of Pneumothorax. Wishing to secure accurate data for a study of this subject, Galliard addressed a circular letter

to the physicians of Paris and other towns in France, begging them to supply him with the following information: The number of patients in their charge January 22, at 10 A.M., suffering from pulmonary tuberculosis. Also the number of cases of simple pneumothorax, hydro- and pyo-pneumothorax at that same hour. He received 282 replies to his appeal. The total was as follows: 3,415 tuberculous patients, (2,253 men and 1,162 women), 35 with unilateral pneumothorax and 1 bilateral. Of these, 19 were simple pneumothorax, 9 hydro-pneumothorax, 4 pyo-pneumothorax and 3 pneumothorax without vomiting. There was only one case among 283 children. Biarch has kept a record of all cases of this kind in three hospitals in Vienna for twenty-four years, amounting to 433 among the 58,741 tuberculous patients.—*Gazette Méd. de Paris*, March 14.

The Fauna of Cadavers.—M. Mégnin, who has been for some years associated with Brouardel in his medico-legal studies, presents in the form of a monograph (*La Faune des Cadavres*, Paris, reviewed in *British Medical Journal*, March 21) the results of his studies of the biology of the insects found in dead bodies. He shows that it is now possible to determine in an exact manner the time of death of an individual by an examination of the cadaver and of the successive generations of insects found inhabiting it. He has demonstrated that these successive inhabitants always arrive in the same order from the time of death to that of complete disintegration. This period he divides into eight stages, each characterized by a typical denizen. This fact he explains thus: As decomposition proceeds, there is a regular sequence of bacteria. The odor evolved he supposes is characteristic for each successive stage, and these odors serve to attract the particular fauna diagnostic of each of the eight stages. The importance of these observations from a medico-legal standpoint can not be overestimated. M. Mégnin shows by numerous interesting cases that his observations can be used practically.

Large Bequests to Hospitals and Societies in New York.—The will of the late George Bliss, of New York city, partner of Governor Morton, includes the following charitable bequests: Yale University, to be used at the discretion of the president of the institution, \$50,000; Woman's Hospital of the State of New York, \$20,000; Hospital of the New York Society for the Relief of the Ruptured and Crippled, \$20,000; Manhattan Eye and Ear Hospital, \$10,000; also about \$40,000 more to religious organizations; in all not less than \$140,000. Under the will of Bryan Lawrence, late of New York city, St. Vincent's Hospital will receive \$2,500. St. Joseph's Hospital, St. Frances' Hospital and St. Benedict's Home for Colored Children \$1,000 each. Under the will of Mr. William Moir, the sum of \$5,000 will be donated to the Presbyterian Hospital, and also to the Northern Dispensary of New York, in all about \$60,000 being bestowed upon the charitable institutions belonging to the Presbyterian denomination.

Must Consider all the Heads of Damage.—In the case of Brown vs. Foster, decided Feb. 21, 1896, the appellate division of the supreme court of New York said that the jury, when they rendered a verdict for the plaintiff, resolved in her favor all the questions of fact on the merits; and it was then their duty to give her such a verdict as would compensate her for the injuries she had received by falling on an icy sidewalk in front of defendant's premises, by reason of alleged negligence on the part of defendant. There was no doubt that these injuries, while they were perhaps not permanent, were grave. The rule in such a case, the court says, is that where the jury conclude that the plaintiff is entitled to recover they must, in assessing the damages to be awarded, consider all the heads of damage in respect of which the plaintiff is entitled to compensation. These are the bodily injuries sustained; the pain suffered; the effect on the health of the sufferer, according to its degree and its probable duration; the expenses incidental to an attempt to

effect a cure or to lessen the injury; the pecuniary loss sustained through inability to attend to a business, as to which, again, the injury may be temporary or permanent. If they have taken all of these elements of damage into consideration, and have awarded what they deem a fair and reasonable compensation under the circumstances of the case, a court ought not, unless under very exceptional circumstances, to disturb their verdict. In this case the jury, finding that the plaintiff was entitled to a verdict, gave her one for the amount of her doctor's bill, \$108, and no more, and the court holds it inadequate.

Disciplinary Measures in a County Society.—The New York County Medical Society has, at its last stated meeting, expelled by a unanimous vote one of its members, on the score of unprofessional conduct. The charges against the practitioner are in part that he has been for three years or more the conductor of a "private clinic," which latter he has largely advertised in the newspapers and in other ways, and thereby violated one of the by-laws of the Society. He had been summoned to appear before the Society's Committee on Ethics and answer to the accusations against him, but he had disregarded the mandate, as required by the terms of his membership in the Society. Discipline perforce followed. If the reported conversations, given in the daily press, are true the expelled member will not let the matter rest there, but will without delay call the Society to account in the courts in a suit for damages for defamation of character; and also that the true causes for this act of discipline is rather a matter of personal spite or jealousy, on the part of some neighboring practitioners, than the particular alleged fault that has been brought up against him by the Committee on Ethics.

An Anti-Typhoid Serum.—The *British Medical Journal*, February 29, states that in a paper before the Paris Société de Biologie on February 22, on "the Early Diagnosis of Typhoid Fever by a Bacteriologic Examination of the Stools," M. Chantemesse said that last June he had succeeded in immunizing several horses against the virus of typhoid fever. He had obtained the serum of such strength, that one-fifth of a drop inoculated into a guinea pig twenty-four hours before infection protected it against a dose of typhoid virus fatal to animals not previously injected with the protected serum. It was ascertained, also that injections of the serum produced no injurious effects upon a healthy man. M. Chantemesse stated that he had since employed injections of serum in three cases of typhoid fever. The temperature showed a regular fall from the time the first injection was made, and several days after the commencement of the injections all three patients were quite free from fever, and had commenced to convalesce. M. Chantemesse added that the cases were not yet sufficiently numerous to permit any trustworthy conclusion to be drawn.

Bright Points.—Patient: "Doctor, I'm in a bad way." Dr. Newmethod: "Diet." "I can't sleep." "Diet." "I can't eat." "Diet." "I'm bilious." "Diet." "My hair is turning gray." "Dye it."—*New York World*.

"I hear the Apache Indians have broken out again." "Heavens, how many have they murdered?" "Nobody; they've got the measles."—*Yale Record*.

"You've been hanging around here long enough," remarked the citizens' committee, as it proceeded to give the white caps a taste of their own medicine.—*Detroit Tribune*.

"Father," said Sammy, "the teacher says you ought to take me to an optician's. He says I've got astigmatism." "Got what?" "Astigmatism." "Well, if he don't thrash that out of you," roared Mr. Wipedunks, "I will!"

First Physician: "How is that patient you got \$5,000 out of the liability company for? Able to be out?" Second Physician: "Not yet; I'm going to get my whack out of that \$5,000 first."

Mr. Dolley: "Medical experts say that the uncarbolized kiss is deadly." Miss Flyp: "I'm no coward."

Gastroscopy.—In the *British Medical Journal*, Dr. Rosenheim is quoted as the inventor of a new gastroscope—made for him by Hirschmann of Berlin—which he expects will be suitable in some cases for which other instruments will not suffice. That author in the *Deutsche Medicinische Wochenschrift*, has discussed the position of the cardia and the course of the lowest part of the esophagus. He concludes that the usual position of the cardia in the adult is opposite the twelfth, rarely the eleventh, dorsal vertebra. The anatomic relations are important in respect to the use of the gastroscope. He maintains that where it is impossible to pass a stiff tube into the stomach with the patient in the dorsal position, the difficulty is due to muscular cramp or to the physiologic bend at the esophageal foramen in the diaphragm. By introducing the rigid tube from the right side of the mouth and pressing the point to the left, the lowest part of the esophagus can be most readily passed. A certain gentle pressure may be necessary, and a change in the patient's position from the back to the right side may facilitate it. In a minority of cases with disease involving the cardia, the parts may not be distinctly seen by the gastroscope without an anesthetic. The author then refers chiefly to Mikulicz's investigations into esophagoscopy. This authority used a curved tube in order to overcome the difficulty of passing through the lowest part of the esophagus; he thought that it was impossible to accomplish this with a straight tube. This curve introduces difficulties in respect to the optical arrangements. The author maintains that the optical apparatus should be in the straight line. His observations lead him to say that in nearly 70 per cent. of the cases examined by him a straight gastroscope can be passed into the stomach. Under certain conditions, such as an abnormal curving of the esophagus due to pathologic causes, it may be impossible. A local spraying with cocaine by means of a special apparatus has been tried by the author to overcome the cardiospasm, but with indifferent success. He concludes that with few exceptions it is possible with a straight or slightly curved instrument to get deep enough into the stomach for gastrosopic purposes without an anesthetic and without doing any injury. One gastroscope will not suit all cases, but a straight instrument suffices in by far the majority of cases.

Practical Notes.

Blisters.—Huchard asserts that blisters are a survival of barbarism, or words to that effect. He has observed albuminuria and acute uremia, as also interstitial nephritis, follow the application of a single blister, and strongly deprecates their use, even in pleural troubles.—*Bulletin Médical*, March 15.

Lactic Acid in Ulcerations of the Cornea.—Dolgenkov has secured excellent results in forty cases, most of them chronic, by dropping three or four drops of a 50 per cent. solution of lactic acid into the sore; the inflammation disappears, and the ulceration heals completely.—*W'atch*, No. 29, 1895.

Oxydizing Powers of Organs.—Abelous and Biarnes announce that this power can be measured in an organ by the effect of salicylic aldehyde upon it. The spleen, lungs and liver are pre-eminent; next come the kidneys, suprarenal capsule, pancreas and thyroid glands, while the nerves and muscles scarcely possess it at all. This is contrary to what has generally been accepted.—*Bulletin Médical*, March 11.

Cantharidin Internally Administered in Tubercular Disease.—The *New York Medical Journal* has the following formulas of Dr. J. Frendenberg (*Therapeutische Wochenschrift*) for the exhibition of this drug: Cantharidin 1 part, alcohol 1000 parts, distilled water, 100,000 parts. He directs a teaspoonful, diluted with water, to be taken three or four times a day in cases of cystitis. Solutions of cantharidin are not very stable; consequently if the remedy is to be used for a considerable length of time, as in scrofula and tuberculosis, it is better to order it in pill form according to the following prescription:

Cantharidin, 2 milligrams (0.031 gr.), white bole, 2 grams (30.86 grs.); mix and divide into thirty pills, of which one is to be taken daily, before breakfast.

Adherences between the Peritoneum and the Symphysis discovered in Suprapubic Cystotomy.—At the last meeting of the Soc. de Chir., Paris, Rollet reported three cases of adherences observed between the cul-de-sac of the peritoneum and the pubis, which is so rare that Petersen's and Polaillon's are the only cases on record in France, while it often occurs that the peritoneum descends very low. Some members thought that Rollet might have mistaken the latter for adherences, but in either case surgical interference is not contraindicated.

Treatment of Certain Tumors in the Mouth with Chlorate of Potash.—Dumontpallier recommends this treatment in high terms, as he has been very successful with it in his practice. He applies it, finely pulverized to the tumor, four times a day, and administers it internally also, in a solution of 4 grams to 120 grams of water. He ascribes its beneficial effect to the fact that it passes into the secretions of the salivary glands, and thus keeps the tumor under its influence all the time. This treatment must be continued two or three months and the kidneys must be kept in good order. All sources of irritation from the teeth must be carefully exterminated. Before resorting to the bistoury he urges this treatment to be tried in almost all cases.—*Bulletin Méd.*, March 11.

Hiccough and Other Suffocative Symptoms.—The *Popular Science News* has an annotation to the effect that a means of relieving a certain proportion of such cases has been accidentally found, as follows: "A female patient presented herself at a French hospital for a rebellious hiccough, which had resisted all treatment for four days. She was asked to show the tongue, and it was noticed that with the putting out of the tongue, the hiccough ceased. The same thing has been since tried, and with success in other cases. All that is necessary apparently is to strongly push the tongue out of the mouth and hold it so for a minute or two. It is also suggested now to try the same thing in suffocative cough, as whooping cough, and choking by irrepressible gases."

Family Tendency to Appendicitis.—Many families are known where several members have suffered from appendicitis, and the question is being discussed just now, whether this is due to a congenital malformation, or an arthritic tendency, or to a tendency to parenchymatous gastritis, which is known to be hereditary and Hayem's experience has been that it is an invariable accompaniment of appendicitis. Whatever the cause, a family diathesis of this kind is an indication for prompt intervention at the first symptom of appendicitis, and Faisan considers it sufficient to call for the removal of the appendix even in the mildest cases of trouble. Bouchard noted some time ago that victims of appendicitis were especially those who suffered from gastric troubles. *Gazette Méd. de Paris*, March 7.

Louisville.

UNIVERSITY OF LOUISVILLE. The Medical Department of the University of Louisville held its annual commencement exercises at Macauley's Theater on March 30, the graduating class numbering fifty-nine. Dr. J. M. Bodine, who has been Dean for the past twenty-seven years, presided, the Hon. Jas. S. Pirtle, President of the Board of Trustees, conferred the degrees. The valedictory address was delivered by Dr. Henry Wm. Coleman of West Virginia, and Dr. C. M. Rosser of Texas, delivered the alumni address, his subject being "Doctors and Doctors." Dr. H. A. Cottell delivered the Faculty address, the "Life and Character of the late Professor Edward Rush Palmer, M.D.," being his subject. He prefaced his remarks with the following: "Like a plaint of sorrow after shouts of joy; like the cry of pain that calls the kind physician from the circle of good cheer to the bed of suffering; like an elegy of

blight after sunshine and bright flowers of May time; like the heart-breaking phrases of the funeral march after the bright melodies which have gladdened this festal day, I come with sorrow's solemn theme, and change the scene from gay to grave while your Alma Mater pays tribute to the memory of her most beloved and gifted son. For never in the fifty-nine years of its eventful existence, from among the eminent names upon the professional list, has the University lost a teacher so bright, so eloquent, so original and at the same time so beloved of his pupils as Professor Edward Rush Palmer." After giving many facts relating to Dr. Palmer's life and his ancestors, Dr. Cottell concluded with the following: "I have recited as best I could the incidents in a remarkable life and have attempted to portray in homely sketches the character of a benevolent, forceful and benevolent man. If I have read the lines aright the lessons to be learned from his life are, singleness of purpose, faith in one's self, faith in humanity, and faith in the final triumph of good. Such was the creed that Palmer's life proclaimed, whatever his work might be. He had no sympathy with asceticism, or pessimism, and no patience with hypocrisy or cant. The windows of his soul were thrown wide open to the sun, and Apollo, the god of sunshine, music, poetry and medicine ever held him in fealty if not in worship. His sunny spirit has gone out from the circle of the days and the solemn question, where, with its awful significance, bids us pause once more ere we say farewell. Has it, like gentle Hesperus, but faded away for a season in the many tinted clouds of evening twilight, to shine anon with with fairer luster in the morning sky? Let us have faith to hold it so."

METEOROLOGIC SUMMARY.—The report of the weather bureau for the last month shows many interesting points about the climate of Louisville and vicinity. The maximum temperature was 71, and the minimum 16, the mean being 40. The prevailing winds were southerly. The mean atmospheric pressure 30.107 inches, the maximum velocity of wind 35 miles, direction southwest, date 28th. Total precipitation 4.86 inches, this being exceeded only eight times in the last twenty-four years. Number of clear days 8, number of cloudy days 14, number of partly cloudy days 9.

NORTON INFIRMARY.—The tenth annual report of the John N. Norton Memorial Infirmary has just been issued and shows this worthy institution to be in a splendid condition. It has as a frontispiece a very good picture of the Infirmary, then follows a list of the board of trustees, officers and managers; then a report from the President, The Rt. Rev. T. U. Dudley, Bishop of Kentucky.

DR. BURNSIDE.—Dr. Robert Burnside of Barboursville was stabbed on the evening of March 28, and as a result of his wounds died April 2. Sawyer, the man who stabbed Dr. Burnside, is a desperate character, and his attack upon the Doctor was wholly unwarranted and unexpected. There were no witnesses but a few boys who were too scared to know what to do, and there is little doubt but that the murderer will go scott free.

Cincinnati.

THE MORTALITY REPORT for the week ended Friday, March 27, shows: Diphtheria 2, measles 2, typhoid fever 2, whooping cough 1, other zymotic diseases 2; cancer 1, phthisis pulmonalis 19, other constitutional diseases 7; apoplexy 4, bronchitis 11, convulsions 2, meningitis 6, nephritis 4, pneumonia 20, other local diseases 31. Deaths from developmental diseases 11, from violence 3, under 1 year 22, from 1 to 5 years 29, from all causes 128. Annual rate per 1,000, 19. Deaths during the preceding week, 123; during corresponding week 1895, 146; during corresponding week 1894, 99; during corresponding week 1893, 108.

DR. CHARLES S. MUSCROFT has been appointed a member of the Ohio Penitentiary Board of Managers.

DR. ORPHEUS EVERTS has just published a small poetic volume entitled "Facts and Fancies."

A CASE OF SEVERE EPISTAXIS was admitted to the City Hospital last week which resisted all attempts to stop it for two days.

THE GRADUATING CLASS of the Miami Medical College numbered twenty-six, while the Medical College of Ohio turned out eighty-four, and the Cincinnati College of Medicine and Surgery twenty-four.

THE SUIT against Dr. A. P. Taylor, of Lexington, Ky., for \$6,000 for malpractice, has resulted in a verdict for the defense.

AN EPIDEMIC of cerebro-spinal meningitis is raging at Paintsville, Ky. There are twenty cases and nine deaths reported.

THE ACADEMY OF MEDICINE discussed the subject of expectation in street cars and on the streets. The Women's Civic League are endeavoring to arouse a public sentiment against this filthy habit, and the Academy passed a resolution endorsing their move.

DR. B. F. BEEBE presented to the Academy a case of supposed chylous ascites. The patient, a middle-aged man, locomotive engineer, and of a good history, noticed a swelling on his abdomen about six months ago with no other symptoms. This rapidly increased and on account of the severe dyspnea Dr. Beebe had inserted a trocar into the abdomen and extracted about two gallons of fluid resembling milk. Upon examination this fluid was found to be composed of fat globules finely divided, no flocculi or other ingredients, after standing ten days the fluid decomposed and turned a dirty yellow. The heart and kidneys were normal. At present it is estimated there are two or three gallons of fluid in the abdomen. Emaciation is becoming noticeable.

DR. H. W. BETTMAN presented a case of locomotor ataxia in which the stomach was found to be of normal size but located below the umbilicus and extending down to the floor of the pelvis. This was demonstrated by trans-illumination with the electric light.

DR. JOS. RANSOHOFF presented a case of excision of the shoulder for tubercular disease of the head of the humerus. The incision had been made across the arm instead of parallel to its long axis, and the result was very satisfactory. A case of cyst of the spermatic cord in which the cyst had been removed without rupture was also shown.

DR. W. B. WEAVER presented a case of an infant which had been intubated when nine months old for some dyspnea and cyanosis; relief was at once obtained, and some time after the tube had been removed the child coughed up a piece of tin about half an inch square.

Detroit.

THE DETROIT MEDICAL AND LIBRARY ASSOCIATION at its meeting Monday, March 30, did not have a regular paper, but there were very many pathologic specimens presented, and a number of very interesting cases reported. Dr. Theo. A. McGraw showed the specimen of a case of extrauterine pregnancy of five months, which he had operated on. Dr. F. D. Summers reported a case, and showed specimen of a cyst of Fallopian tube, left side, in a girl past 15 years of age. The history was one of amenorrhea and dysmenorrhea; and only by examining the patient under chloroform was he able to make the diagnosis, which was then quite easy. Dr. Theo. A. McGraw reported another case of double fracture and dislocation of head of humerus, where he attempted to do the McBurney's operation with McBurney's hook, but was unable, made an incision over the head of humerus and found the greater tuberosity of humerus separated; also head of bone fractured and dislocated in the axillary space. This made it impossible to raise it with the above named instrument, and the doctor was obliged to make an incision in the axillary space and extract the head of the bone. Dr. W. R. Parker reported five cases of obstetrics with L. O. P. position in the last few months, two of them being primiparæ.

THE MICHIGAN COLLEGE OF MEDICINE AND SURGERY held its commencement at the Detroit Opera House March 24, at which forty students received their degrees of M.D., of which four were ladies. Dr. L. E. Maire read the address for the faculty.

THE WAYNE COUNTY MEDICAL SOCIETY at its regular meeting Thursday, April 2, had a general discussion on "Medical Legislation."

HEALTH OFFICE REPORT for week ending April 4: Deaths under 5 years 37, total 85. Births, male 57, female 58, total 115. Contagious diseases: Diphtheria, last report 12, new cases 10, recovered 10, died 3, now sick 9; scarlet fever, last report 20, new cases 11, recovered 10, died 2, now sick 19; small-pox, last report none, new cases none, recovered none, died none, now sick none; measles, last report none, new cases 2, recovered none, died none, now sick 2.

HARPER HOSPITAL in its monthly Bulletin for February, 1896, gives the Annual Report for the year ending December, 1895, which, owing to the generosity of many of the business men of the city, is a very pleasing one; moreover, much of the efficiency of the hospital is due to the fact that although the Board of Trustees is largely composed of business men, yet they have left the workings of the hospital almost entirely in the hands of the medical men who are in connection with the hospital. The President of the Board of Trustees in his report mentions the fact that the collections from the earnings of the hospital together with the interest received from the free bed and general endowment funds, exceeded the running expenses of the hospital for 1895. He reported the graduation of fifteen nurses from the Farrand Training School, well equipped for their profession. He also said that the work of the Polyclinic had never been more satisfactory than during the past year, the number of patients treated being 2,365, and prescriptions furnished 7,567. All examinations, treatment and prescriptions were free. The number of patients in the hospital Jan. 1, 1895, was 61, the number admitted during the year was 1,450, making a total of 1,511. Discharged 1,300, died 124, remaining Dec. 31, 1895, 87. The receipts for 1895 amounted to \$42,284.65. The earnings for 1895 were \$37,109.11; the collections turned over to the Treasurer were \$32,059.18. The disbursements for same year amounted to \$42,284.65, which amount did not include the cost of the ambulance barn. The endowment funds of the hospital now are: William Kieft Coyl Free Hospital, \$211,751.40; private free beds, \$86,000; Farrand Training School for Nurses, \$20,000; the Henderson free bed, \$2,500; general endowment, \$58,500. Dr. J. H. Carstens, the Chief of the Medical Board, reported that during the year 1895 there were treated 1,358 different persons, being 81 more patients than were treated in 1894. There were 599 medical patients, 1,093 surgical patients, including 375 gynecologic cases. According to the report of Dr. Sargent, the microscopist, there were 1,198 specimens of urine examined, 110 specimens of sputum, 35 specimens of pathologic material, such as tumors. In each case of diphtheria the diagnosis was confirmed by the growth and microscopic determination of the Klebs-Loeffler bacillus.

Philadelphia.

IRON HYPODERMICALLY GIVEN IN ANEMIA.—At the meeting of the College of Physicians, held April 1, among the papers read was one by the President, Dr. J. M. DaCosta, "On the Hypodermic Use of Iron," in which he referred to his experience with various forms of this agent, since 1874, when he originally used the ammonia citrate in symptomatic anemia. He now uses the citrate of iron and magnesia, in solution in water and finds that it rapidly produces the chalybeate effects upon the blood and is entirely free from local irritation or abscess.

CHRONIC ILLNESS IN A CABIN PASSENGER DEBARS HIM FROM IMMIGRATING.—A second-cabin passenger on the trans-Atlantic steamer *Rhyndland*, because of alleged chronic illness was

debarred from landing by the Commissioner of Immigration, on March 18. The passenger was a man 26 years of age, who was accompanied by his father, an Irish farmer. It is stated that the latter made no comment upon the fitness of the law, by which his son was refused permission to land, but condemned the steamship company for selling the tickets when it must have been cognizant of the provisions of the law. The father expressed his intention of returning with his son by the next steamer. It is said that this is only the second instance of a cabin passenger being debarred from landing at this port. Some years ago an English philanthropist sent over two young girls consigned to a New York Children's Aid Society through whom it was intended to send them to homes somewhere in the west. That case appealed to the supreme court, which sustained the action of the local Board of Charities, which then had supervision of immigration at this port, and which had ordered them to return to England.

EVIDENCES OF MAN'S ANTIQUITY.—At the March meeting of the Contemporary Club, Prof. Edward S. Morse, of Salem, Mass., by invitation delivered an address on the subject, "When did Man first Appear on Earth?" At the beginning, the lecturer stated that it was impossible to declare positively within 100,000 years, how long man had existed on earth. There were marked differences in races of mankind forty or fifty thousand years ago, but we must believe that they had a common origin. There must have been a time when there was a common type. Man has been produced by the convergence of several lines of development the same as in the case of all animals. Whatever age the geologists are willing to ascribe to the tertiaries, the lecturer was disposed to accept as the date of man's appearance upon earth. At the conclusion of Professor Morse's address, Prof. D. G. Brinton stated that few geologists now think the four instances of human remains that were found in the tertiaries, to be genuine. It has come to be believed that man's origin was at a much later time, following the glacial epoch. While man himself is connected with the great chain of organic life, direct ancestry, in Dr. Brinton's opinion, had not been proven. He did not find an absolutely final argument. He had no doubt man began at one place. He further believed that man achieved his high position not by a long slow method, but that he burst into the world in one time, with his faculties and powers greater than any of his parents possessed. He cites Shakespeare and Goethe as illustrations of this exceptional endowment. Darwin himself acknowledged that what was called spontaneous variation was far beyond all his means of investigation. There is some change which occurs in prenatal life which develops the first genius or poet of a century, and it was something of this nature which occurred when man was developed from a lower animal.

VACANCIES IN BERCKLEY STAFF FILLED.—At the meeting of the Department of Charities and Correction, the vacancies in the attending medical staff of the Philadelphia Hospital were finally supplied after a most exciting and lively canvass. Dr. Augustus A. Eshner, a graduate of Jefferson College, was elected to fill the vacancy occasioned by the resignation of Dr. E. L. Vansant, and Dr. Alfred Stengel, a graduate of the University of Pennsylvania, succeeded to Dr. J. M. Andus' position. Dr. H. B. Allyn was elected Registrar, succeeding Dr. J. Chalmers DaCosta, who was advanced to the Surgical Staff. Dr. J. Wharton Sinkler resigned from the Neurological Staff; Dr. Charles H. Burr will probably succeed to the position.

PHILADELPHIA DENTAL COLLEGE. Dr. Henry I. Dorr has resigned from the Philadelphia Dental College and will remove permanently to California on account of his health. Dr. L. Greenbaum has been elected to his chair of Anesthetics and Odontotechnics.

THE HOSPITAL FOR CONTAGIOUS DISEASES. A Committee of the County Medical Society has been appointed to confer with a Committee of the Woman's Health Protective Association in reference to the proposed new hospital for contagious diseases.

DEATH OF THE OLDEST ALUMNUS OF JEFFERSON MEDICAL COLLEGE. Dr. Jacob M. Gemmell, who for some years enjoyed the honor of being the oldest living graduate of Jefferson Medical College died at his home in Philadelphia March 21, in the 86th year of his age. He was born in Alexandria, Virginia, Sept. 24, 1810, and was graduated in medicine in 1831. After practicing for a few years in his native place, he removed to Altoona where he was physician to the Pennsylvania Railroad. Since 1876 he had resided in Philadelphia. For many years he had been a member of the Blair County Medical Society and of the State Medical Society, of both of which he had been President.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from March 28 to April 3, 1896.

First Lieut. Henry C. Fisher, Asst. Surgeon, is relieved from duty at Ft. Yates, N. Dak., and ordered to Plattsburg Bks., N. Y., for duty.
Capt. Adrian S. Polhemus, Asst. Surgeon, will be relieved from duty at Ft. Douglas, Utah, upon the expiration of his present sick leave of absence, and ordered to Ft. Wingate, N. M., for duty.
Capt. Philip G. Wales, Asst. Surgeon, now on duty at Ft. McPherson, Ga., will report in person to the commanding officer, Ft. Monroe, Va., for temporary duty at that post.
Capt. Francis J. Ives, Asst. Surgeon, is relieved from duty at Plattsburg Bks., N. Y., and ordered to St. Francis Bks., Fla., for duty at that station, relieving Major Daniel G. Caldwell, Surgeon.
Major Daniel G. Caldwell, Surgeon, on being relieved from duty at St. Francis Bks., Fla., will report in person to the president of the Army retiring board at Washington Bks., D. C., for examination by the board. By direction of the President.

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the fifteen days ended March 31, 1896.

Surgeon P. H. Bailhache, granted leave of absence for three days, March 30, 1896.
P. A. Surgeon C. E. Banks, to proceed to Baltimore, Md., to inspect un-serviceable property; then to rejoin station at Washington, D. C., March 30, 1896.
P. A. Surgeon C. T. Peckham, granted leave of absence for thirty days, March 26, 1896.
P. A. Surgeon L. L. Williams, granted leave of absence for fifteen days, March 26, 1896.
P. A. Surgeon J. O. Cobb, granted leave of absence for two days, March 25, 1896.
P. A. Surgeon J. B. Stoner, to proceed from Baltimore, Md., to Savannah, Ga., and assume command of Service, March 16, 1896.
Asst. Surgeon Emil Prochazka, to proceed from Detroit, Mich., to Evansville, Ind., for temporary duty; then to rejoin station at Detroit, March 19, 1896.

Change of Address.

Andrews, Jr., B. B., from St. Louis, Mo., to Stella, Neb.
Baird, T. M., from Hot Springs, to Forest City, Ark.
Caldwell, J. R., from 202 Gladys Ave., to Chicago View Hotel (Ashland Ave. & Madison Street), Chicago, Ill.
De Hart, J. N., from 203 Willoughby Ave., to 137 Keap Street, Brooklyn, N. Y.
Hamilton, John B., from 20 Custom House, to 315 Rand McNally Building, Chicago, Ill.
Jeffery, Alicia F., from California Building to 633 Bert Street, Denver, Colo.
Kirkpatrick, O. B., Cherry Fork, Ohio, to 56 Lexington Ave., New York, N. Y.
Musser, C. J., from St. Louis, Mo., to Hampton, Iowa; Mull, Fred, Allendale, Mo.
Owsley, W. T., from Lexington to Glasgow, Ky.
Perdue, E., to Orrick, Mo., from St. Louis, Mo.
Robinson, R. D., Indianapolis, Ind.

The Journal of the American Medical Association

VOL. XXVI.

CHICAGO, ILL., APRIL 18, 1896.

No. 16.

ADDRESS.

THE PATHFINDERS.

Delivered to the Graduated Class of the Barnes Medical College, St. Louis, Mo., March 17, 1896.

BY JAMES T. JELKS, M.D.

Professor of Gynecology and Syphilology in Barnes Medical College, St. Louis, Mo.; formerly Professor of Genito-Urinary Surgery and Venereal Diseases in College of Physicians and Surgeons of Chicago; Ex-President of Arkansas Med. Society; Ex-Secretary Obstetric and Gynecological Section American Medical Association; Member of Chicago Med. Society, Mississippi Valley Medical Society, American Ass'n of Obstetricians and Gynecologists, and Southern Gynecological and Surgical Ass'n, and Ex-chairman of Section on Anatomy and Surgery of American Medical Ass'n.; Consulting Surgeon Mo. P. and I. M. Ry's.

HOT SPRINGS, ARK.

Gentlemen of the Graduated Class:—I have been requested by the faculty of Barnes Medical College to address a few words to you in parting. I feel the importance of the occasion, and if I shall say anything which you can carry home with you and which will enable you to be better physicians or truer men I will have done much. You have passed your final examination for the degree of M.D.; upon this I congratulate you and trust the future may bring to you, all that your mind can picture of success or your heart crave of sympathy.

You have only made a beginning; have simply learned the alphabet of your new life. We have tried to teach you *how* to study; how to use the tools of your new calling; have simply laid the foundation; upon this you must build a superstructure of hay, wood or stubble, or a structure of solid materials which will weather the storms of adverse fate, or come through the fires of criticism unscathed; then I say, your life work is just begun; remember the battle is not necessarily to the swift or the brilliant, but success comes rather to the painstaking, laborious one, who knows no such word as fail, and who is willing and anxious to work, contented, if he does well whatsoever his hands find to do.

Think not there are no more worlds to conquer; that the wonderful strides in the arts and sciences of medicine and surgery during the last twenty years, leaves no field for you to investigate. Some one of you may be an Alexander to lead the hosts of sanitary science along new fields and beside pleasant pastures. Few thought two months since of the possibility of photographing through opaque objects, and yet to-day, the world is familiar with the "X" ray of Roentgen, and its possibilities in medicine and surgery, as they loom up before us, are fairly dazzling. Here is a Pathfinder indeed; and we believe the time is not far distant when we shall see our friends as we talk with them over the telephone, whether they be in the next house, the next town, or as far from us as St. Louis from New York. New worlds are lying out all around us waiting a conqueror who shall show us the way.

"Then be up and doing,
With a heart for any fate;
Still achieving, still pursuing
Learn to labor and to wait."

There are two classes of men in life. The artist who plans, who leads the way, and the artisan who follows and does the work planned for him by the leader. These two comprise the working classes of humanity. Of the first class or

THE PATHFINDERS

I propose to speak a few words to you to-night, hoping thereby so to stimulate you in your work that some one among you may develop as a leader among men.

It is an easy matter for any one to follow the king's highway from place to place. It is comparatively easy for one versed in woodcraft to find his way out of a great forest and into the homes of civilization; or for the mariner with his compass to steer his course over the trackless sea. We can all follow where the Pathfinders lead. That was a beautiful character of Cooper's, "The Pathfinder" or old "Leather Stocking," with his unerring judgment of men and nature; always pushing out beyond the outposts of civilization, whether that was in the forests of New York, along the shores of the northern lakes or on the boundless prairies of the great West! And there are such men in the profession of medicine—leaders whose look is ever forward—and behind whom follow the great mass of the profession; many times ignorant of the hard work and sufferings and triumphs of him who was the pioneer along a rough and rugged road, now smoothed for the easy going of the less laborious ones. I would not have you understand that the work of the artisan is less honorable than that of the artist who plans the beautiful structure. Both are alike praiseworthy; and while it is given to a few to be leaders of men, yet we may all be workers.

"And departing leave behind us
Footprints in the sands of time."

The poetess Ella Wheeler Wilcox has written:

There are two kinds of people on earth to-day,
Just two kinds of people, no more, I say.
Not a sinner and saint for 'tis well understood
The good are half bad, and the bad are half good;
Not the rich and the poor, for to count a man's wealth
You must first know the state of his conscience and health;
Not the humble and proud, for in life's little span,
Who puts on vain airs is not counted a man;
Not the happy and sad, for the swift flying years
Bring each man his laughter and each man his tears.
No, the two kinds of people on earth I mean,
Are the people who *lift* and the people who *lean*.
Wherever you go, you will find the world's masses
Are always divided in just these two classes.
And, oddly enough, you will find, too, I wean,
There is only one lifter to twenty who lean.

The dead level of mediocrity we may all attain; it is the floor upon which we were born and upon which most of us will fret and work out our earthly existence. We are the artisans who do the drudgery of

the world, and I would not complain of mediocrity, for to the many, to the artisans, must the world look for the accomplishment of its vast problem of labor. Though we may belong to this class, let us love our work. If you do not love this profession you have chosen—love it enough to give your life enthusiastically to it, then let me urge you now to give it up, before it is too late, and find something to do which will command all the love and energy of your souls.

Enthusiasm, fanaticism if you will, moves the world. The enthusiasts are the Pathfinders for the world. "Youth without fire leads to an old age without warmth." Then while the warm blood of youth permeates your hearts, plunge headlong into your work. "Whatsoever your hands find to do, do it with all your might," and thus only may you hope to attain to an old age warmed by the thought of a life well spent. He who is without enthusiasm in his calling is a finished being, and is simply waiting for the inevitable, which shall take him over to the great majority.

I do not propose to go over the whole field of medicine and give you an outline of all its leaders, but to call your attention to a few of the men who have led us into the broad fields and green pastures of modern medical knowledge.

It has not been many years since the practice of surgery meant great agony to the patient. He had to be held, while the sharp steel severed nerve and muscle and bone. Think of the awful suffering of the wounded who had to have an extremity amputated, or a dislocated one restored to place! Think of the dreadful agony of maternity! And all these pains alleviated by a few whiffs of chloroform or ether!

My friend, Dr. Ghent, of Texas, tells of a woman who was a patient of his under these trying circumstances for her fifteenth time. He administered chloroform, and when she came to herself and found a lovely little boy in her arms burst into tears. She was so sorry that she could not go back and have them all over again under the benign influence of this God-given pain destroyer.

Yet the production of anesthesia for surgical operations we owe to an obscure country doctor in the backwoods of Georgia, Dr. Crawford W. Long. The pains of surgery and maternity annihilated and all things made possible to the surgeon by his ability to do thoroughly and without shock to the patient anything operative which should be found necessary!

CRAWFORD W. LONG.

In the brief time allotted to this address I can not go into all the details of the ether controversy. Dr. Luther H. Grandy, of Atlanta, Ga., in an article published in the *Virginia Medical Monthly* for October, 1893, gives its details. From the papers before him, supported by sworn testimony of those who witnessed the operation, it is clearly proven that Dr. Crawford W. Long removed a tumor from the neck of Mr. James Venable while anesthetized with ether on March 30, 1842. Dr. Long's ledger is produced and from it an extract is taken which shows Mr. Venable's bill for 1842, and reads as follows:

JAMES VENABLE, DR.		
Jan. 28,	Sulphuric ether.. . . .	\$0.25
March 30,	Ether and excising tumor	2.00
May 13,	Sulphuric ether..25
June 6,	Excising tumor.. . . .	2.00

Dr. Long, and later on Dr. J. Marion Sims, published the details of this operation.

On July 3, 1842, Dr. Long amputated the toes of a

negro boy for disease, doing the operation under ether anesthesia.

On Sept. 9, 1843, he extirpated a tumor from the head of Mary Vincent.

On Jan. 8, 1845, he amputated two fingers of a negro boy: two witnesses state that one finger was removed while the negro was anesthetized, and the other one when he was awake, just to show the bystanders that anesthesia was possible.

Dr. W. T. G. Morton, of Boston, gave ether for Dr. J. C. Warren in the Massachusetts General Hospital on Oct. 16, 1846. This was in a public hospital and was heralded over the world by the profession at once, and ether was soon in universal use.

While it is true that the young village doctor of Jefferson, Ga., was the first to use ether for the painless performance of surgical operations, he did not publish the fact until after Morton and Warren had written of their work. Priority of work lies with Crawford W. Long, priority of publication with Morton. Both deserve praise and honor. The timidity and retired, obscure position of the young country doctor prevented him from publishing his discovery to the world, but it was known to his neighbors and friends.

Boston, Mass., has erected a monument to Morton. One stands in Paris commemorating the discovery of the unknown country doctor in the backwoods of Georgia, and the State of Georgia has decided to place his statue in the hall of the immortals at Washington, D. C.

At a later period chloroform supplanted ether in many surgical operations and the profession is largely indebted to Sir James Y. Simpson, of Edinburgh, Scotland for popularizing its use.

Recently there was gathered to his father's house and to "Our Father's house" another man who lived and died in a small town in the mountains of Georgia, and whose name will go sounding down the corridors of time with honor.

ROBERT BATTEY.

Dr. Battey's operation has been merged into Tait's, but he deserves great honor and praise for his bravery in devising an operation for the relief of suffering women. He was as modest as he was gentle and brave, and to know him was to love him for his personality.

The profession was forty years learning the lessons Bernutz and Goupil tried to teach them, and to

LAWSON TAIT.

is due the credit of compelling it to recognize the value of their teachings. They uncovered for us the pathology of certain diseases, and later Neisser and Næggarath taught us their etiology, and as long as time shall last these men will stand out among the Pathfinders of this generation which has furnished so many leaders.

PASTEUR.

Pasteur, by his investigations, ascertained that fermentation was produced by living microorganisms, and that chicken cholera was an infectious disease and could be prevented by vaccinating the flocks with an attenuated virus. He also demonstrated that pebrine, a disease of silk worms, which was destroying the silk industry of France, was microbic and contagious, and hence preventable. He applied the same enthusiasm to his effort to discover the cause of anthrax, as it affected sheep. He found the source of

the disease, cultivated the germs, attenuated them, and by using the weakened germs and their ptomaines protected the flocks of France from destruction. Following up his idea for vaccination for infectious diseases, he has saved many lives from that frightful malady, hydrophobia; and the artisans in the profession have but followed Pasteur's lead in all the work which has led up to the antitoxins of diphtheria, pneumonia and other contagious diseases.

LISTER.

Resting back on Pasteur's work on the cause of fermentation lies the source of the inspiration which filled the soul of Joseph Lister of Edinburgh, and lead him to the experiment which culminated in the triumphs of modern antiseptic and aseptic surgery.

We call the details of modern surgical work Listerism, and correctly we do it, for Sir Joseph was the Pathfinder who led the way, when all the world was buried in the darkness of ignorance. The fact that we may to-day invade, with impunity, any organ of the human body; that thousands of lives are annually saved, that suffering has been lessened, is all due to the labors of these two men; first Pasteur, then Sir Joseph Lister. When the profession fairly learned that suppuration was not "laudable," that surgical inflammation was preventible, and that it was produced by microorganisms, then the pathway was opened for the hunt for the causes of those diseases which were not surgical. And one by one they have yielded up their secrets to the keen eye of the microscopist, aided by Koch and his method of staining tissues to be examined. Robert Koch became a Pathfinder, and when in 1882, he announced that he had discovered the cause of tuberculosis, the world fairly went wild. Since then, what mighty strides have been made in uncovering the sources of many of the scourges which afflict mankind! Consumption, typhoid fever, diphtheria, yellow fever, cholera, leprosy, the infectious diseases, puerperal fever, tetanus, all inflammatory diseases, *et id genus omne*! Malaria has recently yielded its hematizoon to the labors of Laveran, and we predict that the infecting microbe of each of the contagious diseases will be isolated before many years, and all this work, and all the lives saved by modern aseptic and antiseptic surgery, have been made possible by the enthusiasm of Pasteur, the loving, devoted Frenchman, and of Sir Joseph Lister, the laborious Scotchman.

MC DOWELL.

In the early part of this century, there lived in the backwoods of Kentucky, an obscure practitioner who was as brave as Julius Caesar; a man who had "courage of his convictions," who dared to lead where, for long years no man was brave enough to follow. And from the pioneer work of that country doctor in the little Kentucky village, has grown up a host of ovariologists; wherever the operation of ovariectomy is performed and a woman's life saved, there is erected a monument to the name and memory of Ephraim McDowell, the Pathfinder in the field of abdominal surgery. All honor to the obscure, brave and undaunted country doctor in the wilds of Kentucky! And yet, while living, he was abused and maligned as a murderer. When dead, the whole world of medicine and surgery honor his memory.

SENN.

Less than fifty years ago, there was born in a canton in Switzerland a little boy; his parents brought

him to this country, and he grew up to robust manhood in the west; secured a good English education, struggled hard with poverty to secure his medical degree; obtained it with honor, and became an interne in the Cook County Hospital of Chicago, Illinois. A few years ago he took up the suggestion Sims made in 1878, and on dogs demonstrated that abdominal section, ligature of bleeding vessels and suture of wounded viscera, was not only feasible, but entirely practicable. After a great deal of painstaking work and careful experimentation he laid before the professional world the result of his work.

To-day the labors of Nicholas Senn are bearing fruit the world over, and while it is possible that in certain cases the Murphy button may supplant the decalcified bone plates in the intestinal surgery of the future, yet for all time, Nicholas Senn has written his name on the surgical history of the world. And whenever in the future, human life is placed in jeopardy, by wounds of internal organs, whether on the battle field or in the street brawl, and is saved by either of these or any other device, that life will be a monument, first to Sims for suggesting it, and next to Senn for showing the world how to do it.

The warm hearted friend, the enthusiastic, laborious physician, the brilliant operator and orator, the generous donator to the profession of the largest private medical library in the world, Nicholas Senn, will go down to posterity as the Pathfinder in intestinal surgery.

HAIG.

And we venture to place another man in this category of Pathfinders. When the profession realizes that all the cases of migraine or sick headache, diabetes, many of chronic Bright's disease, the cases of so-called idiopathic epilepsy, Raynaud's disease, the cases of so-called neurasthenia and hysteria, all cases of mental depression and consequent suicide, many of the forms of neuritis and the neuralgias and many of the skin diseases, as well as all forms of rheumatism and gout, are but expressions of that dreadful poison which each of us make every day and hour, viz., uric acid; I say, when we realize that all this mass of suffering, probably more than from all other causes put together, is produced by poison of endogenous manufacture, we will have cause to be thankful that personal suffering, with frequent attacks of sick headache, drove Alexander Haig, of London, to investigate uric acid and its protean manifestations.

Future generations will be freed from much suffering by following in the pathway Haig has cut out for us in the dark field of preventable human suffering.

SIMS.

In a little village in South Carolina, in 1836, a young man hung out his shingle for the purpose of practicing medicine. In a month or two the leading man of the village called on him and said: "Marion, have you had a case yet?" being answered in the negative, he was told to go up to the man's house, that the baby was ill. The young doctor went and found a very sick child. He thought the child had cholera infantum; told the family to send to his office in one hour and he would have the medicine ready. To his office he went, and got down from his bookshelf "Eberle on Children," the text-book of that day, and began to read up on cholera infantum. As the time drew near for Jennie to come for the medicine he was no more enlightened than when he began to read. One pecu-

hilarity of Eberle's book was, that there was a prescription on nearly every page. Well, in the young man's bewilderment he did not know what better he could do than to fill the first prescription, and he did it. In after years I heard him tell about it, and he remarked that "he turned a page on that baby every day, and filled the next prescription." When he got along toward the end of his prescriptions, the baby was ready to be transplanted as a rosebud to paradise, but the doctor did not know it. He had never seen death. He had heard the best of lectures, but had never seen sickness; there was no clinical teaching of medicine then. He paid a final visit to the child, and while sitting beside it and watching the little sufferer, suddenly it stopped breathing. Immediately the doctor picked the baby up, lowered its head, and lifting its legs in the air shook it, thinking the child had fainted and that he would thus get some blood into its brain and revive it. The old woman, who had come in to see the child and incidentally to size up the young doctor, placed her hand on his shoulder and said, "Doctor, you need not shake that baby; it is dead!"

It was a pitiful sight to see the young village doctor who had never seen sickness and death, called to prescribe for a sick child; pitiful to see him go to his books and after an hour's reading, fill the first prescription; pitiful to see this doctor "turn a page on that baby every day;" sadder to see him stand by the child's dying couch and utterly fail to realize that the icy fingers of the grim monster were laying their relentless grasp on its heart strings; and sadder still, as the fleeting breath suddenly ceases, to see him raise it up, lower its head and shake it, in a vain endeavor to shake the blood into its lifeless brain; and pitiful to hear the old woman, who had no faith in young doctors, say, "Doctor, you need not shake that baby; it is dead." What more pitiful sight than this? He who goes forth to save life, utterly unacquainted with death!

See this village doctor again. An accident to a woman suddenly reveals to his brain the way to successfully relieve suffering motherhood of a fearful disease, vesico-vaginal fistula, which had, from all time, been incurable, and which renders its victim a hopeless recluse, forever shut out from society. See him again, when he essays to practice those steps which a revelation from heaven has told him is the way to relief, fail utterly to accomplish a cure; again he tries and again he fails! But he believes first in himself, and knows he is right and must succeed. Again and again failure follows fast on failure. He had gathered together from among his acquaintances six women afflicted with this trouble. He supported them entirely at his own expense. He inspired these women with the belief that he could cure them. At first his professional friends assisted him in his operations; but at last they gave it up, and making assistants of his patients, he continued to operate on them; and for four years he kept at it, knowing he must succeed when he had eliminated all his errors. At last about the end of the fourth year, and on one of the women, the thirteenth operation success crowned his efforts. With success came failure of health.

See him again, broken down in health, go to New York to recover it and to tell the story of his successful work in the relief of the surgical diseases of women. See him thus broken in health, and after showing the profession in New York how to do this work, rejected by this profession and the very men to whom he had

loaned his instruments. See him struggling with poverty and distress, the spirit all taken out of him as he feels in his heart that "Man's inhumanity to man makes countless thousands mourn." Alone, without money and without friends, in that great city! Not only without friends in the profession, where his warm heart expected them, but facing their opposition and finding it everywhere, he turned! He says his condition drove him as near crazy as it was possible for him to be and not lose his mind entirely.

See this enthusiastic, warm-hearted man, broken in health, in spirits and in purse; persecuted by the leaders of the profession he went to teach, and God knows they needed it! See him with his wife and children in distress, and his good wife cutting up her new dresses to make her children look respectable at school! But while in the depth of despair he found a friend at last. It is said, you know, that the darkest hour is just before dawn. And whom do you suppose that friend was? Henri L. Stewart, a newspaper reporter! Through him he reached the medical profession who were not connected with medical colleges, as well as those who were, and then the noble women of New York; and his great enterprise was founded. "The stone which the builders rejected, the same has become the head of the corner."

Struggling, in want, rejected by the profession of New York, and absolutely given no opportunity to show that he could cure a hitherto incurable disease! See him in Europe, with all the leading surgeons sitting at his feet, like Saul of Tarsus at the feet of Gamaliel! Invited to operate in the hospitals, congratulated by them on his success, given private cases on which to operate, his name spreading over the whole of the old World! Verily, a prophet is not without honor save in his own country. And while in the midst of these triumphs, on October 18, 1861, he writes his brave, devoted wife that he would not say *that day* was the happiest of all the days of his life, but that it was the proudest save three others. The first of those three other days was the one on which she gave him a rose bud through the garden fence (which rose bud he kept to his dying day); the second when she gave him her hand in marriage; and the third, the first anniversary of the founding of the Woman's Hospital of the State of New York.

From utter failure with the sick child of the village tailor, he became the successful and beloved physician for the crowned heads of Europe, who were glad to decorate him with medals. It is said of him, that there was no capital in the old world in which he could not have all the patients he could attend to in twenty-four hours after his arrival. And to-day, thousands of loving mothers owe their relief from suffering and restoration to the companionship of their kind, to J. Marion Sims!

While the little village of Lancaster, South Carolina, claims him, and Montgomery, Alabama, gave him to the world, yet, he belongs to humanity, and for all future time, the name of Sims is immortalized. Not only will suffering and injured motherhood for all time owe him a debt of gratitude, but until Sims in 1878, advocated before the British Medical Association, that all persons wounded in the abdomen should have their wounded viscera sewed up, and the bleeding vessels ligated, surgeons dared not invade the peritoneal cavity in this class of injuries.

This beautiful city has honored herself by erecting in her borders a well equipped school of medicine

named in his honor. The first hospital ever erected in the world for the treatment of diseases of women, was done by the energy and labors of this man, and stands to-night in the city of New York commemorating his life and work; and that city has also erected a monument in bronze to his memory. It was my privilege to know him personally, and a nobler, gentler, lovelier, braver man never lived than J. Marion Sims, the village doctor, the physician for the crowned heads of Europe, the reliever of woman's suffering! All hail to his God-like character and beloved memory! Here was a Pathfinder whose life and labors you may be proud to emulate, and I commend him to you as an example in every and any walk in life. Through darkest Africa and Asia, over the entire continent of America, and from the frozen steppes of Russia to the sunny, vine-clad hills of Italy, all future generations of women will owe him a debt of gratitude.

Having thus briefly referred to some of the leading men of this country, I beg permission, gentlemen of the graduated class, to conclude my remarks by the briefest allusion to the prospects which are before us. The Science and the Art of Medicine are not yet complete; there are many arduous labors to be performed; there are many brilliant triumphs yet to be achieved, and I doubt not the several members of this youthful, yet brilliant company, will be found in the front rank of that grand army who are to-day laboring to advance the bounds of our theory and to multiply and perfect the resources of our practice.

To the cultivation of true science, to the alleviation of human suffering, to the divine business of going about doing good, and to the leaving of our beloved profession something richer and better than we found, it is the goal toward which we should set our steadfast feet. The accomplishment of these high aims implies on our part, a lifetime of laborious days, and nights devoid of ease, of unwearied patience, of constant mental and physical exertion, of utter self-abnegation. The way is rugged, but the reward is sublime!

ORIGINAL ARTICLES.

TREATMENT OF FIBROIDS OF THE UTERUS.

SURGICAL ENVIRONMENTS. OPERATING ROOM. STERILIZING INSTRUMENTS. LIGATURES AND HANDS. PATIENTS. PREPARATORY AND AFTER TREATMENT. DRAINAGE.

BY FRANKLIN H. MARTIN, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; SURGEON TO WOMAN'S HOSPITAL.

The environments of a patient who is about to submit to a surgical operation for a fibroid of the uterus must be made surgically clean. These environments include operating room, bed, sterilizers, instruments, ligatures and operators' and assistants' hands and clothing.

OPERATING ROOM.

In a private house a room should be selected which has direct light through one or two large windows: a room which can be stripped of furniture, hangings and carpets. It should be convenient to the bedroom of the patient, or better the bed can be placed in the room in readiness for use when the operation is finished—the operating room constituting the bedroom. The woodwork of this room should be thoroughly

scrubbed with soap and water, and the walls and ceiling carefully wiped free of dust. The room should be thoroughly aired by opening the windows and a reliable means of heating should be at hand in order to render it dry and to keep it at a temperature of 80 degrees F. when required. The table, which is selected for the operating table, and the stands for instruments and dressings, together with all receptacles or slop tubs and basins should be carefully scrubbed and then conscientiously wiped with a 1:500 solution of chlorid of mercury. All tin, iron or porcelain basins should be boiled for one-half hour in a wash boiler or other large boiler, as a means of sterilization.

The bed, if possible, should consist of a hair mattress which has recently been purified by steam. In a hospital a large steam sterilizer should be provided where hair mattresses can be sterilized frequently. The bed should be completed with dry sterilized sheets, blankets and pillow slips. If there is no sterilizer at hand the bedding can be sterilized by boiling in water one-half hour, and drying in a pure room, and ironing with a hot iron by an intelligent attendant or nurse. Gowns, towels and aprons should be sterilized in the same manner as the bedding, provided there is no regular steam sterilizer at hand.

In an institution the operating room should have floor and walls of such material that they can be thoroughly washed with antiseptic solutions and provided with a central drain which will allow the cleaning of the walls and floors with water direct from a hydrant through a hose. The drain should be reliably trapped, or better, drain directly in to the external air. For convenience, a perfectly fitted operating room should have several anterooms, including a preparatory room where the solutions are prepared, the water sterilized, and where the heating apparatus for the sterilizers and the sterilizers themselves are located. This room should have washable walls. There should also be one or more anesthetizing rooms, and finally there should be convenient dressing and wash rooms for the surgeon and his assistants. The private operating room which I use at the Woman's Hospital is shown in Fig. 1. It has direct side light and a large skylight. Its walls and floors are of marble. It is lighted at night entirely by incandescent electric lights, gas being impracticable where an anesthetic is necessary; these lights are in abundance, so that an operation can be performed equally well at night or day. The preparatory room is adjacent. This is shown in Fig. 2. It is entirely in marble. The battery of Boeckmann's sterilizers is shown in the foreground. In the farther end are two large tanks in which the water is sterilized for the operation, one being filled with cold sterilized water and the other with hot water. They are connected with the operating room by large faucets which pass through the wall. Directly off from this room is an anesthetizing room, and adjacent to this are two dressing rooms with washing utensils. In the operating room is a spectators' rail which separates the operator, assistants, nurses and all operating paraphernalia from those who may be invited to witness operations.

Sterilizers.—In a private house, in emergency cases, an ordinary copper or tin wash boiler may take the place of the most elaborate sterilizer. The gowns, towels, gauze operating sheets and all large articles used externally can be thoroughly sterilized by boiling for thirty minutes. For sterilizing instruments, silkworm gut, silk and other smaller articles a smaller

kitchen article such as a sauce pan, or porcelain-lined flat pan, may be utilized as a sterilizer.

In large institutions large steam sterilizers are employed. I have used the Arnold sterilizer for dressings and instruments and other small articles until quite recently, since which time I have adopted for my hospital work the Boeckmann steam sterilizer (Fig. 3). These sterilizers are simple in construction, durable, inexpensive, efficient for all work, even the sterilization of catgut, and they possess the advantage of sterilizing with steam, while at the same time when the process is finished the articles are left perfectly dry.

At the Woman's Hospital several of these sterilizers are employed and everything that is liable to be required in several operations is sterilized, and the

for the operation in hand, the balance being reserved for future cases. Tubes of silk and silkworm gut may be prepared in considerable numbers and sterilized by steam with an efficient cotton filter and afterward carried to operations anywhere. On opening, the cotton stopper is first burned down low with the tube, then removed and the skein of material carefully lifted out with sterilized forceps and placed in sterilized water when it is ready for use.

Catgut is the form of absorbable ligature which I employ for buried sutures. I have it sterilized in the Boeckmann sterilizer with dry heat at a temperature of 284 degrees F. for a period of three hours. Previous to sterilization the catgut, cut in suitable lengths, is wrapped in oiled paper, one thread in each paper and the paper enclosed in small hermetically sealed

FIGURE 1.

unopened sterilizers are placed in the operating room for future use. Surgeon's and nurses' gowns, towels, gauze, silk and silkworm gut in cotton-stoppered test tubes are removed as they are required at the time of the operation, while a separate hot water sterilizer (Fig. 4), is employed immediately before the operation for sterilizing the instruments.

Ligatures. I employ braided silk, silkworm gut and catgut for sutures and ligatures. Silk and silkworm gut I sterilize by boiling, or by steam in the Boeckmann sterilizer. They are placed in small skeins in large test tubes loosely stoppered with cotton and subjected to a temperature of boiling water for twenty minutes on two successive days when I have no sterilizer at hand, and to the temperature of the superheated steam for a like length of time in my hospital work. I only open at the operation a sufficient number of tubes

envelopes. While this accomplishes perfect sterilization, as can be demonstrated by bacteriologic tests it has been argued that sterilized catgut may act as a very favorable nidus for the growth of pathogenic germs in tissues in which it is buried, tissues which without the presence of this perfect sterilized culture medium would be competent to resist the few germs left in a wound, after ordinary surgical precautions had been exerted. For this reason I not only render my catgut aseptic with heat but I supplement that process by saturating it with non-poisonous antiseptics. According to Arthur Woodward Booth's admirable article in the *Therapeutic Gazette*, December, 1894, he found that pyoktanin blue in a 1 to 1000 alcoholic solution will render catgut thoroughly antiseptic and at the same time impart to it a longer life. Pyoktanin is a much more powerful antiseptic than

chromic acid and therefore may be employed in more diluted form. Compared with bichlorid of mercury it is a more perfect germicide, non-poisonous, and it imparts a longer life to the gut. Catgut saturated with pyoktatin becomes an antiseptic suture, the antiseptic of which can in no way prove a source of danger.

THE WRITER'S METHOD OF CATGUT PREPARATIONS.

A skein of new catgut is cut into about four lengths. This makes the threads of about forty inches each. Each section of the skein is twisted into a loose knot and they are soaked in ether for twenty-four hours in order to remove the fat. It is then boiled in alcohol, in a closed jar, for one hour in the steam sterilizer,

when the catgut is threaded directly from the bottle. The bottle, or several bottles, with their rubber stoppers may be immersed in a 1 to 1000 bichlorid solution on the instrument table ready to be opened by the surgical nurse in the course of the operation. After it has once been opened I discard any small amount of catgut which may remain after the operation, preferring to use always from a fresh supply.

Instead of boiling the catgut in alcohol it may be sterilized in closed envelopes in the Boeckmann sterilizer as before described, at a temperature of 284 degrees F., and then treated from that point in the same way as that sterilized by boiling in alcohol.

It seems to me that this is an ideal and simple method of catgut preparation. There can be no doubt

FIGURE 2.

Before boiling in alcohol the bunches are divided into their separate threads and each thread twisted into a little coil. After the sterilization by alcohol it is carefully removed from the jar by an intelligent conscientious nurse, with sterilized forceps in sterilized hands, to a jar containing a solution of pyoktatin 1 to 1000 in absolute alcohol. Here it is allowed to remain for twenty-four hours in order to become thoroughly saturated with that powerful antiseptic. I then have it distributed into small wide-mouthed one-half ounce bottles, containing oil of juniper. Into each of these bottles about four of the forty-inch strands are placed. The bottle is then corked with a rubber stopper and is not opened until it is to be used at an operation,

of its absolute sterilization after it has been boiled in alcohol for two hours, or after it has been submitted for three hours to a temperature of 284 degrees F. in the sealed envelopes in the Boeckmann sterilizer.

Dr. Booth found that pyoktatin permeated every fiber of catgut when it had lain in a 1 to 1000 alcoholic solution of the drug for twenty-four hours.

Dr. Booth quotes Sternberg as quoting Jaenicke on the antiseptic properties of pyoktatin as follows:

Staphylococcus pyogenes aureus restrained by solution of 1 to 2,000,000; bacillus anthrax aureus restrained by solution of 1 to 1,000,000; streptococcus pyogenes aureus restrained by solution of 1 to 333,000. In blood serum stronger solutions are required.

Thus we have not only a sterile catgut, but we have that sterile catgut thoroughly saturated with an efficient and non-poisonous antiseptic. The juniper oil preserves the catgut indefinitely, it fixes the methyl blue so that it will not stain the hands, and it keeps the catgut soft and pliable.

The life of the catgut in the tissues prepared by this method is a little less than that prepared by chromic acid, but considerably longer than that prepared by bichlorid of mercury. By placing it in small bottles it can be handled economically without the necessity of ever being obliged to open twice the same supply.

Sponges.—Sea sponges are not safe when prepared under the most careful supervision, whereas gauze sponges may be perfectly reliable whenever there is the simplest device at hand in which they may be boiled.

The best gauze sponges are made from loose-mesh gauze folded into three or four thicknesses, with the edges fastened with a running stitch of cotton thread. They may be made of any size. These sponges are sterilized in a steam sterilizer, or in emergency cases they may be sterilized by boiling with the instruments.

FIGURE 3.

In laparotomy cases I prefer these sterilized by the dry method. They are then used but once and are discarded. This is not economical because of the large number of sponges frequently required, nor is it necessary. The advantage possessed by the dry sponge is in the increased absorptive power of the gauze.

Gauze. The writer has devised an apparatus in which to sterilize gauze for operations, either for hospital operations or operations away from home. Chas. Truax, Greene & Co. kindly constructed this apparatus for me, as well as the furniture shown in the operating room in Fig. 1. It consists of a little stand which fits into the catgut sterilizer of the Boeckmann apparatus, or which can be set into any steam sterilizer (Fig. 5). The stand contains seven large test tubes, two inches in diameter, and about eight inches in length. In each of these tubes can be placed all the gauze of any one kind that will be required at any ordinary operation, which is about two yards of sheet iodoform gauze. Ordinarily I have two tubes filled with iodoform sheet gauze, one with plain sterilized gauze, one with one-inch strip iodoform gauze cut the strong way of the

cloth, one with two-inch strip iodoform gauze cut in the same way, and one with a skein of silkworm gut and a skein of braided silk. These tubes are loosely filled and their mouths closed with cotton. They are then subjected to steam sterilization in the Boeckmann or other steam sterilizer at maximum heat for one hour. They are then set aside and the following day they are again subjected to the superheated steam for one hour, and then dried by removing the cork in the top of the Boeckmann sterilizer so as to get the action of the dry heat. The contents of the tube are now thoroughly and permanently sterilized, and will remain so for weeks if the cotton stoppers in the mouth of the tubes are not removed.

When I wish to preserve these tubes for indefinite use I have the nurse slip a sterilized rubber cap over the cotton and the end of the tube before removing them from the sterilizer. They may then be set aside for an indefinite time.

When I wish to operate away from the hospital, I place the rack containing the tubes required into a metal box (Fig. 6), and that in turn is stored away in my instrument bag.

Preparation of Operator and Assistants.—It should not only be taken for granted but should be insisted on, that any and all persons participating in the high calling of surgery should take a general bath, including the hair, every day.

Dress.—For important operating, such as we have to deal with, special dress for the operator and assistants is indispensable. Suits of white ducking or linen should displace the street apparel. Over this sterilized gowns should be worn. In this dress the operator can be comfortable and do hard work in a temperature of 80 degrees F. When he is through operating all wet clothing, made so by perspiration and the fluids of the operating room, can be replaced by his ordinary dry out-door dress and the reminders of the operating room are left behind.

Preparation of Hands.—After the nails are filed short and smooth the hands and forearms should be thoroughly scrubbed for fifteen minutes in hot water with a stiff nail brush and plenty of pure soap. The water should be changed at least five times. The time should be estimated by an actual time piece and not by guess work. A nurse should supervise this part of the work in important operations, and report to the responsible chief any laxity on the part of any participant. The spaces beneath the nails should be thoroughly brushed and the undersurface of the nail scraped with a steel nail cleaner. After the soap and water scrubbing, the hands should be washed in alcohol and then immersed in 1:1000 bichlorid of mercury solution, and this solution brought into contact with all irregularities by means of the hand brush. The hands should, finally, be rinsed in warm sterilized water. Before beginning the operation the hands should be rinsed in hot water which is placed in a basin close to the operator, so that it may be used from time to time during the operation. After the hands are once washed they should not be allowed to come in contact with anything before or during the operation which is not surgically sterile.

Arrangement of Operating Room.—The steam or dry heat sterilizers containing dressings should be convenient to the nurse. Reservoirs of sterilized water, hot and cold, should be placed near the sponge table. Two large glass irrigators should be at hand. The table with which the Trendelenburg position may

be obtained is necessary, and should be placed in an advantageous position for light and assistants. For a laparotomy, the arrangement of the furniture and participants of the operating room should be approximately as follows: The table near the center of the room with the head of the patient near the chief window. Anesthetizer at head of patient. Operator on right of table (from head). Chief assistant and assistants opposite the operator with the chief nearer the head of the table. The surgical nurse in charge of instruments at stand to right of operator. Nurse in charge at foot of table with sponge dish on small stand in reach of second assistant. Assistant nurse to her right, the latter to work sponges, and to attend to irrigators, sterilized water, etc. Superintending nurse without regular assignment, ready for emergency. To left of operator, small table with sterilized solution for hands. Back of the assistants a similar table. Visiting physicians, admitted after everything is ready for the operation to begin, are arranged around the room out of reach of the operating corps, or any concerned in the operation.

If the case is one where a vaginal operation is required, the head of the patient is directed away from the window, and the patient in the exaggerated lithotomy position is placed with the buttocks directed toward the light. The limbs are supported on either side by two assistants. The operator sits at the foot

primary details. The following summarizes the signs of chronic interstitial nephritis: Lowered specific gravity of urine: patient arising at night to void urine (when there is no bladder or urethral disease to give rise to such a procedure); an enlarged heart with accentuated second sound; a tense pulse and diminished urea. Albumin is frequently absent. The diagnosis is doubly sure when hyaline casts are found.

Every patient should be scrutinized in all these points. If the foregoing state of affairs exist to a marked degree I refuse to operate. If, however, with the above symptoms I find a normal quantity of urine, which does not show a reduced specific gravity under 1010 to 1014 and the amount of urea does not sink lower than six or seven grains to the ounce, if the patient is well preserved generally without advanced heart disease, I am confident that I can operate with safety, if I can secure proper preparation.

I prepare these patients, first by placing them on an exclusive farinaceous diet with milk and fruit for an indefinite number of days before the operation. A week or ten days before the operation a diuretic is added with instructions to drink large quantities of water, the object being to increase the daily quantity of urine from 60 to 100 ounces, in order to thoroughly flush the kidneys and rid the patient of dangerous accumulations. With 60 to 100 ounces of urine flowing for several days, with the patient living

FIGURE 4.—Boeckmann's Instrument Sterilizer.

of the table with the instruments at his right hand. To the left is the nurse with sponges and the irrigator.

PREPARATORY TREATMENT OF PATIENT FOR LAPAROTOMY OR VAGINAL OPERATIONS.

Kidneys.—The failure to recognize obscure kidney disease in patients before submitting them to a severe operation has been the cause of many avoidable deaths. We should not only recognize kidney difficulties in every case but we should also know when a case is laboring under some form of kidney trouble, whether that stage has been reached beyond which it is safe to proceed. It is not enough that the urine in any given case is approximately of normal quantity, of approximately normal specific gravity, and that it gives negative results in tests for albumin and sugar. It is necessary to learn the history of the case, to estimate the specific gravity in a twenty-four hour specimen, to ascertain the amount of urea for twenty-four hours, and supplement this with a thorough and complete microscopic examination.

In diabetes we should not operate. In interstitial nephritis when the disease is not far advanced an operation may be risked with proper preparatory treatment. These latter cases are the very ones which from their great difficulty of diagnosis are often neglected, and consequently disaster results. The importance of the subject must be my excuse for entering into

on a non-nitrogenous diet, with the urea in improved proportion considering the diet, I feel safe in risking an operation.

Dr. Charles W. Purdy, who has had an enormous experience in watching the behavior of kidney diseases under operations, says in reference to *chronic parenchymatous* nephritis: "I see no reason why these cases, if unaccompanied with dropsy may not be operated upon if carefully selected."

Bowels.—In preparing patients for an ordinary laparotomy I begin preparations of the bowels two nights before the morning of the operation. The first point is to seek thorough emptying of the bowels throughout their entire length. The second point should be to render their contents thoroughly aseptic and the third should be to impart to them a maximum tonic.

The bowels are emptied by means of mercurials and salines. The first night of preparation, six grains of blue mass are given. The next morning at 6 A.M., one drachm doses of citrate of magnesia are given every hour until the bowels move, or feel as though they would move with the aid of a small enema. This ought to insure a thorough movement of the entire length of the intestinal canal. If the movements are such, with the above treatment, to insure a thorough evacuation, and to start a free flow of bile, as indicated by the yellow glistening appearance of the stool,

no further catharsis is necessary. The lower bowel should be thoroughly evacuated, however, by the employment of large enemas of soap and water, repeated four or five times during this second day of preparation. The last enema should be given late in the afternoon of this second day of preparation, if the operation is to be done the following morning, and the next morning if the operation is to be performed in the afternoon. The bowels are rendered aseptic by large doses of bismuth and salol. During the first and second days of preparation, gr. x of salol and gr. xx of subnitrate of bismuth should be given every six hours.

The bowels are stimulated by means of carminatives, alcoholic stimulants and strychnin. The second day of preparation 1 drachm doses of tr. of cardomon in one ounce of brandy are given every six hours. Strychnin is commenced three days before the operation in 1-40 gr. doses every eight hours, and gradually increased in quantity until 1-20 gr. doses are given. The bowels should be kept in a thoroughly aseptic condition by feeding the patient a milk diet for two days before the operation.

External Preparations of the Patient.—The first day of the preparation the patient should receive a thorough general bath and then be placed in clean clothing and a clean bed. The abdomen should then be rubbed with a saturated solution of permanganate

FIGURE 5.

FIGURE 6.

of potassium until it is of a uniform mahogany color. This should be scrubbed off by means of a sponge or brush and the application of a saturated solution of oxalic acid. A green soap compress should be bound on the abdomen, this latter to remain all night. Vaginal douches of, first, soap and water; second, 1:5000 bichlorid solution, and third, plain sterilized water should be employed this first night. These should be repeated the night before the operation, and a last vaginal douche given immediately before the operation. The second night of preparation should begin with shaving of the abdomen and pubis, and should be followed by applying a bichlorid compress. Immediately before the operation, after this compress is removed, the abdomen should be scrubbed with green soap and hot water, this to be followed with alcohol or ether, and covered with an antiseptic towel until the incision is made.

The bladder should be evacuated by means of a catheter immediately before the operation.

Dress. The patient is to be put in a long, loose, woolen night gown immediately after an operation, and is thoroughly covered, except the abdomen, with flannel blankets during the operation.

Operation. I am suspicious of an operator who operates on time. The best operators are those who operate well in the smallest space of time; this

implies that the best operators are slow operators. An abdominal incision should be a clean, true, unhaggled cut, so that accurate coaptation is possible. Cold sponges should be employed on the external incision in order to contract the capillary vessels and check their bleeding without the necessity of forceps. Forceps should be employed, however, everywhere in abdominal surgery that their use will save blood, because most of our old-fashioned shock was caused by unnecessary loss of blood. Keep the operative field free from oozing points if possible, even at the loss of a little time. The peritoneum is best opened between two catch forceps elevated so as to present a thin fold. After a small opening is made, the finger passed into the cavity should act as a guide upon which to complete the incision. The peritoneal edges should be attached to the integumentary edges by means of catch forceps, to prevent its peeling off from the abdominal walls in the subsequent manipulation. In all pelvic surgery of smaller tumors the pelvis should at this point be elevated by means of the Trendelenburg table; the elevation being sufficient to draw the bowels away from the field of operation, and to elevate the contents of the pelvis. Sterilized silk or catgut should be employed for any pedicle which it is safe to tie and drop. Catgut may be employed to close simple peritoneal rents.

Drainage should be employed in all cases where extensive enucleation has occurred, where there is a slow venous oozing from separated adhesions or where aseptic matter has in any way contaminated the peritoneum. Drainage, in competent hands, never does any harm, therefore, where there is the slightest doubt, it should be employed. It has saved many lives, and made more comfortable those who might not have died without it, but who have been given the advantage of it.

After my operation is finished, the peritoneal cavity is thoroughly dried; then if there has been at the operation a process of enucleation, leaving of necessity slight oozing points, or in cases where ordinary adhesions have been separated, after drying the cavity as far as possible, I place in the cul-de-sac a glass drainage tube and pump out any remaining fluid. I next protect the abdominal contents from the abdominal wound with a large flat sponge, and insert the sutures, after which I again pump the drainage tube. If there is more than a drachm of bloody fluid, I leave the tube in until the sutures are nearly all tied and the sponge removed; then I make a last trial of the tube. If the fluid amounts to one-half drachm or more, and is bloody, I allow the tube to remain; if, on the contrary, the tube is nearly dry, or the contents is simply colored water, the result of flush, if it has been employed, I remove the tube. What has been done influences one in regard to drainage. I almost invariably drain after it has been necessary to flush. I believe the peritoneum is satisfied, to an extent by the flushing, and will consequently neglect, in a degree, to absorb any remaining fluid. Experience seems to sustain that argument. Mikulicz drain is almost indispensable in a limited number of cases. Cavities may be packed with gauze which can not be reached with glass drainage tubes. Hemorrhages in cavities so packed will cease, when a glass drain would not avail. Operations are now possible with the Mikulicz drain which were impossible without it. The question about drainage is not, shall we drain, but how, and how often.

To Prevent Intestinal Obstruction.—In abdominal surgery one is constantly watching the behavior of the intestines. They are our prominent point of attack in our preparatory treatment, they are our greatest source of anxiety during the operation, and upon their management after the operation much watchfulness is imposed. All of this anxiety is caused by our desire (with the exception of care against wounding when operating) to prevent obstruction. It, therefore, is a point in the technique of this work to which discussion may profitably be directed.

The pathology of obstructions is well summed up by a valuable contribution on this subject by Dr. Ashton, of Philadelphia, from which I quote:

"Adhesions between the intestines and raw surfaces: *a*, to an omental stump; *b*, to the edges of the vaginal wound following supra-pubic or vaginal hysterectomy; *c*, to a pedicle; *d*, to raw surfaces on the intestinal wall.

"2. Paralysis of the intestines.

"3. Local spasm of the intestines.

"4. Impacted feces.

"5. Bands of inflammatory lymph.

"6. Adhesions between coils of intestines or between the gut and neighboring parts, due to traumatic inflammation.

"7. Kinking or twisting of the intestines, due to faulty technique.

"8. Including the intestines within the loop of a suture of the abdominal wall, or between the edges of the abdominal incision.

"9. Slipping of a coil of intestines through a slit or an aperture."

Under the first head, "Adhesions between the intestines and raw surfaces," we must seek our remedy during and following the operation. Intestines should be handled and exposed as little as possible in order not to produce hyperemia or denudation of their surfaces. An omental stump of any considerable size should be selveged by inverting its raw edges with a running catgut, or with ligature. When denudations of the pelvic or intestinal peritoneum can not be reinforced by a superabundance in the neighborhood, care should be taken to carefully arrange the intestines in as near the normal position as possible. A pedicle of large size should be covered by securing over its end the peritoneal covering with a running stitch of catgut. Raw surfaces of any considerable size on the intestines should be covered with peritoneum if possible, with the edges well secured. Paralysis of the intestines may be avoided by emptying them thoroughly previous to the operation of all irritating matter (which may ferment and cause distension) by rendering the contents aseptic by means of bismuth and salol, and the employment of full doses of strychnia to act as a muscular tonic. Carminatives, such as wintergreen, cardamon, etc. may also be employed as antiseptics and muscular tonics. During the operation the intestines should not be handled or chilled in order to avoid paralysis. After the operation, nourishment of non-fermentive and easily absorbable nature should be employed. The bowels should be stimulated to early action in order to keep them empty and avoid the beginning of distention, which soon leads to paralysis. An early movement of the bowels, or free passage of flatus, assures a normal disposition of the bowels as regards location. If they adhere after such time, it will be in an advantageous, not cramped position.

A flat sponge beneath the abdominal wound, after carefully spreading down the omentum and before the wound sutures are inserted, will avoid including an intestine within the loop of a suture, or between the edges of the abdominal wound.

When ventral fixation of the uterus is practiced, great care should be exercised in disposing of the intestines in such a manner as to avoid their slipping through the opening left between the uterus and the abdominal wound.

AFTER-TREATMENT.

The immediate after-treatment consists in stimulating the patient out of any tendency to nervous shock which may exist. She should be surrounded in bed with dry heat, and in hospitals placed on a water bed. If there has been any considerable loss of blood, the feet may be elevated in order to restore blood pressure in the brain. In severe cases of shock from loss of blood, it is well to bandage the blood out of the lower extremities by means of elastic bandages. A saline solution under the integument may assist to fill the blood vessels. Oftentimes the difficulty is not lack of fluids so much as lack of tone, which allows a patient to bleed to death, as some one has put it, "into her own dilated capillaries and venules." Here direct arterial stimulants and vaso-constrictor remedies are called for, as well as strong nerve stimulants. In these cases, I immediately order hypodermics of nitroglycerin, strychnin and digitalin. Stimulating enemmas of whisky and warm water may also be given. What is done for shock should be done promptly, as patients who are allowed to go on for a few hours with a sub-normal temperature and high pulse, are with great difficulty restored.

Dressing Glass Drainage Tube.—The glass drainage tube, when it is allowed to remain, should be emptied with a syringe with a long rubber nozzle the first time in one hour. If the fluid is more than a drachm it should be dressed again in an hour, if a drachm or less, the interval between dressings should be increased one hour, and the same rule followed until the fluid is less than a drachm and of a light amber color, and the interval from four to six hours. At this time the tube may be removed. If it is left longer than thirty-six hours, a piece of sterilized gauze should be put in its place for six hours, when the latter is removed and the wound is closed with slight pressure and its closure is obtained by extra pressure of external straps.

Care of Capillary Gauze Drain.—If capillary gauze drain has been employed instead of the glass drainage, the protruding gauze (from vagina or abdominal wound) should be kept abundantly covered with a pad of loose fluffy gauze, and this should be changed as often as it becomes saturated with fluids. If all drainage ceases in twelve to twenty-four hours as indicated by dry dressings, the gauze packing may be removed. However, if drainage is free and patient is normal it may remain forty-eight to sixty-two hours. When it is possible this drainage should have its exit through the vagina. After it has been removed a loose gauze packing should be placed over the wound.

Dressings.—The wound is closed with silkworm gut, including all parts of the wound edges, and dusted with sterilized iodoform, and the dressing is a thick one of iodoform gauze, held in place by adhesive straps tight enough to take the strain off the sutures without puckering the integument. Over

this is placed a good allowance of absorbent cotton, and all retained with a binder. The dressings are not disturbed for four days unless there is pain or temperature. At the end of the fourth day the dressings are carefully removed, and the wound is thoroughly but carefully washed with equal parts of 95 per cent. alcohol and 1:5000 bichlorid solution. Iodoform is again applied and the dressings renewed. The seventh day, before the stitches are removed, I again have the wound washed in the same manner and, after their removal, dressed as before.

In vaginal operations the vaginal wound is dusted with sterilized iodoform and the vagina loosely packed with strip gauze. It is removed in forty-eight hours and after twelve hours vaginal douches of bichlorid of mercury solution followed by plain water are employed once or twice daily.

Bowels.—If flatus has not passed freely, per rectum, in twelve hours by the simple employment of a rectal tube, I employ the "one, one, one" enema, one ounce of sulphate of magnesia, one ounce glycerin and one ounce water. If this does not start the gas in two hours, I order it repeated in double quantity. If this enema is not retained, and flatus has not passed, I order an enema of soap and water one pint, with one-half drachm of turpentine. If they are still obdurate, I begin one-half grain doses of calomel in ten grains of bicarbonate of soda, given every two hours for four doses, or until gas passes, alternated with drachm doses each of gran. citrate magnesia and sulphate magnesia in an ounce of water. Following these remedies in one hour, another "one, one, one" enema is given. It must be an obstinate case indeed that will not yield under the above remedies. If the stomach is irritable and will not tolerate the bicarbonate of soda, the calomel may be given dry on the tongue. Other salines may be substituted for the above if they are objectionable. The bowels should be moved from above on the fifth day with small doses of some effervescent salt, or, if required, a more vigorous laxative.

Diet.—First week, fluids; second week, semi-solids; third week, semi-solid and solid food in small quantities; fourth week, good substantial food, with a few curtailments. As soon as the patient is out of the anesthetic, I begin to give hot water in teaspoonful doses as often as every fifteen minutes. If the stomach tolerates this, the quantity is increased to one-half ounce, and the interval may be increased in length. If the patient is nauseated and the hot water causes vomiting (and it should be hot water), or increases the nausea, it should be withheld. When the patient can take the hot water, and still complains of thirst and begs for cold water the nurse is instructed to let her rinse her mouth with cold water. Ginger ale is a good alternate with water for the first twenty-four hours. After twelve hours, drachm doses of peptonized milk may be sandwiched with the water. If peptonized milk is offensive, plain sterilized milk may be substituted, or sterilized milk and lime water. Milk in some form, I feel to be the most perfect food. It should be increased every hour until $\frac{1}{2}$ ounce doses are given by twenty-four hours, to one ounce by forty-eight hours, and to two ounces by the end of sixty-eight hours. Barley water may be alternated with the milk. Later, the monotony may be relieved with the meat and shell-fish broths, thin gruels, etc. The fourth or fifth day the patient may be allowed to extract the juice of broiled beef by chewing it; the fiber, of

course, should be rejected. Tea may be given the second or third day as a relish. Orange juice, and the juice of other fruits, may be given in small quantities the third or fourth day. Rules can not be laid down in regard to the diet of these patients, general principles only can be hinted at. The patient should be seen each day and her wants studied. If stimulants are required, one of the best is good brandy. Champagne is all right if its sweetness does not make it objectionable. If patients are unable to retain enough by stomach to properly nourish them, enemas of either milk or stimulants should be resorted to.

Getting Up.—Uncomplicated laparotomy cases are gradually bolstered up until they can sit in a bed with a bed rest at about the fifteenth or sixteenth day, sit up in a large chair at the twenty-first day, and leave the hospital from the twenty-eighth to the fortieth day.

SERO-THERAPY IN THE TREATMENT OF TUBERCULOSIS; REPORT OF CASES.

Read before the St. Louis Medical Society, March, 1896.

BY PAUL PAQUIN, M.D.

In January, 1895, I had the honor of submitting to the St. Louis Medical Society, a report of experiments made at the St. Louis City Hospital and at the Poorhouse in the treatment of 22 cases of pulmonary consumption, all of which were in the second and third stages. This report was rather premature. Had it been possible, it would have been delayed much longer in order to establish better the results of the clinical work done. But circumstances, over which I had not sufficient control, made it imperative for me to present the experiments at that early date. I was highly gratified, however, by the encouragement given me by a few of the many excellent men in this Society, and later on by eminent physicians of other societies, where I had the honor to read papers on the same subject. But, as usual, in such instances, by far the largest number of physicians who heard and read the reports were very skeptical, and some of them, without the least investigation, or with cursory examination into the question, passed severe criticisms and even attempted to break the force of clinical argument without justice or logic. To-day, I have the honor to report more than a year's work, covering all the results obtained directly or indirectly, by me by sero-therapy in consumption, in cases treated longer than three months, discharged, abandoned or dead.

To those of my critics who would or could see nothing valuable or scientific in the production of immunized horse blood serum in the treatment of tuberculosis, I beg to refer to the labors of Bernheim in 1890, who attempted the transfusion of goat blood in the treatment of pulmonary tuberculosis; Bertin and Picq, who in the same year tried the same thing in tuberculous rabbits; Coupard and St. Hilaire, who in 1891, injected dog serum in the trachea in pulmonary tuberculosis; Héricourt, who in the same year treated tuberculosis in man with dog blood serum; De Schweinitz on guinea pig immunization in 1894; Babés and many other European scientists who experimented with dog blood serum up to 1895; and, finally Maragliano, who increased the immunized property of the serum of the ass and treated patients successfully, and, announced that he had arrested tuberculosis in rabbits by the use of equine serum immunized, which was done precisely on the lines

followed in the work of your humble servant, began some years back, carried on irregularly afterward under extreme difficulties (with meagre laboratory facilities, precluding proper uninterrupted animal experiment), and practically applied in 1895. In discussing sero-therapy in tuberculosis, I will have occasion to refer to sero-therapy in diphtheria and other diseases.

At the outset, let me say that one must study very thoroughly the true cause of the principles underlying the cure of pulmonary consumption, to reason out the means by which serum or any other treatment may arrest this fatal malady.

One unfortunate result of bacteriology has been the establishment of the almost universal belief that pulmonary consumption is due exclusively to the bacillus of Koch; and that no other cause need exist in the system; that any human being with tubercle-bacilli in the system has for that reason tuberculosis of a serious character, irrespective of physiologic factors indicating and sustaining health and without regard to any pathologic conditions assisting in morbid developments. As a matter of fact, there is probably no human being wholly free from occasional contamination by the tubercle bacilli. Tizzoni has clearly proven by post-mortem examinations of beings killed accidentally, that, a large percentage of the human race who die from other causes have bacillary glands without the development of serious morbid phenomena. The germs of consumption develop and result in serious consequences in the tissues only when the soil is fit for their growth and nature's natural defensive forces are lowered. It is then that the fight for supremacy between the cells of the organism and the parasitic germs invading them, result in victory for the enemy and destruction and death of the body. This should be remembered in therapeutics.

If it has proven anything, sero-therapy has pointed out clearly that it is not as a germ-killer that serum acts in any disease, but as an agent physiologically antagonistic and capable of neutralizing in some other way, the effects of the poisons of the germs on the system. In diphtheria, it is clearly proven, that while serum does arrest the disease at once, germs remain in the throat many weeks afterward. It is evident that the serum in such a malady gives nature simply a chance to defend itself against the germs and their toxic products. So it is with other diseases which are treated with serum. The serum simply neutralizes the effects of the toxins in a preventive manner and thereby gives nature a chance to strengthen its forces and in time destroy the microbes that may invade it. Consequently, it will be obvious to all, that every case of tuberculosis can not yield alike to the serum treatment or any other treatment, and, that we must consider the disease, not only as to the action of the toxins of the bacilli of tuberculosis but also as to the toxins of other germs, and the ravages made in the tissues, such as infiltrations, nodules, softening, cavities and the various other lesions, which interfere more or less with the functions of the nervous system, respiration and circulation, and which once formed, are sufficient to lead to death independently.

THE IMMUNIZATION OF HORSES FOR THE PRODUCTION OF ANTI-TUBERCLE SERUM.

The principles underlying the condition known as immunity are two-fold, viz. those which underlie natural immunity and those which underlie acquired immunity.

Natural immunity may be complete, absolute, or it may be relative. When absolute, it seems to depend more on a certain deficiency in nutritive elements upon which the specific germs must feed and live, than on any other factor. Acquired immunity, which probably is never permanent, seems to depend chiefly, if not wholly, upon special defensive forces created for the occasion by nature in an organism invaded by pathogenous microbes or impregnated with their products. These special forces have been proclaimed as being two or three in number. The first of more doubtful nature to-day than it was some months ago, and not believed in now by most observers, is the product by the cells of the affected organism of an agent with the alleged power to neutralize chemically, the poison generated by the microbes living at the expense of tissue, blood and lymph. If Behring's law was formulated on this hypothesis, as the word antitoxin implies, it is not well founded, although its application is practicable and correct on other more probable grounds of immunity.

The second, and probably the true defensive force, better demonstrated than the former, is the increase in number and perhaps in the quality of the phagocytes, whose chief duty it is to destroy foreign microscopic organisms and their products, and, foreign particles and assist in the repair of organic breaches.

The third, theoretical and vague, is the increase of general vitality of the organism and the assimilating and disassimilating power of the cells of the body, a very important adjunct or assisting force, which in therapeutics as in experiments, should receive grave consideration. Such is the conclusion, I opine, one will usually reach after careful study of the reports of the foremost experimentalists and clinicians of the age, to this date.

The equine species possess a relative immunity to the germs of tuberculosis. While it is occasionally possible to produce experimentally local and rarely, it is said, a more or less extensive general infection in the horse and the ass, some of these animals react quickly to hypodermic injections of the tubercle poison itself, that is to say, the product of or substance forming the structure of the tubercle bacilli. Hence, there exists serious difficulties in the way of experimentally endeavoring to immunize equine blood for therapeutic purposes. Some of these animals are more deficient than others in the nutritive qualities necessary for the proper nourishment of the bacilli, and, consequently react poorly; others react much more to the toxins of the destructive germs; the result is that the so-called antitoxin produced varies according to the susceptibility of the animal treated with the toxins. Here arises one of the serious problems besetting all investigators in their efforts to establish a positive method of estimating the antitoxic, or more properly speaking, the therapeutic value of anti-tubercle serum. A horse failing to react to the toxins or to the desiccated bacilli (tox-albumins and other matters of or in the substance of germ structure) after two or three months of injections, may be considered immunized properly if one does not consider the pre-existing natural immunity of the animal, but its serum may be found comparatively deficient in therapeutic potency, for instance, in the power to increase phagocytosis, for, as stated before, it is the properly acquired immunity (long experience with which will force thorough appreciation) that produces the effect-

ive therapeutic agent. It is the same acquired potency which acts in diphtheria, tetanus, etc.

In the past, I expressed theoretically, the idea that possibly the natural serum of a horse, apparently antagonistic to the bacilli of tuberculosis, contained a natural antitoxin which was merely increased by immunizing injections, but I have almost arrived at an opposite conclusion on this point. The light shed more and more glaringly every day by the study and application of the Behring law and the studies of other biologic questions, in experiments and clinical tests, point strongly to the theory that therapeutic serum, whatever its chemistry or biology, is a physiologic element manufactured purposely by nature, if I may so speak, as a defensive power as above mentioned. This explains, in part at least, the rapid success clinically, without immediate bactericidal effects of the serum in diphtheria, particularly in the earliest part of the disease, and also of the comparatively quick success of the tubercle antitoxin in acute cases of pure tuberculosis, or tuberculous pneumonia, before extensive transformation or destruction of tissue, as will be seen further.

The immunized serum of the horse in tuberculosis is essentially due to the careful, continuous process of saturation of the system with tubercle toxins (and even the germs sometimes) without allowing the advent of any lesion or any serious constitutional disturbance or disease, and with the production of the least amount of poisonous waste matter in the blood. Other therapeutic serums are or should be produced on the same grounds.

Herein arises a very important question in the production of all kinds of serums which even advanced experimentalists would do very well to study more closely, and which those ignorant of the nature, physiology and pathology of the lower animals, meagerly equipped or wholly untrained for laboratory investigation, and who assume to try the production of antitoxin for use in the human system, must always find a dangerous stumbling block. It is a question, indeed, which forces on the mind of the profession the great risk that its members run of causing poisoning or of using ineffective, useless serums, and thus fail to save life when they depend on inexperienced sources for such products, for therapeutic purposes. There exists, as will be seen, really grave dangers in serum from incompetent producers. The health of the animal to be immunized must be positively ascertained, not only with reference to such fatal maladies as glanders, which only experts can safely diagnose in the early stages, but with reference to any indisposition or morbid conditions often very difficult to recognize, during which the economy will produce in the blood agents more or less deleterious, and which may perhaps be fatally poisonous when introduced into man's circulation. In my experience, the serum of an animal which has not even been touched except to make the diagnosis of his condition, sometimes produce in man fever, local erythema, urticaria, cellulitis and other untoward symptoms of a more grave character. These symptoms in the beginning of my clinical tests and last summer were more common because of our ignorance then on many problems bearing on the nature of serum, most of which are clearing up before persistent inquiry, instituted more scrupulously in the last few months. It must be that the blood of animals, whether immunized or not, sometimes contains sub-

stances of an irritant, poisonous character, possibly of the order of leucotoxins or some special cellular toxic products, which are not rejected with sufficient rapidity, perhaps, by the usual channels of excretion. Hence the necessity of watching and applying proper hygienic measures and sometimes special therapy to animals under process of immunization, in which analytical and physical indications point to improper disassimilation. Naturally, one must have and should apply a good knowledge of the physiology and pathology of lower animals, to be able to judge of these conditions. But unfortunately, for the public and and for the profession, ignorance of veterinary science does not seem to deter those who are bent on revenue only, from the attempted production of organic, therapeutic agents, requiring for their preparation special training or fitness which they do not possess.

Realizing this important question in full force, we are doing more scrupulous work than ever in this line. In fact, we did not deem it so important in the beginning of our clinical trials because we relied too much on foreign experimentalists in sero-therapy, who proclaimed the *innocuousness* of serum; relied, too, on our first results which were so remarkably free from accidents as to have been misleading. We are now, I believe, deciphering some of the causes of certain objectionable symptoms that sometimes follow sero-therapy in *any* disease. The fact that more than fifty thousand injections of the serum I produce for the treatment of tuberculosis have been made in human beings with not a serious accident and far less a fatal result, which can not be said of *all antitoxins*, shows that it is not likely to do much harm, and the reports in given cases show its value in certain conditions. We will always find in sero-therapy, as in all other forms of therapy, susceptible organisms and idiosyncrasies which militate against the use of serum hypodermically, but they are not very common—there remains for these, rectal injections, the value of which I am not yet, however, ready to assure.

To recapitulate briefly then, the horse or other animal to be immunized should be healthy to begin with and watched daily and treated properly. The accomplishment of this is a matter depending on proper equipment and qualifications enabling the proper study and analysis and care of the animals to a degree of safety for the profession and the patients.

The health determined, the degree of natural immunity should be established. The natural toxic powers of the blood should be determined and the daily or less frequent immunizing toxin dose should be regulated, the quantity varying usually between 1 c.c. and 10 c.c. followed or not by bacillar tox-albumins, according to the indications, bearing in mind the reaction produced and the general effects on the economy, as evinced by thermal readings, the physical and chemie nature of the urinary secretion (when analysis is indicated), and by various symptoms which experience will reveal to the trained observer and experimentalist, all of which scrutiny we apply with strict diligence in our work.

We have purposely used, in the past, all of the tuberculins in the market and have reaped different results. Their strength varies according to their dilution and their source, and their use is not always wholly and uniformly reliable. To one conversant with the variability or strength in toxins of bacterial origin, it will be evident that to control a standard strength of antitoxin as exact as possible, one must

generate his own immunizing products. The necessity of this is enhanced by the fact that the bacilli of tuberculosis sometimes lose their virulence after certain generations and under certain conditions, and their alleged toxins are, consequently, absolutely useless. Therefore, after varied experiments and results we have abandoned the use of even the best commercial tuberculin except for experimental purposes and comparative studies, and we use only the products of home cultures of tested virulence.

It has been suggested by a few to use the ass or mule as superior to the horse for immunizing purposes. This is a mere fancy born on false therapeutic grounds and ignorance of the nature of these animals. Both the latter animals are by far more susceptible to certain microbic diseases than the horse. To glanders and certain other affections they succumb much more quickly, and to organic disease of the bones, skin and feet, they are frequent victims as compared to the horse. These maladies can not but make their serum more liable to dangerous results in man. On the other hand, there is no evidence to prove the superiority of the serum of these animals in any disease above that of the horse, which is generally much more healthy, and I believe the serum of the ass and mule less valuable because of their usually more pronounced natural immunity, and it is, as heretofore stated, the *acquired immunity* which produces antitoxin. In fact, one may try for months and fail to properly immunize the ass or mule. Similar failures sometimes occur in trying the horse.

The antitoxic property of the serum may be determined by its power to neutralize physiologically a given quantity of toxins of a given strength injected afterward in a rabbit or guinea pig, preferably the latter. A guinea pig weighing 500 grams dies within a certain number of hours when injected with a certain quantity of tubercle toxins of a certain strength from a culture of a certain age and kind, the exact details of which would require more time to explain and are not essential in a paper of this kind. Anti-tubercle serum that will neutralize this minimum fatal dose so that when injected it will not kill a guinea pig of 500 grams may be considered the unit of antitoxic value. But I can lay no rule on this question as yet. Our results are not definite enough or sufficiently uniform, nor have those of Behring, Maragliano and other investigators given as yet more satisfactory data. Owing to the variety of natural resisting power and natural immunity in the equine species, it will be at once apparent that the value of serum must occasionally vary also, and that much work is yet to be done to arrive at a uniform strength. However, with careful work one produces serum of generally uniform power. The European laboratories have accomplished nothing more than this as yet.

With respect to the use of serum in therapeutics, it is necessary first to test it on animals, in order to establish whether or not it contains the residue of the tuberculins used in the horse in producing immunity, or any other toxins. There is no chemie reaction known for this purpose. However, I may state here that these experiments, often repeated, have resulted in establishing the fact that ten days after the last dose of immunization no tuberculin remains in the blood of the animal, and, consequently, the serum separated therefrom is free from microbic toxins of this character. When, after some months of injection, the horse has ceased to react to the tuberculins for

some ten days of increased doses of toxins, it is considered immunized and capable of assisting nature in arresting tuberculosis. It is not as yet practicable to test each specimen of serum in tuberculous animals to establish its therapeutic value on Behring's mathematical law concerning antitoxin. For one reason it takes too long to get reliable results from tests on already affected animals. Behring has not himself as yet applied this law satisfactorily to tubercle antitoxin. We must depend on the knowledge that a certain number of days after the last reaction, and after the last immunizing dose, leave the serum with an average strength and a certain freedom from toxicity, which can be enhanced by laboratory processes and on the serum's neutralizing power in its action on tuberculin in small animals. It is to be hoped that the labors pursued in various parts of the world will, in the near future, establish a more positive method of determining the antitoxic value of anti-tubercle serum. So far, notwithstanding the unreasonable demands of critics, we must be content with the results obtained with immunized serum in clinics, as well as in animal tuberculosis. Various series of small animals have been under treatment and at the time of this writing some are still under treatment to decipher various points bearing on this question, but as yet we are not in a position to make any definite reports. It is not too much to say, however, at this stage of our work, that anti-tubercle serum is based on truly scientific grounds and has just as much right to exist and be considered by the profession as any other antitoxin, taking into consideration, however, the lesions existing in tuberculosis, which are quite different from those existing in other diseases treated with serum, with the exception of leprosy and syphilis. The serum for the latter two diseases is not estimated nearly as exactly as the anti-tubercle serum, and yet it is used in man.

The occasional charges that anti-tubercle serum is not well founded is childish. When human beings recover from consumption by the use of a remedy that does not harm, it is sufficient evidence of its scientific value to warrant its use, and it is manifestly unfair to try and dissuade one on any technical ground from considering it, particularly when nothing else can be offered to the unfortunate consumptives that has recoveries to its credit and improvements in even desperate conditions.

THE PROPERTIES OF SERUM.

Bearing on the whole subject of sero-therapy in any disease, we may profitably consider briefly the various properties, physiologic and therapeutic, ascribed to serum. The former consists of: The coagulating property, the toxic property, and the globulecide property.

The Coagulative Property. It has been established that the blood of one animal introduced into the circulation of another may cause an intra-vascular fibrinous clot, as has been proven by Héricourt and Hayem.

The Toxic Property. The serum in its natural state is often toxic and produces veritable symptoms of intoxication of different kinds, and fever, as I have often observed and mentioned before. Fortunately, most of these undesirable and dangerous elements may be prevented by proper treatment of the animals and the serum itself. One may add to this, the poisonous condition of serum after muscular exercise which is sometimes great.

The Globulecide Property (which produces oligocythemia and oligochromemia). The globulecide property of serum, of any kind, is a question of great importance in medical practice and little considered by the practitioner. It is a property which in large and carelessly administered doses may cause the destruction of thousands of red cells on being introduced in the system, and one which only technical experience can eliminate from the serum. This power may, in a few hours, according to the dose administered, reduce the red cells in the blood to the number of many thousands per cubic millimeter and prostrate patients fatally; but if the serum is given in very small doses at first and increased slowly, the diminution of red cells is imperceptible, and the increase is occasionally remarkable in a few weeks.

The therapeutic properties are as follows: 1, the bactericidal property; 2, the immunizing property; 3, the attenuating property; 4, the antitoxic property; 5, the stimulating property to organic defense.

The first named, the bactericidal property, which exists in certain serums is inconstant and can not be considered as possessing immunizing power, for it is destroyed, as explained by Dechaine, at 60 C., while the immunizing power remains at 70 C. Nor is the bactericidal property of a given serum a specific as a curative agent in a given germ disease, or as a force arresting the progress of a malady, because a certain degree of heat may destroy this bactericidal property and yet leave unaffected the so-called curative antitoxic property.

As to the third, the attenuating power, it was based on the misinterpretation of various results in experiments. It is now totally abandoned by the advanced laboratory technicians.

The fourth is the antitoxic (curative) power of which I have spoken above, the basis and understanding of which seem doubtful. It is very interesting now because the use of the word antitoxin so universally, has given origin to the belief that there can be produced in serum a chemie agent *capable* of destroying a bacterial poison.

Many have directed their efforts for years, in all parts of the globe, to establish the true chemie nature of the toxins and antitoxins, and all have failed. It is most difficult if not as yet impossible to establish facts relative to their chemie reaction when in presence of each other. But it has been demonstrated that while one may mix an antitoxin with a toxin in a test tube and inject thus with impunity a quantity of toxins that would be fatal if injected alone, a larger dose of the mixture always ends fatally. If a certain quantity of antitoxin could actually neutralize a certain quantity of toxins, a large dose of the mixture in the right proportions would not, by toxic effects, cause death. As has been pointed out, the venom of serpents being analogous to toxins and which can be rendered inoffensive in certain doses, otherwise fatal, by the mixture of antivenom serum in the same manner as diphtheria antitoxins, regains all its virulent power in the mixture when heated to 70 C., a temperature which destroys the serum but not the venom. This proves that there does not occur a chemie neutralization of the serpent toxin by the antitoxin. A serpent venom and a bacteria toxin are virtually identical. To what virtue then may be justly attributed the value of the so-called antitoxin in therapeutics? As already mentioned it is to the acquired force properly ascribed to serum known as the stimulating power

of the defensive cells of the organism. Without discussing this in detail, it may now safely be advanced on the results obtained by Metschnikoff, Gabritschewsky, Issaëff, Calmette, that immunized blood serum stimulates phagocytosis to greater activity, which results finally in destroying the microbes. The cells probably destroy the toxins in their interior by the action of cellular diastase.

THE EFFECTS OF SERUM IN TUBERCULOSIS.

Since the beginning of our clinic tests of serum in tuberculosis, we have treated many different kinds of tuberculous processes. Tuberculous affections of the throat, lungs, joints, bones and bowels have been treated with this agent exclusively, pulmonary consumption of all varieties constituting the greatest number of the cases. We will consider, briefly, pulmonary tuberculosis.

This disease is the most prevalent form of tuberculosis, and, remarkable as it may appear, it seems to be the most frequently unrecognized and the most commonly misjudged condition until it is *too late* for human intervention to even arrest the progress of the disease. This is not so strange, however, when we consider the past, and even the present, erroneous and careless clinical teachings in many quarters of the land. The diagnosis of this malady and certain other diseases of the chest, which so easily confuse the physician's ear and mind, do not always receive sufficient attention. To begin with, the pathologic conditions of the lungs due to, or complicated by, the bacilli of tuberculosis alone or aided by other microbes are insufficiently weighed by the majority of physicians and too often grossly neglected by medical teachers in certain schools, too absorbed in their clientele to have time for exact clinical investigation and teaching. In the next place, the careless tendency to classify (either to please patients or to shift the grave and unpleasant duties), apparently trifling but really serious symptoms under the head of bronchitis, or the misleading name of catarrh, without proper investigation or observation, is too extensive. In the third place, there is too little exactness in the meager investigations usually made, bearing on the history of the patients, and as a result the beginning of the lung disease is often dated by the physician months or years after its true incipency. The pathologic condition, which after examination of patients is termed incipient, is frequently in fact passed beyond the first or even the second stages. Indeed, I have seen tubercular unfortunates almost at death's door declared in the early stage of consumption by men of reputation. Finally, the exact nature of the lesions existing and the complications are not always given sufficient attention. As a result of this prevalent carelessness in diagnosis, the forms of treatment are faulty and the results thereof disappointing and discouraging. Patients are held under treatment for bronchitis or trivial affections for months, years, and sent away at last to some other climate to die of consumption. Or they are dosed with cough syrups, cod-liver oil and various nostrums, irrespective of conditions, until irremedial lesions are formed.

On the other hand, consumptives often seek professional advice only after irremedial lesions have been established. In our clinical experience *not a single case of incipient tuberculosis* brought to my notice have I had the opportunity of treating with the serum. More than 75 per cent. of all those who have honored me with their confidence more or

less completely, were in advanced disintegration locally, advanced prostration and emaciation generally, had tuberculosis dyspepsia of the gravest character, and many of them in fact were practically moribund. Desperately ill, often with desperate cavities, lung contractions, and lung tissue transformations, wrecked nervous systems, the unfortunates grasped the proverbial straw of the drowning man. It is chiefly from such hopeless cases, some of which are referred to me by physicians, as favorable and typical, that the results of sero-therapy have been established or criticized in my own clinical work, as well as in that of most other physicians, and many are to-day attacking sero-therapy from this basis. Not one case of chronic tuberculosis of duration shorter than one year from the real incipency has been treated by sero-therapy to my knowledge, and yet, to my amazement, I find myself confronted by uncomplimentary remarks on sero-therapy in tuberculosis by medical men, considered competent, solely because of the failure of serum to cure moribunds, even after improving sometimes their weight and strength temporarily, which no other treatment has accomplished. Evidently there is a disposition to make it appear that a treatment of consumption must either accomplish miracles or must be considered as valueless.

This unwarranted position assumed by a few prejudiced persons, is evidenced by the efforts made in certain quarters, to depreciate sero-therapy in tuberculosis by proclamations of the number of deaths during this treatment, knowing well, or ignoring from lack of experience and medical knowledge, that no remedy can ever cure the class of tuberculous conditions in which the equilibrium of nature is utterly lost by virtue of irreparable lesions or constitutional disturbances. These efforts are unfair and small in the minds of broad-minded people. The effects of serum are not mystic or magic. They must be considered on the broad basis of physiology and pathology. It is a great injustice to patients and investigators alike, to reject any treatment of so hopeless a disease as consumption, simply because desperate cases can not be resuscitated.

That serum in any disease is entirely harmless is a fallacy, and that it is very dangerous is also a mistake, and that it has its advantages and disadvantages must be recognized by every physician who conscientiously practices medicine.

As I have said, it is well established that serum is globulecide. It destroys the red blood corpuscles to some degree if suddenly given in large doses, particularly if injected into the circulation. Hence the damage that may be produced on account of this effect, and the occasional death by collapse when the disease (diptheria, say) has subsided. In tuberculosis if the serum is injected in animals or man in very small doses to begin with, say 0.5 to 1 c.c., once a day, for a few days, and then increasing very gradually to 5 c.c., and even to 10 c.c. per day, according to the results, the ultimate effect, with few exceptions, is usually not only to increase the quantity of the red cells but also to increase the strength and avoirdupois of the individual. In exceptional cases a feeling of depression occurs from the first days of injection and gradually increases. These, usually observed among the anemic, are unfavorable cases for sero-therapy by hypodermic injections and should not be kept under it, unless applied per rectum.

On the other hand, the white blood corpuscles

increase enormously, hence the *increased power of phagocytosis which is the curative force in microbial affections*, but which, in tuberculosis can not be independent of the sustenance of the red cells.

The untoward local effects of serum injections for any disease are now fairly known. Erythema, exanthema, cellulitis, myelitis, articular pains and swellings, sero-infiltration of the connective tissue about the eyes, etc., have been noted by most observers on sero-therapy and are mentioned above. Beside this must be mentioned the occasional appearance of albumin in the urine. In tuberculosis I have observed before treatment, albuminuria more or less pronounced, without casts in about 11 per cent. of the cases examined in the last twelve months. Under sero-therapy the quantity of albumin did not increase except in two cases. On the other hand, I noted transitory albuminuria appear in three cases out of thirty-six, where it did not previously exist, but with no ulterior bad results.

One rare but alarming symptom that has occurred to me and others in sero-therapy is a sudden flushing of the face, apparently a serious disturbance of the vaso-motor system. It is seemingly due to some elements of or in the serum albumin as various tests to modify or extract this substance leaves the serum free from such a property. It has never proved serious in the fifty-odd thousand injections of anti-tubercle serum in human beings.

VARYING NATURE OF PHTHISIS, WITH RESPECT TO TREATMENT.

A fact singularly overlooked in medicine is the "unity without conformity" which exists in pulmonary consumption. While all forms, at a certain stage, present symptoms in common, which are sufficient for a proper diagnosis, the lesions are often very different and the prognosis should be made accordingly. A dozen pathologic conditions may be found in pulmonary consumption: White granulations; yellow granulations; gray and dark granulations; gray infiltration (or catarrhal pneumonia); red hepatization; fibrinous nodules (blood residues); fibrosis; cretaceous masses; cavities; vesicular emphysema; tubercular pleurisy; complications of laryngeal tuberculosis; mixed microbial infections and perhaps others. These different conditions have varying importance, as well as have the degree of their existence in areas and intensity and the stage of the disease. With respect to constitutional changes, it is not logical, therefore, to expect uniform results in all forms of tuberculosis at any stage—each case must be treated on its merits. It is idle to expect sero-therapy or any other kind of specific therapy to arrest progress as easily, if at all, in a chronic case with contracted tuberculous lungs as in a case of acute tuberculosis with infiltrations. In each case there is a loss of vital capacity by virtue of lung alteration precluding the air from penetrating more or less extensive areas of obliterated lung tissue and oxygenizing the blood. In each case there may be high fever due to mixed or unmixed toxins manufactured in the morbid areas and absorbed by the circulatory system, but the patient with a contracted lung can scarcely ever hope to recover his health and can surely never have the transformed tissue restored to proper lung tissue: while the patient with lungs filled with the products of acute tuberculosis, as fatal as this disease has been heretofore, may sometimes be restored if treated before the breaking down of tissue.

In therapeutics, it is essential then to pay proper attention to existing pathologic conditions of the lungs before attempting to make a prognosis or to prescribe. As to mixed infections, they are so common in all forms of pulmonary tuberculosis, the question must always be present in the mind of the clinician.

I had hopes of touching on some of the numerous forms of tuberculosis in other organs than the respiratory apparatus, but my paper is already too long. I wish to state simply that in all of these, there may and there does usually exist at a certain stage, microbial complications of serious nature which must be considered and treated by special processes, which no specific treatment of pure tuberculosis is supposed to reach properly.

With these observations in mind, let us consider the results in one hundred cases treated by myself and others by the use of serum. In these you will see quite different results, according to the classes to which they belong, respectively. Some of the failures, as unavoidable as they must have been, in the hand of human beings not endowed with omnipotence, have been selected by certain physicians as evidences of the inefficiency of sero-therapy in tuberculosis. I condone nothing, I give you our success and failures.

REPORT OF CASES.

In the following report of cases treated in the last fifteen months exclusively by the use of serum, I mention partial improvements and failures as well as recoveries. But space and time fail me to give a detailed explanation of every case in the paper. In reading this report, one should take into consideration the stage of the disease and the lesions. Results must vary according to the nature of the disease and whether it was accompanied by high fever, extensive infiltration, etc., or whether the third stage or even what may be termed the fourth stage, had been reached with such conditions as cavities or contractions of the lungs or other pathologic phenomena demonstrating beyond a doubt that the disease had been existing a long time and altered the tissues of the organs affected beyond repair or had produced irremedial constitutional changes.

ACUTE TUBERCULOSIS.

Miss V. Z., East St. Louis, Ill., physician in charge Dr. J. L. Wiggins, East St. Louis, Ill. Consultants, Dr. J. R. Lemen, St. Louis, Mo., and myself. Miss V. had been ill several months and the last weeks previous to consultation she had been prostrated in bed with a complete history of acute pulmonary tuberculosis. The range of temperature was between 103 and 104 continually for many weeks prior to treatment. The one microscopic analysis made by us demonstrated the bacilli of tuberculosis. Each physician consulted diagnosed acute tuberculosis. Every ordinary method of treatment was pursued and the fever remained at 104 and even reached 105, with symptoms of delirium, etc. On auscultation and percussion, it was found that the lungs were both largely involved and infiltration was nearly complete in one. Dispnea was excessively pronounced, weakness extreme. Prognosis fatal. Everything having failed, it was decided, after consultation between Drs. Wiggins and Lemen, to try the serum which I produce. The treatment began, I think, on June 9, 1895. The dose ranged between 20 and 40 ms. daily, and continued some six weeks more or less regularly. The result was that the temperature decreased gradually and steadily after seven days' treatment to normal temperature, which was reached on June 22, or thirteen days after the first injection. Injections were continued until the end of July. The patient gradually picked up, gained strength and flesh and is again at work. Her occupation previous to her illness was that of an actress. Since then she has been engaged in various pursuits in a clerical way and is said to be healthier than before. She weighs 132

pounds, whereas she was emaciated to at least 80 pounds before treatment. The germs of tuberculosis have disappeared entirely and every symptom of lung trouble is absent.

R. C. G., St. Louis, Mo., aged 65 (?); Dr. Simpson was physician in charge; three consultants. Diagnosis of all was acute tuberculosis or tuberculous pneumonia, which was evidenced by acute pneumonia with almost complete infiltration of the left lung and extensive infiltration of the right. Prognosis, fatal termination. The patient at the beginning of treatment weighed between 150 and 160. Serum was continued about three months more or less regularly every day, after which it was administered irregularly for about two months. This patient suffered, before the beginning of treatment, with imperfect kidney secretion, and had to be injected with care accordingly. The microscopic analysis of the sputum was made first. I was assured, by Dr. Ravold, bacteriologist of the city board of health and of the St. Louis Medical College, and later by Dr. George W. Cole, of the Woman's Medical College, my brother, a chemist, and myself at the St. Louis Sanitarium before and at the beginning and during the course of the treatment and in every instance, until after some weeks of treatment, the bacilli of tuberculosis were found in quantities more or less profuse. The patient received injections of serum almost daily in doses varying from 10 to 40 ms. for about three months, and irregularly thereafter for a month or two more. At the end of three months no bacilli were to be found in the sputum, and repeated analyses made by the same analysts failed to reveal them. I am sure they are not to be found now. The patient, who was at the beginning of treatment in bed, picked up in flesh rapidly and at the last date upon which I saw him, in the month of December, weighed over 200 pounds. He is now traveling, visiting his children, and reports splendid health. There remains, however, in this case a pleuritic adhesion on the left side which is probably a permanent cicatrix lesion, and possibly of a fibrous transformation in the lower lobe of the same lung. This patient exhibited before and during treatment, and does yet exhibit to a slight degree, symptoms of asthma. He has returned to work and is able to attend to his duties as real estate broker and feels perfectly safe and happy.

Mrs. F., San Antonio, Texas, practically the same kind of a case as Miss V. Z., the first patient reported above, and the success was the same. She is well to-day.

These are the only three true acute cases of pure tuberculosis that have been treated with the serum to my knowledge, all three responding alike and are well to-day.

CHRONIC TUBERCULOSIS.

It is obvious that it is exceedingly difficult to establish an arbitrary line between the first and second stages and the second and third stages of pulmonary tuberculosis. Whoever may hear me or read this might for convenience sake include in the first stage all those whose conditions have not broken down the tissues or produced a marked constitutional depression or infection. This does not include incipient tuberculosis, which is earlier still and seldom brought to the physician, and far less the pre-tubercular conditions which the doctors seldom see. The second stage is exceedingly grave and other stages may be classed as usually hopeless and beyond remedy.

Mrs. H. R., St. Louis, Mo., consulted me in February, 1895. Her history was that she had had slight hemorrhages, had been ill for two years, had coughed and was coughing very severely and had expectorated previously a muco-purulent material, occasionally tinged with blood. The sputum at the time of examination was full of bacilli of tuberculosis and largely loaded with different forms of pusgerms. Her attending physicians kindly acquiesced in her desire to try the serum. Mrs. R. at the beginning of treatment evidenced infiltration in the apex of the right lung between the third and fifth rib, covering an area of about four inches laterally and penetrating the lung, more or less through and through from anterior to posterior. There were mucous râles about the middle of this area, very pronounced, and interrupted breathing on both sides. The circulation was exceedingly rapid and fever ranged usually from 98 to 101.25, rarely it went above that. The patient had night sweats, had lost much flesh, being reduced to the weight of ninety pounds. During the first two or three months of her treatment there was illness in her mother's

family, in which a brother died of tuberculosis, and illness in her own family, one of her own children being confined to its bed several weeks, all of which conditions precluded Mrs. R. from getting sufficient rest and peace and nourishment, and all of which forced her to an excessive amount of worry and annoyance and labor. Notwithstanding this, however, on the regular dose of 30 ms. a day for three or four months and then irregular treatment every second, third or fourth day, with a loss of three weeks at one time, covering a period of six months all told, Mrs. R. improved in flesh to the weight of 132 pounds, and became strong accordingly, developed a splendid appetite, and for the last three months her sputum, which is exceedingly scarce now and comes only when she is affected by cold, exhibits no bacilli of tuberculosis. She suffered a miscarriage and six weeks illness recently, but her lungs remain apparently sound. The physical lung symptoms which existed at the beginning have disappeared, and so far as I can judge the patient has recovered.

Mr. E. D., St. Louis, Mo., age 36, occupation shipping clerk; history of glandular tuberculosis dating back eleven years. Had pneumonia four years previous to his examination in my office, May 16, 1895. Had been declining six months, had night sweats and fever, pain in left lung, back and front, pulse 108 at time of examination: abnormal temperature ranged from 99.3.5 to 101: coughed chiefly in the morning: expectorated a yellowish matter: slept fairly on the right side but could not sleep on the left side because of pain in the chest: was too weak to attend to his duties. There was marked dullness in the left lower lobe and crepitus of the left apex over a lateral area of four inches, extending about three inches downward, interrupted breathing, both sides. All these symptoms disappeared almost entirely in four months of treatment consisting of 15 to 30 ms. of serum a day. Examination of the sputum made since revealed no bacilli. Mr. D. is at work from twelve to fifteen hours a day, Sunday included, and feels strong and in good health and so far as can be judged by the absence of symptoms enumerated, he has recovered. He did not bear injections of serum well, being often upset, but he persisted and recovered.

Mr. F. S., St. Louis, Mo., came to me to be examined in February, 1895. He weighed about 145 pounds at the time. Had had very profuse hemorrhages at Hot Springs and was sent home considered hopeless; had lost about fifty-five pounds from his regular weight, which was above normal for his size: was coughing a great deal night and day: expectorated a thick, yellowish matter loaded with bacilli of tuberculosis and other microbes, and was rapidly declining and weakening. He was unable to perform any of his duties as a groceryman. His physical condition evidenced tuberculous affection of both lungs, particularly in the right, over the whole of which interrupted breathing was very plainly perceptible with loud rumbling. The lower half of the lung exhibited moist râles. The left was slightly involved in the same manner. These symptoms after seven months of more or less regular treatment, which consisted of 20 ms. in the beginning and was increased to 30 and 40 and once in a while to 60 ms., almost entirely disappeared with the exception of a slight interrupted breathing. Flesh was regained to the amount of 170 pounds and strength seems to be as good as ever. Mr. S. is now and has been for four months attending to his usual duties, working hard every day and complains of nothing. He expresses the opinion that he is free from disease. In this case there was a slight cavity formed and expectoration has not entirely disappeared, and once in a while bacilli of tuberculosis are found, and yet his condition of health seems to be generally improving, and in my judgment, his condition has been arrested by the serum and is held at bay by it and the assistance of natural forces. I will have occasion to refer to this case again, inasmuch as health seems to be restored and the bacilli of tuberculosis are still present, which seems to sustain the idea that anti-toxins do not kill germs but chiefly neutralize the effects of the results they produce by increasing natural forces.

Mr. F. B. M., St. Louis, Mo., age 20; occupation railroad clerk, working at night: had had bronchitis at the age of 14: had suffered from night emissions from early puberty. Previous health feeble: cough scarce; pain in the lower lobe of the left lung; temperature 99 to 100 F. Physical examination evidenced dullness of the lower left lobe beginning at a line drawn below the nipple and extending down toward the base. Microscopic examination revealed the bacilli of tuberculosis not in large numbers. Mr. M. was treated from May 27, 1895, to the middle of September, practically four months. All physical symptoms and evidences of tuberculosis have disappeared. He is now at work as before and apparently in good health. No bacilli have been found in the examinations made since.

Mr. G. N. F., St. Louis, Mo., was examined April 29, 1895;

age, 45; occupation, bookbinder. Had had a dry hacking cough two years: had had pneumonia at age of 18: congestion of lungs two years previous to his examination. Feb. 7, 1895, he had hemorrhages which dragged him to bed, and at the beginning of treatment he weighed 130 pounds: expectoration thick and yellowish: bacilli of tuberculosis numerous. Temperature 99.3.5 to 101 and 102: infiltration of the left apex below second rib about three inches downward and four inches across, evidenced both anteriorly and posteriorly: dullness over same region: crepitus over some of the area and râles and crackling on deep inspiration extending below left breast anteriorly. Mr. F. was treated with tubercle antitoxin from the beginning of May until the beginning of October, almost every day at the dose of 30 to 40 ms. Since then several examinations have been made and no germs of consumption are to be found. On the other hand, physical symptoms had at the time of my last examination practically all disappeared and there is little, if any, expectoration whatever. The patient has resumed his work and considers himself cured and I consider the disease arrested. He weighs to-day 140 pounds, which is more than his normal weight before his illness. He has been attending to his usual duties several months.

Miss S., Nashville, Tenn., was admitted to the Sanitarium in May, 1895, and remained there under treatment some three months. She came with a written diagnosis of pulmonary tuberculosis from her family physician, which was substantiated by microscopic and physical examination. The bacilli of tuberculosis were found in large numbers and the patient was rapidly losing ground both in weight and strength, coughing considerably, particularly at night, and expectorated occasionally a yellowish matter and sometimes a greenish matter. Night sweats had existed and fever ranged from 99 to 102 F. She was treated with serum at doses ranging from 20 to 30 ms. After three months she had gained ten pounds. She then migrated to Las Vegas, N. M., where she continued the treatment, and her improvement continued. She, at first, lost flesh there, but again increased and every vestige of symptoms seems to have disappeared, if I may judge from the reports sent me. The bacilli and all physical signs of lung disease have disappeared. Bacilli have not been present for over two months. The disease in Miss S. is considered arrested, I judge, by her attending physician and she considers herself cured.

Miss G. A., St. Louis, Mo., age 19 years; occupation, music and vocal student: had had influenza in Memphis six years before, dry cough for a year: weighed 123 pounds; hemorrhage four years previous to examination, Sept. 26, 1895; larynx infiltrated: temperature from 99.5 to 101: coughing considerable and expectoration in the morning of a yellowish matter. Bacilli of tuberculosis quite numerous. Heart disease evidenced by regurgitation. Treatment began the last day of September, 1895. Injected very small doses on account of her heart condition, that is, 10 to 25 ms. daily. At this time Miss A. weighs 135 pounds. The bacilli of tuberculosis have disappeared. For two months there was but one or two in the field of bi-monthly examinations. Cough has almost entirely disappeared. Strength has been regained and appetite is splendid. This patient is considered as having almost if not practically recovered, as there exists no longer the physical signs of infiltration, and the first signs of breaking down which existed at the beginning of the treatment are absent.

Mrs. N., Chicago, Ill., age 33, has a family of six or seven children; began treatment at the Sanitarium May 19, 1895, and continued at the institution under the treatment for a period of two months, at which time she went away and later reported as being free from disease, her expectoration having ceased and her cough being *nil*. This patient had been ill two years, had had pneumonia, following an operation for hemorrhoids. Having had no opportunity of making an examination since this report I am unable to verify it with personal data.

Mr. V., employed at our institution, a patient under the charge of Dr. L., had laryngeal tuberculosis and pulmonary tuberculosis. His condition had been declared, in writing, hopeless by a number of specialists in St. Louis, including all the leading ones. He has been treated under the special care of Dr. L. and occasionally myself for a period of about ten months, having received from 30 to 120 ms. a day. At the beginning of his treatment there existed infiltrations of the larynx and other lesions: he had lost his voice, weight and strength. He was in a hospital, unable to perform any work. He is now assisting in the care of some twenty-two horses in company with another man, working many hours every day in water and dust, and his appetite has improved and his strength keeps good. He is sensitive and susceptible to colds, but under the treatment of serum he had gained a condition which permits him to do all the manual labor that can be asked of almost any man. Rarely

have we found bacilli in the scant expectoration during the last four months. I am unable to say more of this case because of the fact that he is not a patient of mine and I do not see him regularly. I report him because he is under my supervision and the injections are done by my assistants or myself. The case is surely under control at present. Some physicians pronounce him practically cured.

Mrs. A. C., age 26, married, has had three children and two miscarriages, one recently. At the age of 12 she received a kick in the chest, at which point pain appeared frequently and whenever the patient contracted cold. At her examination infiltration was discovered over an area of about three inches in diameter on the right side below the breast, also a dullness in the left lung between the second and third ribs, extending about two inches downward and about two inches laterally. She had had the various symptoms of tuberculosis for some years and dated the accidental incipency of it fourteen years previous when she had received the kick at a spot where the consolidation occurred. She had had several hemorrhages. The active development of the disease dated three years previous to my examination, which occurred June 7, 1895. At that time she weighed 115 pounds, to-day she weighs 135 pounds. She had dyspnea, expectorated a great deal, coughed almost incessantly, had a very poor appetite. Now all these symptoms have disappeared and her strength has increased so that she is able to perform her daily duties. She comes to my office almost daily and expresses herself as improving continually. The physical signs above mentioned have disappeared to a considerable extent, although not completely. Pleuritic lesions exist beside the consolidation mentioned. Bacilli of tuberculosis have been found but once in very small numbers in the last three months and this was long ago.

SURGICAL TUBERCULOSIS.

B. McG., age 18 years 2 months, had been suffering with joint and bone tuberculosis for seven years and had ten operations performed on different parts of his body to open abscesses and to remove necrosed bone. The seat of the primary trouble was the right hip-joint, but was giving him trouble on every limb. The left tibia was much involved, having at one time eight openings discharging tubercular pus. The hip had three openings that would heal and open alternately and one that was open continually for seven years. He had an abscess on each arm, one of the sternum, one of the index finger of the right hand, a tubercular nodule in the skin of the scrotum, an abscess near the apex of the left scapula and two on the lower jaw. The patient says that after the continued efforts of Dr. J., of Waverly, Ky., who had as consultants, Drs. H., of Henderson, Ky., and A. J., of Sturgis, Ky., to cure the patient had failed, it was decided to let nature take its course. He was without medical aid for two years. In the fall of 1894 he was put in care of Dr. Broome, St. Louis, who performed an operation to remove necrosed bone from the thigh and tibia, thinking that these openings would heal. This having failed he decided to try the serum treatment and was taken in charge by Dr. G. W. Cale, St. Louis, Mo. He began the treatment in March, 1895, at which time he had four abscesses discharging a characteristic tubercular pus and two others that afterward opened. He had daily injections of serum in doses of 20 to 30 ms. and at the close of six months' treatment five of these abscesses had closed, he had gained ten pounds and was without temperature. He is working steadily and is still gaining weight. The last and only opening, a very slight one, is on the thigh and dead bone (to be soon removed) has been located which is the cause of its remaining open. Up to the present date he has gained sixteen pounds, has a good appetite and is enjoying good general health.

In every one of these cases the diagnosis was based on careful physical examination and microscopic analysis and there was no mistake made. I may add to this record of good results:

Mr. K., pulmonary tuberculosis eight years, in last stage of the disease; cavity in one lung; contractions and infiltrations in tissue. Had been injected three months in vain with tuberculin; gained over twenty pounds with serum and all symptoms have so improved that he has returned, in part, to his work as insurance solicitor. He was treated eight months almost daily.

Miss H., stenographer, had been invalid two years; disease in second stage; regained ten pounds and about normal strength in four months and to day seems to be on the high road to recovery.

Mr. M., grain dealer; disease in third stage; increased eight pounds and in strength, and is enabled to keep to his work by continual treatment.

Mr. W., printer, disease in the second stage; increased over ten pounds and exhibits no bacilli and has exhibited none for three months.

Mr. O., stationary engineer, was ill several years; exposed to alternating heat and cold; disease in the third stage; treated seven months; regained his strength sufficiently to keep up his arduous duties, which he must have abandoned long ago.

Of the twenty-two City Hospital cases reported a year ago, I have been able to keep track of but two. Most of the others scattered after leaving the hospital improved. One with a cavity, extensive infiltrations, adhesions, displaced heart, was raised from bed, increased thirteen pounds and returned to work in six months during the exclusive use of serum. He then died suddenly at the City Hospital after a liquor debauch and I did not have the opportunity to see the post-mortem examination. The other, a case of over three years, Mr. H., with advanced tuberculosis, was likewise raised from a bed of sickness over a year ago and has almost ever since been working as a stable man and seems to be fairly healthy and strong.

I might add to this series of improvements a number of others in a more or less serious condition who are still under treatment by the exclusive use of serum, but besiring to report no case too early after positive improvement, I will abstain from mentioning them specifically until later. I might add, too, a number of desperate cases, among which a few were benefited temporarily. Probably all such cases, and the cases with large cavities, with a history of long standing tuberculosis will succumb. It is usually in the last stage that patients submit to new treatments for consumption, and it is often in the same stage that doctors are willing to try new remedies of this character. These unfortunates (with contracted lungs, large cavities, hopeless transformation of tissue, general infection, etc.) who grasp at this treatment as a last resort, can hardly be expected to recover permanently, although some of them do improve, and in a few the disease seems to be checked. In my practice, I do all in my power to prevent hopeless cases from using the serum, although it is not unfair to try and prolong their life with it, if at their own request, understanding fully the consequences, they demand a trial. The injustice of discrediting the value of serum on the results obtained in such cases is obvious to any unprejudiced and fair minded man.

In conclusion I will state that of one hundred cases of pulmonary tuberculosis treated from three to eight months, during a period of fifteen months, the following results have been obtained:

In the first stage, treated, recovered and discharged, 14	
In the second stage, improved, in statu quo, or still improving or checked (including thirteen who returned to their duties after having been considered hopelessly ill and near their demise)	26
Disappeared from observation in all stages	35
Died: treatment begun in second stage	5
Died in the third and fourth stage, including ten practically moribund, who insisted on trying the treatment	20
	100

Thus the recoveries in the early stages have amounted, so far, to 100 per cent.

Penalty for Criminal Malpractice. A new though practically amendatory section was introduced into the criminal law of Missouri in 1895 which provides that every person who, without intending necessary medical or surgical treatment, and without intending other injury than the destruction of pregnancy, shall kill any woman by administering to her any medicine, drug or substance whatever, or by using upon her any instrument, or other means for the purpose of destroying pregnancy, shall be guilty of manslaughter in the first degree.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

REPORT OF THE COMMITTEE ON SYLLABUS.

CHICAGO, Feb. 15, 1896.

A committee was appointed by the secretary of the Association, Dr. Perry Millard, on each of the branches of a medical curriculum in 1894. These several committees made reports which were presented at the meeting of the Association at Baltimore, May 7, 1895. The several reports were referred to a committee consisting of Drs. Perry Millard, Howard A. Kelly and Bayard Holmes, and ordered printed.¹ On account of the various standards used by the several committees, it was found impossible to coordinate this work so that a well-balanced course of study could be recommended. Therefore during the past year a plan was formed by the present secretary for the study of medical education in conferences. The work was laid out so that each conference would have a special part of the curriculum to consider.

In order to call together representative men and educators ten institutions were requested to send delegates to the first meeting. The call was addressed as follows:

My Dear Doctor.—The Association of American Medical Colleges has now arrived at practically the following condition of things: Nearly half of the medical schools in the United States are members of this Association, and more than half of the schools in which regular medicine is taught.

All members of this Association will hereafter require four years of attendance for graduation.

The minimum year of schools in this Association will consist of six months, the average year of eight months and the maximum probably of nine months of actual study.

The entrance requirement is now fixed at the minimum, equal to about the second year of the ordinary high school course, and that requirement will probably soon be equal to the average requirements for admission to the literary department of colleges and universities.

The amount of study which any student of a medical school can be reasonably expected to do is fixed by pedagogic experience, and is four recitation hours a day, requiring each about an hour and a half of study for preparation.

It is very desirable in this formative period of education that the discussion cover the most desirable course of study, the most desirable methods of presenting each branch and the most desirable methods of testing the attainments of the students and giving them credit for their work.

Therefore the secretary of the Association of American Medical Colleges, with the consent of the President and Judicial Council, hereby calls upon the colleges to furnish representatives to a number of committees, to meet at suitable points and on suitable occasions to discuss these subjects and present a combined report at Atlanta next May. On account of the number of subjects he proposes to divide the curriculum into three groups.

Group 1 will be composed of all those branches that treat most exclusively of the normal human body.

Group 2 will consist of all those branches which consider most exclusively the diseased human body.

Group 3 will consist of all those branches which deal with the treatment of the diseased human body and the prevention of disease.

Three committees will be appointed, each consisting of as nearly ten persons as possible, one committee for each of these groups. Each committee will discuss the following topics: 1, the amount of time and the amount of work for each branch in this group; 2, the place in the four year course in which each branch in this group should appear; 3, the particular work required in each branch and the amount of work allowed to be elective; the particular work suggested by the committee as most desirable out of which to fill up the elective portion; 4, the methods by means of which each of these branches should be presented to the students; 5, the methods and means by which each student should be tested and given credit on each branch.

In order to begin this work the committee of ten upon Group No. 1, in which will be found anatomy, physiology, histology and embryology, is hereby called to meet at the Palmer House upon Saturday, the 15th of February, 1896, at 9 A.M. The University of Minnesota, the University of Michigan, the University of Iowa, the University of Wooster, the Lake Forest University, the Northwestern University, Cincinnati College of Medicine and Surgery, Columbus Medical College, Detroit College of Medicine, Fort Wayne College of Medicine, are requested to send each a representative, to remain in the city three days at least, and hold a continuous meeting until the work is finished.

If your institution will cooperate in this work be kind enough to inform me by return mail and suggest the person whom you wish to represent your university upon the committee.

Trusting that I may hear from you by return mail, I am,
Very truly yours, BAYARD HOLMES.

The conference convened at the Palmer House at the hour mentioned with the following representatives present:

W. S. Hall, Northwestern University; W. E. Lewis, Cincinnati College of Medicine and Surgery; A. P. Ohlmacher, Wooster University; C. B. Stamen, Fort Wayne Medical College; Bayard Holmes, College of Physicians and Surgeons, Chicago; J. E. Brown, Ohio Medical University; W. D. Middleton, Iowa State University; H. O. Walker, Detroit College of Medicine; W. O. Gross, Fort Wayne Medical College; Thomas G. Lee, University of Minnesota.

The conference was called to order by the Secretary of the Association and the plan of conducting the business decided upon.

As a preliminary step to the arrangement of a curriculum the committee considered it expedient to recommend the use of certain terms in a more or less technical sense, thus avoiding misconceptions and facilitating the expression of ideas on the subject.

The Recitation Period.—A recitation period is the time occupied by the student in the preparation and recitation of one lesson. The time spent in a recitation is nominally one hour, and usually a topic assigned for a recitation requires about one and one-half hours of outside preparation. Let the expression "recitation period" be understood to mean two and a half hours' work. From this it is clear that a laboratory exercise requiring two hours of laboratory work and one-half hour of outside reading and preparation of notes is equivalent to a recitation period. Further, each didactic lecture involves, or at least should involve, a parallel course of supplementary reading assigned by the lecturer. In order to introduce uniformity into all the courses let it be understood that the assigned outside study accompanying a lecture course be equal to one and one-half hours for each one-hour lecture. In the same way a two-hour clinic should be made to consume in the aggregate an extra half-hour of work, either in reading up parallel cases, in taking and recording of histories or in the examination of pathologic material, for every two hours of actual work in the clinic.

By thus putting all work on the basis of the recitation period of two and one-half hours, the work of arranging a typical curriculum is much facilitated.

As to the number of recitation periods which should constitute a week's work, the discussion brought out many arguments. In the first place the medical colleges of to-day are for the most part the evolved product of those of yesterday when a year's work was crowded into five or six months, and a whole medical course into two or three of these short years. Under the earlier conditions as much as seventy-five hours of

¹ Report of the Committee on Syllabus, JOURNAL AMERICAN MEDICAL ASSOCIATION, June 29 and July 6, 1895.

mental work, 30 recitation periods, was accomplished by the diligent student in one week. But the extension of the course of study to more than three times its original length has not been accompanied by a sufficient relief of the tension of work to admit the student of average strength to carry the course without manifesting signs of overwork. Most literary and scientific colleges require from 14 to 16 recitation periods per week of each student. Most medical colleges require from 20 to 30 recitation periods per week. The committee agreed that because of the greater maturity of students in medical schools, and the fact that a larger proportion of the work is "low-pressure" work, in laboratories and clinics, medical schools are justified in requiring 20 recitation periods per week. This represents fifty hours of work per week for the student. It is recommended that as far as may be these 20 periods be assigned to five days with 4 periods each. Somewhat more work than this may be permitted in special cases.

What shall constitute a year of work? Most of the institutions belonging to the Association of American Medical Colleges have seven or eight months for a year's work, a few have only six, while others have as many as nine months. The committee agreed, that their work would be most useful if they based their recommendations upon a year of thirty weeks, of 20 recitation periods each, or an aggregate of 600 recitation periods. A college having only six months (twenty-five weeks) could attain about the same aggregate by requiring 24 recitation periods per week, while a college having nine months might well reduce the required number of recitation periods per week to 18. Such a reduction of quantity would naturally be accompanied by an improvement in the quality of the students' work.

Another very convenient expression is the term *year hour*, which is defined as *one recitation period per week throughout the year, or 30 recitation periods*. But the number of recitation periods would depend upon the length of the year in any particular institution and might be 25 or 36 according to the length of the year. In any case the number of year hours multiplied by the number of recitation periods per week should equal 600 recitation periods.

It was further concluded by the committee expedient to divide the year into a Winter semester and a Spring semester of 300 recitation periods each.

The committee then considered the division of the four years of study now required by all members of this Association among the branches of study which it considered should be contained in the medical curriculum. This necessitated the consideration of the preliminary education of the student and the required and elective work.

It was assumed that the students of our institutions are fully up to the requirements of the Association and possess a good knowledge of English, a thorough training in arithmetic and elementary algebra, a thorough training in elementary physics by the laboratory method, at least two years' work in Latin; but that they have had in a majority of cases no preliminary training in chemistry or biology.

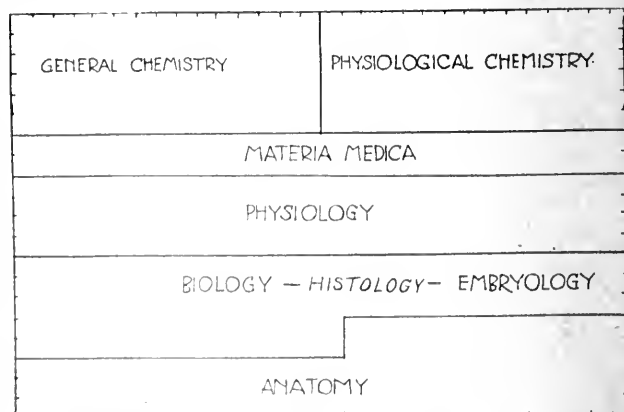

In preparing students for medical study teachers should aim at a serviceable knowledge of English and English literature and a definite command of the English language in composition. Thesis work on topics with which the student is engaged should be strongly insisted upon, and every attention should be paid to forms necessary for the guidance of the printer.

The work in arithmetic should be so thoroughly completed that it would become an unconscious tool in the mind of the student, and it should be combined with a thorough knowledge of the metric linear, square, cubic and liquid measure and with the metric weights. The algebra should be sufficient to cover simple and quadratic equations. The course in physics should be much more extensive and thorough than that proposed by the committee of ten on secondary school studies, and published by the Bureau of Education (pp. 25, 26 and 117-127). It should be a careful course in experimental physics in which the student should prepare his own apparatus, conduct his own experiments after such a plan as that outlined in John Trowbridge's "The New Physics," or in similar works in the same pedagogic line.

The Latin should be studied from the philologic rather than the literary side, as so little is expected.

In regard to electives, the committee urged that all colleges allow a small margin of electives to begin in the second year and that each college make this work cover such branches as it is able to offer in the best quality. The value of even a small proportion, say five one-hundredths, of elective work in increasing the quality and spirit of all other work, can not be over-estimated when the resources of the school are such as to permit. Properly conducted the electives allow a choice of work adapted to the needs or inclinations of the students, while at the same time a larger number of medical teachers are given opportunity to devise and offer work some of which may be found of the greatest educational or professional value. Teachers may thus be discovered and methods of teaching thus be made known and the quality of teaching in the whole school greatly improved.

The following diagrams express the ideas of the committee on the proportion and disposition of the curriculum for the four years of the medical course. It will be noticed that chemistry and medical chemistry are crowded into the first year. This expresses the sense of the committee after very careful discussion. The committee holds that chemistry should very soon be required by the members of this Association for admission. The same may be said of biology or comparative anatomy. The high schools, academies and colleges now teach chemistry and biology by the laboratory method, and it will not long be necessary for medical colleges of the first class to teach either chemistry or biology.

1.—Diagram showing the distribution of the 600 "recitation periods" of the first year. The lateral divisions represent thirty weeks, the vertical divisions the twenty "recitation periods" each week. The first half of the materia medica should be pharmacognosy and the other half pharmacology.

ANATOMY.

The ground now covered in the course in anatomy is in accordance with the ideas of the committee. The separation of regional and surgical anatomy does not seem necessary or desirable.

This branch was relatively well taught in the older medical colleges, but improvements have not been made as fast as the importance of the subject demands. The study of vertebrate morphology is a prerequisite to the proper study of human anatomy. The time which anatomy receives in the diagram above is three recitation periods a week during the first semester of the first year and five recitations a week during the second semester. Each of these recitation periods would consume two and a half hours of the students' time. The first semester may be devoted to the study of osteology. Every student should have the bones

for his own use. The simpler parts of the skeleton should be studied first. The study of any bone should consist in a thorough study of every aspect of the organ with every pedagogical appliance. Drawings should be required in the various positions necessary to bring out all the parts. These drawings should at first be made from the object and later from memory. Only such features of the bone should be studied as the bones themselves present. Muscular attachments and the relation of other structures can not ethically or pedagogically be considered until the student sees the parts in position in the anatomic laboratory. In every possible way the teacher should maintain in the minds of the students the proper anatomic perspective and lead them to a vivid and indelible idea of the essential points. There ought to be an opportunity in every class exercise for students to propose questions. The recitation between the teacher and the students should be familiar and unrestrained.

The second semester of the first year should be spent in the dissecting room. This should be so fitted up as to be light, clean and commodious. The character of the dissections and laboratory study will depend not only on the motive and method of the teacher, but upon, and essentially upon, the proper preservation of the cadaver, the proper furniture of the laboratory and the proper equipment of the student with thoroughly good dissecting instruments, drawing books, note books and laboratory garments. A good workman must have good tools. In the dissecting room the muscles, nerves and vessels and their relation to the bones should be most carefully studied during the first year and all the dissections should be made so that these organs may be studied together. The bones should be at hand and the relations of parts studied and recorded by drawings. The muscles, for example, should be studied on the body, their separate offices demonstrated and their attachment recorded on the bones previously used. The blood and nerve supply should also be discovered and recorded on the drawings and sketches which each student should be required to make. Incidentally and in a general way the viscera should be carefully studied during the first year.

During the first half of the second year the careful study of the viscera should be begun. In this work it will be necessary if not desirable to use the organs of vertebrates for each member of the class in his laboratory examinations while the instructor will demonstrate from the human cadaver. All the important viscera should first be demonstrated in situ, then the organs of animals should be studied as detached specimens, and last of all each student should carefully dissect during the second semester the whole human body, making drawings and notes just as in the dissections of the first year.

During all this anatomic study the perspective of the subject should be carefully maintained by the teacher through demonstrations, recitations, quizzes and written exercises. The actual contact of the parts is of the greatest educational value and the use of dissecting gloves by students should never be countenanced. The necessity for a name should be felt by the student before he is required to learn a name. Anatomy should be a synonym for familiarity with the human body. Much attention should be devoted to the comparative study of the organs in the living human body. For this purpose students should be encouraged to use one another as subjects in the

class. In this course, little place is left for didactic lectures and much attention is devoted to doing with hand and eye. Manual dexterity is acquired by the student on the dead body.

It must not be forgotten that any method of teaching which secures in the student a rational curiosity and provides a way for him to satisfy it is a success, while a much better method so used as to paralyze the student's curiosity while it secures ever so good a command of the anatomic nomenclature is a failure.

Any text-book is good enough if it follows or accompanies the careful dissection of a well preserved cadaver in a well furnished laboratory.

A library of anatomic works should be in the dissecting room. A list of very desirable literature will be found in the August, 1895, number of the *Bulletin* of the American Academy of Medicine, pp. 273-276.

BIOLOGY, EMBRYOLOGY, AND HISTOLOGY.

Inasmuch as biology is an essential introduction to the subjects comprehended in the usual medical curriculum, and since but a small proportion of students present themselves with the knowledge of this subject upon entering the medical school, this committee believes that it becomes the duty of the medical school to supply instruction in elementary biology until the entrance requirements are raised sufficiently high to include this branch. The object of this biologic work should be to serve as a natural introduction to the study of the normal and diseased human body, and not to make zoologists or botanists of medical students. Most of this work can be presented by the object method in the laboratory, and as an outline of the work the following plan is submitted.

Course A. Elementary General Biology.—This course will serve to introduce the student to the use of the microscope, to elementary microscopic and laboratory methods, and to acquaint him with a broadened idea of the phenomena of life in animals and plants. As types for study in this we recommend amoeba, paramecium, vorticella, hydra, and earthworm on the zoologic side; and protococcus, yeast, bacteria, spirogyra, and molds on the botanic side. It is hardly to be expected that the teacher will be able to present all of these types in a given period and substitutes will doubtless be found necessary in certain cases.

In the laboratory exercises each student should be supplied with a microscope, and with simple equipment sufficient to enable him to independently prosecute all the technical work demanded. The laboratory exercises should be guided by simple directions such as are found in the "Practical exercises" of Huxley and Martin's *Practical Elementary Biology*. Free hand drawing from the object should be systematically demanded of every student in the class. Simultaneously with the laboratory work a reading or recitation course should be provided in which Parker's *Elementary Biology* will serve as an excellent text.

Course B. Elementary Vertebrate Anatomy.—Following Course A, in natural order, and serving as an invaluable introduction to descriptive and practical human anatomy, comes a laboratory study of several typical vertebrates. An elaborate study of comparative anatomy is impossible in the limits of a medical college course and it is expected that this course will prove mainly useful to the student in perfecting him in methods of anatomic laboratory study, while it incidentally familiarizes him with the anatomy of the animals chosen as types.

This study should be pursued almost entirely in the laboratory by the aid of a suitable laboratory manual; and a comparatively thorough study of one or two types should be encouraged instead of the cursory examination of a number. By means of suitable equipment the student should make such preparations as wet and dry skeletons, vascular injections, and preserved specimens. Numerous free-hand drawings made directly from the objects are to be required. As types for the work we recommend the frog, as studied after the directions in Huxley and Martin's *Practical Elementary Biology*, and one mammal, the rat, the rabbit, the cat or the dog.

On account of the convenience with which each student can handle his material, and on account of the greater delicacy of the dissections we consider the smaller mammals preferable, and for this purpose the dissection of the rat as prescribed by Martin and Moale in Vol. III of their *Handbook of Vertebrate Dissection* is especially recommended.

Course C. Embryology.—During the spring months when eggs can be easily obtained, and upon completion of courses A and B, the study of embryology should be begun. The foundation for a study of this subject is furnished by practical laboratory exercises.

The most convenient type for introductory study is the embryo chick which should be studied after the plan outlined in the "Practical Suggestions for studying the Development of the Chick" given in the Appendix of Foster and Balfour's *Elements of Embryology*. A series of whole embryos of characteristic stages of development are to be studied by the student, in the egg, both as fresh transparent objects, and as opaque objects. A series of typical sections are now to be prepared by the student from the material which he has obtained and preserved, and at this time the technique of killing, hardening, imbedding and sectioning for microscopic study can be acquired. Mammalian embryology can be introduced by several laboratory exercises upon the embryo pig or sheep. These embryos can usually be obtained in abundance from slaughter houses.

In connection with the laboratory work in this course we would prescribe reading or recitation exercises from some text-book, for example, Marshall's *Vertebrate Embryology*, Minot's *Human Embryology*, or Hertwig's *Text-book of Embryology*. Marshall's work will be found especially adapted to the laboratory course just presented, while the works of Minot or of Hertwig more properly serve as reference books for advanced students.

Course D. Histology.—In connection with Course A the student acquires a familiarity with the use of the microscope, and an elementary knowledge of the animal and vegetable cell both in unicellular and multicellular organisms. At this time also an acquaintance with simple microscopic technique is obtained.

Following that portion of Course B in which the frog is dissected the special study of elementary histology may be introduced. With the aid of such methods as teasing, maceration, dissociation, and possibly with some free-hand sectioning, the student should study the simple histologic tissues. A few of the more easily applied reagents should be employed by the student in his work upon the material which he obtains from his frog. Great weight should be laid upon the thorough mastery of the technique involved in this work, which is a step higher than that employed in Course A. A great deal can be done in the

study of the blood, epithelium, connective tissue, muscle and nerve, and even of some of the organs with a very simple laboratory equipment and easily acquired methods, and we believe it the duty of the laboratory teacher to impress this upon the student. The directions for histologic study in connection with the laboratory work upon the frog in Huxley and Martin's Practical Elementary Biology may with certain modifications, be taken as a guide for this portion of histology.

The study of histology proper may be suspended in favor of Course C in which the more elaborate technical methods of microscopic anatomy are introduced, along with the subject of histogenesis.

Upon the completion of this elementary course in the first year's work, the study of special histology as applied particularly to the tissues and organs of the human body should be pursued. This is the work in histology which we would prescribe for the second year's course, and with students already trained in ordinary laboratory methods, it will be possible to include more of the special and advanced methods of histologic research.

Here also each student should be provided with a full working outfit and it is expected that *all of the preparations demanded in the course are to be made by the student from the raw material which he obtains himself* or which is furnished to him by the teacher. These laboratory exercises can best be guided by type-written or mimeograph syllabi prepared by the teacher to cover each given lesson, and in these syllabi brief technical instructions should be supplied together with a few hints as to the observations to be made by the student, and the prosecution of technical details and the detailed study of the object should be left to the student. Drawings directly from the preparations should be demanded throughout the course and full descriptive notes should be prepared by the students.

As a supplement to the laboratory exercises in histology the students may be referred to one or more of the standard text-books upon histology, and in some special subjects it may be found advisable to introduce a few lectures.

This department ought also to possess a working histologic library. Text-books ought not to be used at all. The student should be referred to the library for the further study of the problems presented to him in his laboratory work.

THE COURSE IN PHYSIOLOGY.

The course in physiology should be continued through two years and should be in a general way coördinated with the course in comparative anatomy and general biology and histology. By coördination in this connection is meant the arrangement of the courses in such a way that the student shall learn first the more fundamental and general and then the more special. To teach the student the physiology of the liver one year and the gross and minute anatomy of that organ the next year must be recognized by all as an inversion the logical order. To teach the anatomy of an organ one year and its physiology the next year puts the teachers of both these branches at considerable disadvantage, and the chances are great that the student will have a less clear comprehension of the subject presented in this way than he would if the interval elapsing between the study of the more general branch and the more special branch be a short one.

Examples of coördination will be found in the arrangement of the following course in physiology:

Every course in physiology should be accompanied by laboratory exercises in which the student may familiarize himself with the technique of the subject and may demonstrate for himself the more fundamental facts of this science. The laboratory exercises should be coördinated with the recitations and demonstrations as far as it is possible to do so.

The first half of the first semester (eight weeks) should be spent in a study of the physiology of the cell as illustrated in unicellular plants and animals. While the student is studying the morphology of the protococcus, the yeast cell, the ameba and the paramecium in the biologic course he may profitably study the physiology of these organisms from such a text as, "The Cell" (Hertwig), and should repeat in the laboratory the experiments mentioned in Hertwig's book. "Allgemeine Physiologie" (Max Verworn, Jena, 1895) is a valuable help to the instructor who is conducting such a course.

The second half of the first semester should be spent on muscle-nerve physiology. Having already studied the reaction of ameba and paramecium to electricity, and having studied, in general histology, the structure of muscle fibers and cells, and nerve fibers and cells; further having made careful dissections of frogs and other vertebrate animals the student is in a position to comprehend and appreciate the reaction of muscle-tissue in response to various direct stimuli and to indirect stimuli applied to the nerve. The frog-heart and the "muscle-nerve preparation" are most used for such experiments. A convenient text to follow in the laboratory exercises is "Sterling's Practical Physiology."

Beginning with the second semester or second half of the first year the general subject of nutrition should be begun. Whether one introduces this field of physiology with the study of the circulatory system or of the digestive system is a matter of little consequence. The problems of the circulation being, for the most part, physical problems, would seem to justify the consideration of that subject first, followed by the respiratory system, which presents simple problems in mechanics, physics and chemistry. The student, having in the meantime made some progress in physiologic chemistry, is able to comprehend the general features of the chemie problems involved in digestion, and should now enter upon a systematic consideration of the nutrition: 1, food and foodstuffs; 2, preparation of foods; 3, mastication; 4, deglutition; 5, salivary digestion; 6, gastric digestion; 7, intestinal digestion; 8, absorption; 9, distribution; 10, assimilation or anabolism; 11, katabolism and animal heat, and 12, excretion. This course will probably consume the second semester of the first year and a part or all of the first semester of the second year. The remaining time allotted to physiology should be devoted to the physiology of the nervous system, the physiology of the special senses, and the physiology of reproduction. All of these courses should be accompanied by laboratory work. The laboratory manual already mentioned has exercises in all of the above subdivisions of the subject (except in reproduction).

After the student has completed the above required courses he should be given an opportunity to elect special courses in physiology during the second semester of the second year and during the third year. Profitable elective courses would be, for example: 1,

physiology of intrauterine life, following Preyer's "Physiologie des Embryos;" 2, special problems in the physiology of digestion, following Brunton in "Handbook for the Physiologic Laboratory;" 3, physical examination of the blood, using hematokrit, hemometer, corpuscle counter, micrometer, and staining methods; 4, experimental physiology of the central nervous system, following Cyon; 5, physiologic psychology, following Wundt or Ladd. The instructor may get much help from such works as: Cyon's "Methodik der Physiol. Experimente;" Gscheidlen's "Physiologische Methodik;" Foster and Langley's "Practical Physiology;" Schenck's "Physiologisches Practicum;" Brunton and Burdon-Sanderson's "Handbook of the Physiological Laboratory;" McGregor-Robertson's "Physiological Physics;" and Langendorf's "Physiologische Graphik."

THE ORGANIZATION AND EQUIPMENT OF THE DEPARTMENT OF PHYSIOLOGY.

Inasmuch as many of the colleges of the Association have not yet established physiologic laboratories, it is thought well to give a few general hints on the subject. The imposing equipments which one sees in the physiologic institutes of Europe, equipments which, in the aggregate, have cost many thousands of dollars, overawe one and make one hesitate to advise the undertaking of so great a task, so we are letting the years slip by without establishing physiologic laboratories. We must not forget that the equipment of European laboratories is a growth which has covered many decades; and further, that it is really advisable to allow a department to grow, collecting, in the course of a few years, an equipment which is perfectly adapted to the wants of the institution and to the special methods of the head of the department. The committee strongly advises the early establishment of physiologic laboratories, even if an institution can not appropriate for the purpose more than \$1,000 to start with. If an institution can devote to this department a well-lighted general laboratory room 36 ft. to 40 ft. square, with two or three small rooms for instrument room, workshop and library, and can appropriate \$1,000 to \$1,500 for the first equipment, then a laboratory fee of \$5 annually from each student who works in the department will, in the course of a decade, produce a sufficiently full equipment for all practical purposes.

At this point it may be well to give a hint as to the organization of the department, as this determines largely the character of the equipment and the number of duplications of each instrument.

The amount of personal supervision required by the student in practical physiology is so great that it is inexpedient to attempt to conduct large classes. A demonstrator and one assistant demonstrator can not properly supervise the work of more than thirty students at one time, even though each student be provided with a laboratory manual. In the organization and equipment here planned let it be understood that the laboratory class work in *sections* of thirty students each, and that each section be subdivided into ten *divisions* of three students each. Now, experience in many laboratories has shown that a student will accomplish practically as much in one laboratory period of three hours as in two laboratory periods of two hours each. The three-hour laboratory period promotes economy both for the student and for the department. Following this arrangement, two instructors would be able to

supervise the work of 180 students, meeting one section of thirty students each day. With this allotment of time each student would have three hours of laboratory work each week during the year, which would enable him to demonstrate for himself all of the fundamental principles of physiology. In the question of the choice between, 1, the condensation of 180 hours of laboratory work in physiology into a period of sixty days with three hours per day, and 2, the distribution of the same number of hours over sixty weeks (two years) with three hours per week, and its coordination with the theoretic work in physiology and with the courses in gross anatomy and histology we would, without a moment's hesitation, decide in favor of the latter plan.

If this general plan of organization be adopted, and if the department wishes to provide for sections of thirty students, working in ten divisions of three students each, then the apparatus should be duplicated in tens. The following list of apparatus is suggested as a practical one with which to make a beginning:

EQUIPMENT FOR GENERAL LABORATORY WORK.

10 strong tables, 8 feet by 2½ feet, at \$7.50	\$75.00
10 kymographs, at \$30.	300.00
20 Daniell's cells, half gallon size, at \$3.	60.00
4 pounds of copper wire, No. 16, double cotton cover, at 60 cts.	2.40
½ pound copper wire, No. 26, double silk cover, at \$2.50	1.25
10 bichromate cells, medium size, at \$3.	30.00
10 simple compasses (for detectors) at 30 cts.	3.00
10 mercurial keys, at 50 cts.	5.00
10 contact keys, at 60 cts.	6.00
10 DuBois keys, at \$1.50.	15.00
40 Oxford rheochords, at \$2.50	25.00
10 Du Bois-Reymond, induction machines, at \$15.	150.00
10 Pohl's commutators with crossbars, at \$2.	20.00
10 pairs of muscle forceps, at 75 cts.	7.50
10 pairs of tambours, at \$4.	40.00
20 heavy-base stands, with fixtures, at \$2.	40.00
10 Bunsen burners, at 25 cts.	2.50
10 bell jars, at 80 cts.	8.00
10 double-valve rubber bulbs, large size, at 75 cts.	7.50
5 hemometers (Fleischel's), at \$15.	75.00
5 sphygmographs (Dudgeon's) at \$20.	100.00
5 blood corpuscle counters (Zeiss) at \$15.	75.00
General surgical appliances, forceps, shears, etc.	50.00
Assorted sizes of glass tubing	5.00
Assorted sizes of soft rubber tubing	5.00
Rubber stoppers, assorted sizes, perforated.	2.00
Corks and cork borers, sheet cork.	2.00
Files, "knife-blade" for cutting glass tubing.	2.00
Glassware, gas generators (2), graduated cylinders, pipettes, flasks, bottles, beakers, etc.	50.00
Granite iron troughs and basins, assorted sizes	10.00

\$1,174.15

NOTE.—About one-third of this outlay can be saved by having five divisions of the section work on one problem while the other five divisions work on a related problem which involves other instruments. That would reduce the absolutely necessary equipment to \$500.

INSTRUMENTS FOR SPECIAL USE AND DEMONSTRATIONS.

1 galvanometer	\$50.00
1 metronome	4.00
1 hematokrit	5.00
1 plethysmograph.	2.50
1 pair quantitative balances	30.00
1 pair dog scales	15.00
2 pairs medium scales for students' use.	10.00
2 mercurial manometers for blood pressure	10.00
2 Ludwig rheometers.	10.00
1 moist chamber.	20.00
1 capillary electrometer (Kühne's)	5.00
1 Du Bois-Reymond rheochord	25.00
1 contact clock.	40.00
2 chronographs.	20.00

\$266.00

This list might easily be extended to amount to several thousand dollars, but it is intended here to include only those instruments which seem necessary to start with.

THE WORK SHOP.

Demonstrators and students can easily construct, in a shop, many pieces of simple apparatus, which if purchased of some instrument house, would amount to many times the cost of the material and would deprive students of some very valuable experience. Frog, rat, rabbit and dog holders may be made, the tambour frames may be furnished with membranes and mounted as receiving or transmitting tambours, cardio-

graphs, or stethographs. All writing levers, electrodes, etc., should be made by the students. A room with bench and vice and \$25 for carpenter's and machinist's tools would be an ample start.

A FEW NECESSARY CHEMICALS.

20 pounds CuSO ₄	\$1.30
10 pounds H ₂ SO ₄70
5 pounds mercury.....	3.30
5 pounds bichromate of potassium.....	.75
5 pounds kaolin (for electrodes, etc.).....	.25
2 drams of curare.....	2.50
5 pounds gum damar.....	1.25
20 pounds benzol.....	4.00
[2 per cent. sol. of damar in benzol makes the best fluid for fixing tracings made on smoked paper.]	
10 pounds chloroform (imported duty free).....	5.00
30 pounds sulphuric ether (imported duty free).....	9.00
20 pounds surgical cotton at 25 cts.....	5.00
2 pounds sealing wax in sticks.....	1.00
1 pound mercuric chloride.....	.80
2 pounds carbolic acid.....	.70
5 gals. abs. alcohol.....	
2 pounds sodium hydrate.....	
2 pounds magnesium sulphate.....	
2 pounds sodium chlorid (pure).....	
10 pounds glycerin.....	
1 pound hydrochloric acid.....	
1 pound nitric acid.....	
1 pound ammonium hydrate.....	

About \$50.00

A WORKING LIBRARY OF PHYSIOLOGY.

Beside the laboratory manuals enumerated under the "Course in Physiology," we mention a few journals and general works that should be in every laboratory of physiology: Hermann's "Handbuch der Physiologie"; *Journal of Physiology*, ed., Michael Foster, Cambridge, England; Pflüger's *Archiv f. d. gesammte Physiologie*, Bonn, Germany; *Archiv für Anatomie und Physiologie*, [physiol. part] ed., Du Bois Reymond, Berlin, pub., Veit & Co., Leipzig; *Centralblatt für Physiologie*, pub., Franz Deuticke, Leipzig; *Journal of Experimental Medicine* [physiological part edited by Bowditch, Chittenden and Howell], D. Appleton & Co.; "Animal Physiology," Mills, D. Appleton & Co., 1889; "Text-book of Physiology," Michael Foster, Macmillan, 1888-93; "Human Physiology," Landois and Sterling, Blackiston, Philadelphia, last edition; "Refraction and Accommodation of the Eye," Landolt, Lippincott, Philadelphia, 1886; "The Frog," Marshall, London, 1894; "Anatomy of the Frog," Ecker, Oxford, 1889; "The Cat," Mivart, Scribner, 1881; "Dissection of the Dog," Howell, Holt & Co., 1888; "Anatomie des Hundes," Ellenberger & Baum, Berlin, 1891; "Dictionary of Medicine (4to), Gould, Blackiston, Philadelphia, 1895.

Beside these there should be recent representative manuals of histology, general biology, embryology, chemistry and physics.

PHYSIOLOGIC CHEMISTRY.

It has been taken for granted that the chemic problems of physiology will be assigned to the department of chemistry. The equipment of that department makes such a division of the subject highly advantageous. For years urine analysis has been taught, usually in the second year of the course in the department of chemistry. Many of the stronger institutions have long since expanded the second year course in chemistry into a very creditable course of physiologic chemistry, beginning with an investigation of food-stuffs, following this with qualitative and quantitative work on the chemistry of digestion, and devoting the last semester of the second year to the analysis of urine. The best laboratory manuals on this subject are: Sterling's "Practical Physiology" (first part); Long's "Laboratory Manual of Chemical Physiology," Colegrove & Co., Chicago, 1895; Halliburton's "Essentials of Chemical Physiology,"

Longmanns, Green & Co., 1893. The physiologic library should contain also: "Text-book of Chemical Physiology and Pathology," Halliburton, Longmanns, Green & Co. 1891; "Physiologische Chemie," Bunge, Vogel, Leipzig, 1894; "Lehrbuch d. physiologisch. Chemie," Neumeister, Gustav Fischer, Jena, 1893; "Physiological Chemistry," Hammarsten, Wiley & Sons, New York, 1893; "Physiological Chemistry of the Animal Body, Gamger, Macmillan, 1893; "Chemical Physiology and Pathology," Hoppe-Seyler.

(To be continued.)

REPORT OF A CASE OF GALLSTONES.

BY T. R. MOSS, M.D.

DYERSBURG, TENN.

My reason for presenting this report is the obscurity which enveloped the diagnosis as well as the long train of unpleasant symptoms in its history. I do not arrogate to myself the ability to teach this intelligent body, but hope to learn something from the discussion which will prove beneficial. Through the kindness of my friend, Dr. N. S. W., on May 24, 1895, I was called with him to see Mrs. J. M. B., who had been ill about two weeks. She was brought up to know nothing of the blightings of poverty, but had every want gratified, and moved in the topmost social circles. She weighed 230 pounds, and was 41 years of age. She lived a sedentary life and as a result was troubled with constipation. Aside from this her health had always been perfect, except that about eighteen months previous she had an attack lasting ten or twelve days with symptoms of biliary obstruction. She enjoyed to a high degree the good things with which she provided her table at all times and on the date the present attack began partook quite heartily of the midday meal, eating among other things freely of cold slaw. Two hours after this she was seized with an intense pain in the epigastro-hypochondriac region extending back under the right scapula, from which in some degree she was not free for several months. The pain did not continue severe all the time, but there was a constant burning as if a coal of fire had gotten into the stomach, which was very much intensified on taking food or drink of any description. This burning and pain was accompanied with vomiting, severe and persistent, made worse by irritation from ingesta, but coming on at intervals when nothing at all was swallowed. It consisted mainly of acid glairy mucus in which at long intervals were intermingled minute specks of blood. Dr. W. stated that prior to my first visit no elevation of temperature had been observed and on this occasion the mercury registered only 99½ degrees Fahrenheit. Examination revealed a very tender and painful spot on pressure just below and to the right of the ensiform cartilage. No tumor could be detected. The pain, tenderness and persistent vomiting suggested the possibility of gastritis, which Dr. W. had under consideration. Jaundice was present, but not nearly so marked as it became later on. The temperature began to range higher, the pain and vomiting persisted, no kind of treatment seeming to give even temporary relief. In the course of a few days Dr. S. of Memphis was called and after a very careful examination gave as a diagnosis, hepatitis. By this time the jaundice was more marked and deep palpation indicated engorgement and sensitiveness to pressure in the liver. While Dr. S. favored the idea of hepatitis which might become sup-

purative, yet he related an instance where a patient without symptoms to particularly indicate such result developed malignant disease. The symptoms continued without abatement, rigors occurring but no sweating except that which came as the result of antipyretics. A few days after Dr. S.'s visit he was communicated with by telephone, when he advised aspirating the liver for pus. His presence was desired but he could not come. The persistency of the pain in the same locality, the obstinate vomiting, the rapidly increasing jaundice of the conjunctivæ, skin and urine, clearly indicating the presence of bile in abundance, the pyrexia, rigors and absence of bile in feces, connected with the sudden onset suggested to Dr. W. and myself the possibility of biliary obstruction. Therefore on the morning of June 13, we administered six ounces of olive oil and in the afternoon of the 14th there were several alvine evacuations heavily charged with bile. We regret the discharges were thrown away before a careful search was made for calculi. The diagnosis still being unsettled Dr. Rogers of Memphis was telephoned for, but was sick. Dr. A. B. Holder, his worthy associate, came up on the morning of the 15th and after a most thorough and critical examination advised an exploratory operation for the purpose of ascertaining the cause of trouble. Accordingly preparations were made for operating instantaneously. An incision was made over the region of the gall bladder and that organ partially exposed. On account of the superabundance of adipose tissue it seemed almost like going down into a well in order to reach the point desired, and when the gall bladder was found, it was adherent to the surrounding parts and could not be brought well up into the wound. It was contracted and of semi-solid consistency. This semi-solidity in the doctor's opinion amounted to a "stony hardness." The sensation as given to my touch, however, was that as stated above.

The contracted condition of the gall bladder, the "stony hardness," its fixedness and the apparent absence within its cavity or in the ducts of calculi seemed to preclude the advisability of further operative interference. After palpation and inspection, and as a matter of precaution introducing the aspirator with negative result, the liver was thought to be normal, and therefore hepatic abscess eliminated. Considering the trouble irremediable and most probably malignant, Dr. Holder so announced and proceeded to close the opening. The patient bore the operation splendidly and re-acted well. There was at once a decided amelioration in the symptoms, the temperature ranging below 100 F., the pain not so severe, the vomiting more infrequent, the dejecta continuing to show the presence of bile, the urine rapidly losing its saffron hue, and the skin and conjunctivæ gradually assuming their normal appearance. At the time it was difficult to divine whether the change was due to the olive oil on the 13th followed by bilious discharges on the 14th, or the operation on the 15th with the manipulations necessary to the same. Competent observers say that aspiration of the liver, though no pus be found, is often followed by improvement, hence this might be the reason. On the other hand occasionally calculi are entirely liquefied and not discovered with the most careful search. The latter seemed the most plausible. After several back-sets attended with high fever in which quinin was freely and effectively used, she finally became able to sit up a short while each day. This was done with a great deal of distress as

the nausea was very much aggravated and a "stuffed feeling" and sense of heavy weight was much more pronounced on assuming the erect position. The desire for food became stronger so that on August 28 she ventured to indulge to a very limited extent at the midday meal. During the afternoon the pain returned, but radiated in every direction so that it was mistaken for ordinary colic and a simple remedy administered. It failed to give relief and as the pain grew more intense, an opiate by hypodermatic injection was resorted to. On the morning of the 29th a rigor occurred, and the temperature ran to 102. Later in the day another rigor, and the temperature rose to nearly 105 F. The urine became loaded with bile, the conjunctivæ and skin rapidly assumed a deep yellow, the lips and finger tips were cyanotic, the facial expression pinched, and the pulse 130. Dr. W. was sick and I was left alone. I gave antipyretics with baths and immediately began the rectal administration of quinin 100 grains in the twenty-four hours. This was kept up several days. In this way the temperature could be somewhat controlled. On lessening the amount of quinin the temperature would rapidly increase and upon its resumption would again subside. Hence this heroic dosing was justified. Saturday morning, August 30, I gave six ounces of olive oil by stomach, which was retained and in the afternoon of the 31st she passed a gallstone about the color and size of a hazel nut. This was like an oasis in the desert, and temporarily there was a change for the better. Everybody was inspired with hope, but the irritable stomach remained, great mouthfuls of mucus and saliva would collect, the vomiting persisted and it seemed beyond the ingenuity of man to suggest a form of nourishment which could be retained. To this was added an aching in the limbs, most prominent in the left arm and leg, with a burning in the bottom of the feet. These symptoms, with extreme hot weather, conspired to make our patient devoutly wish for death. This continued until hope was again nearly extinguished, when to our dismay the pain grew more intense, the stomach again became if possible more irritable, the vomiting of glairy mucus more frequent, and the skin, urine and conjunctivæ indicated the resaturation of the blood with bile. The bowels being constipated, I administered a C.C. pill improved, and the next afternoon was rewarded by finding a second gallstone, larger than the first. During the interval between the passage of these stones, a considerable quantity of inspissated bile was passed. From the passage of the last stone the improvement was slow but continuous until the feeling of fullness, pain and discomfort had entirely disappeared, and she could eat anything she desired with impunity. The skin, urine and eyes cleared—and flesh began rapidly to accumulate. The suffering in the limbs did not entirely cease, but with this exception perfect health seemed about restored, when March 18, 1896, she was again seized with pain and burning exactly as before with a temperature of 103, but no vomiting. Jaundice made its appearance within twelve or eighteen hours and every symptom pointed to a return of the original malady. Eight ounces of olive oil were given within a few hours and was followed by a whitish, pasty stool the next day. Several ineffectual efforts were made as manifested by pain for the stone to be forced through the duct. Full doses of calomel followed by salines, phosphate of soda, and C.C. pills improved, each were tried, but the

feces still showed an absence of bile. Evidently the cessation of each paroxysm was caused by the stone slipping back into the gall bladder as the burning and most of the tenderness disappeared with the pain. The attacks came from two to four hours after the midday meal, when more food was taken and hence a greater demand for bile to aid in its digestion. The tertian type of intermittency, which the paroxysms assumed, excited the suspicion that in some way a malarial element was a factor in the causation. Therefore I saturated the system with quinin and on the night of the 28th gave two C.C. pills improved. On the morning of the 29th a third stone was found, similar in size and color to the others.

Because of its effect on the catarrhal swelling as well as a relaxation of the duct walls, I suspect the quinin was an important factor in aiding the expulsion of the stone. I may be subject to criticism here as well as at other points in my paper. At the time of this writing the patient is again rapidly convalescing.

You can readily see the diagnosis in this case was not easily settled, and because of this the interest became very intense to those directly concerned. The history of perfect health with the exception mentioned, the free indulgence in cold slaw, and the sudden onset of pain a short while after, the vomiting, the burning so persistent and severe that an ice bag was kept over the epigastrium constantly for three weeks, the foul breath, the rapid, small pulse heretofore not mentioned, pointed with so much positiveness to gastritis that it was perfectly natural that this should be considered. There can be no doubt about the presence of an acute gastro-duodenal catarrh resulting from irritation to surrounding parts of the impacted gallstone. This catarrh came near costing our patient her life through its interference with the nutritive process. Hepatic abscess frequently forms in such an insidious manner as to deceive if possible the very elect. I remember a case occurring in Bellevue Hospital under the service of E. G. Janeway, which had been mistaken for a remittent form of malarial fever, and I call to memory just now a case in the practice of a country physician where an old man of 70 developed the history of abscess of the liver, but a diagnosis to that effect was not made. Finally rupture into the lungs took place, and death from apnea was the result. Again, in my own practice, as a sequel to an attack of dysentery an old man of 60 presented the symptoms of suppurative hepatitis with the exception that instead of bulging there seemed to be a retraction of the right hypochondrium. The aspirator was not introduced, and the patient died without rupture or a verification of the diagnosis. In the case under consideration the symptoms suggestive of inflammation and later suppuration in the liver were: 1, climate; 2, the free indulgence in rich, highly seasoned food; 3, sedentary life with constipation; 4, gastro-duodenal catarrh; 5, jaundice; 6, pain and tenderness; 7, fever and rigors. On the other hand, suppurative inflammation of the liver is rare in women, and the pyrexia and rigors are usually attended with profuse sweating. Jaundice, to a marked extent, is generally absent, and when present is *per se* not a valuable diagnostic symptom, depending as it does on a catarrhal swelling of the bile ducts or pressure on these ducts from accumulation of pus. Pain is not so acute or suddenly developed, as a rule, unless associated with a local peritonitis. The question of malignancy was the one which gave us most concern.

Bartholow says: "When at or after middle life, in a patient with a history of former attacks due to gallstones, there begins a fixed pain in the right hypochondrium and subsequently retention jaundice, the existence of a malignant growth in connection with the cicatricial tissue and ancient organized exudation should be suspected, and this suspicion will be confirmed if subsequently a tumor can be felt." Again, "and especially are organized exudations the favorite seats of cancer, new formations, those for example about the gall bladder and cystic duct resulting from repeated attacks of passage of calculi." The persistency of the pain, the history of a former attack, the contracted and adherent gall bladder, and the vomiting, age considered, presented an array of symptoms suggestive of malignant trouble, yet the slow development, the fawn or bronze color of the skin, prior digestive disturbances, a peculiar cachexia and the existence of a tumor were conspicuous by their absence. Having taken a running survey of the premises, what are the indications pointing to gallstones as the source of trouble? 1, climate; 2, gallstones are more frequent after 40 years of age; 3, women are especially liable to them, the ratio as compared to men, according to Thudicum, being three to two, and according to Cyr four to one; 4, sedentary life and indulgence in the pleasures of the table; 5, the history of a similar attack, though of shorter duration, preceded and followed by uninterrupted good health; 6, the abrupt onset with the characteristic pain, followed shortly by jaundice indicating biliary obstruction which had not the time to form outside and occlude by pressure, but must be inside the duct or ducts, preventing the transit of bile; 7, the passage of typical gallstones, though this may take place in connection with malignant disease; 8, the gradual return to health as indicated by cessation of all pain, vomiting or inconvenience of any description whatsoever in the regions of the stomach, gall bladder or liver, a clear, healthy skin and re-accumulation of flesh to nearly two hundred pounds.

I have reached the following conclusions:

1. The diagnosis of simple gallstones, especially when impacted in the common duct as these were is not always an easy matter.

2. Two of these stones were lodged in Vater's fossa for a period of two months in the case of the first and three months in that of the second.

3. The slight diminution in the severity of the symptoms after the passage of the first stone was due to the lessened distension in the duct by the one remaining.

4. Sweet oil probably has some virtue in biliary obstruction as evidenced by the copious discharges of bile following its first administration and the expulsion of a stone after the second; but the fact that it was given several times without result (which I did not mention in order to avoid details) and two of the three stones accompanying the purgative action of C.C. pills imp. lessens to some extent the confidence in oil, giving rise to the thought that any active cathartic might do as well and that the passage of the stones into the intestines was due to the combined influence of quinin and morphin.

This case is one fraught with considerable interest to me. I would be glad to have an expression from those of experience in this assembly. It would be interesting to know what per cent. of obstructed bile ducts take on malignant growth.

It is through the friendship existing between Dr. Walker and myself that I report this case. His absence during a part of the first attack, as well as all of the last, was due to ill health.

SOCIETY PROCEEDINGS

Tri-State Medical Society.

Abstract of the Proceedings of the Fourth Annual Meeting, held in Chicago, April 7, 8 and 9, 1896.

The Society met at the Great Northern Hotel, and was called to order by the President, Dr. R. H. BARCOCK, of Chicago.

After the reading of the minutes of the last meeting by the Secretary, the report of the Treasurer, and reports of standing committees, the President delivered his Address. He selected for his subject

ANTITOXIN OR SERUM THERAPY.

He said the crowning achievement in this line of work had come through the chemistry of bacteriology. Nuttall conclusively demonstrated in 1888 the power possessed by the blood serum of combatting the poisonous products of bacterial growth, but to Behring and Kitasato in 1891 belonged the credit of having found a practical means of utilizing antitoxins in the treatment of disease. To those who deery the antitoxin treatment of diphtheria as dangerous and its advantages as not yet proven, Dr. Babcock commended the criticism by Welch in the *Johns Hopkins Bulletin* of October, 1895. His (Welch's) analysis of cases treated and published up to that time, in the opinion of Dr. Babcock, sets at rest all doubt concerning the great reduction in mortality accomplished by this treatment, and renders the physician culpable who refuses this remedy to his patients. Sufficient experiments on lower animals and trials on human beings had already been recorded to warrant the belief that we shall soon possess an effectual weapon against tetanus. Attempts had been made to treat typhoid fever patients with serum obtained from dogs rendered immune and from convalescents, but as yet observations were too few to warrant a more extended discussion of serum therapy in this class of cases. Dr. Babcock then traced the efforts that had been made to combat tuberculosis by means of serum therapy, telling of the first discovery that certain animals possess comparative immunity from the disease. Detailing several experiments, he said a more intelligent use of tuberculin seemed to show that the early failures were due not solely to the inefficiency of the remedy, but to its injudicious employment in too large doses. He next passed on to a personal trial of the remedy, citing the case of a young woman of 21 years, whose sister had died of pulmonary tuberculosis, and in whom well-marked signs of inactive disease existed in the right apex. The administration of antiphtisin for two months was followed by a gratifying disappearance of the malaise, nervousness and occasional light cough. He also treated a male aged 34 with satisfactory results. Dr. von Ruck had furnished Dr. Babcock with advance sheets of a report, published in this *JOURNAL*, April 11, 1896, of 182 cases of consumption in all stages treated with tuberculin and antiphtisin, in which recovery was obtained in 32 per cent. of the cases, arrest or marked improvement in 30 per cent., and some improvement in 16 per cent. In closing, he said that whatever had been thus far accomplished, the field was broad and would repay painstaking investigation along the line of the antitoxin treatment of tuberculosis.

SPECIAL EDUCATION AS A MEANS OF TREATMENT IN CHRONIC NEURASTHENIA.

This paper was read by Dr. J. F. PERCY, of Galesburg, Ill. Neurasthenia was considered the result of an imperfectly used and therefore improperly developed nerve organization. His treatment is to take patients out of and away from themselves, so to speak, and he knows no better way of doing this than to educate them as to the real facts back of their morbid tendencies. In this city there is an ably conducted kindergarten normal school, and when he has a neurasthenic woman he sends her, if possible, to this school to take the normal course there. The result has been that every case so treated has recovered. Moreover, he believes he has lifted the life of his patient to a higher level of thought and action. In one case the right ovary was buried in a mass of exudate beneath the uterus. Electricity, and especially pelvic massage, were practiced for over a year with but little appreciable result. He stopped all treatment and insisted that the woman take a kindergarten normal

course, which she did, and the result is that to-day she is well, so far as any morbid mental phenomena are concerned. The course of instruction should be carried out by competent teachers, setting at rest the nervous system, so far as receiving and being influenced by morbid impressions. The teaching should be suggestive rather than direct. It is necessary to classify the patients and instruct them by degrees. This plan, which he had merely hinted at, would do more for cases of neurasthenia than anything else of which he was cognizant.

Dr. A. H. CORDIER, of Kansas City, Mo., followed with a paper entitled

CANCER OF THE UTERUS COMPLICATED BY PREGNANCY; INDICATIONS FOR OPERATION.

The author reported a successful case of vaginal hysterectomy in a woman 32 years of age, the uterus being three months pregnant. Of 27 cases tabulated by Dr. Vander Veer, of Albany, 5 died during labor undelivered, 9 died during the puerperal period, 3 results not mentioned, and 10 recovered, the mortality to mothers being 60 per cent. Another author reports 34 cases of cancer of the uterus, complicated by pregnancy, with a mortality of 52 per cent.

Dr. Cordier drew the following deductions:

1. Cancer of the cervix uteri, if left without surgical interference, always kills.
2. The disease, in most instances, is primarily a local process.
3. Early hysterectomy will cure quite a percentage of these cases.
4. The microscope, while a great diagnostic aid, is not infallible in its findings.
5. The experienced surgeon is warranted in resorting to hysterectomy, even in doubtful cases.
6. All malignant pregnant uteri should be removed when seen, before the disease has advanced beyond the period of a probable cure.

Dr. RYAN, of Galesburg, cited an uncomplicated case of cancer of the cervix which occurred in the hands of another practitioner, and in which the cervix was amputated, the patient being four months advanced in pregnancy. Following the operation she went on to full term and the child was delivered without difficulty.

Dr. L. H. DUNNING, of Indianapolis, said that if he should find hardening of the cervix and the development of a neoplasm with the presence of discharges, sanguineous or offensive in character, even though the microscope failed to reveal positively the existence of malignant disease, he should be inclined to pursue the course recommended by the essayist. Relative to the advisability of removing the cervix alone, it might be done if the surgeon is certain that the epitheliomatous variety exists; yet the woman's life was in peril after the neoplasm is removed because of the scar tissue which remains. A case corroborative of this point was cited.

Dr. RUFUS B. HALL, of Cincinnati, thought the whole matter hinged upon the diagnosis. When the diagnosis was accurately made, it is perfectly clear what should be done. He favors total extirpation, believing that high amputation should only be done in exceptional cases.

Dr. D. C. BROCKMAN, of Ottumwa, Iowa, emphasized the importance of early diagnosis. He believes the fault in these cases lies largely with the general practitioner, who does not understand the importance of irregular hemorrhages occurring in women approaching the menopause, and who prescribe a placebo at a time when a radical operation is needed.

Dr. BYRON ROBINSON, of Chicago, concurred with the essayist that the microscope alone was insufficient in many cases to enable the surgeon to make an accurate diagnosis of malignant disease of the cervix, and that more stress should be laid upon the clinical history of the case.

DIFFUSE PELVIC INFLAMMATION.

This was the title of a paper contributed by Dr. L. H. DUNNING, of Indianapolis. Five cases were reported in which vaginal hysterectomy was resorted to for inflammatory disease of the uterus and appendages, after which the author summarized as follows:

1. In all of his cases, except one, the uterus on removal was found to be markedly diseased beyond a glandular endometritis.
2. In the two cases in which the uterus and appendages were fixed the operation was most difficult. The uterus in either case was little diseased. The chief pathologic lesions were double pyosalpinx and pelvic peritonitis. The operation would have been easy and the results quite as good by the abdominal method.
3. In these cases the appendages were much more inaccessible and less open to ocular inspection than in the abdominal operation.

4. In his experience in clamp cases the pain after vaginal hysterectomy is greater the first two days than after celiotomy.

5. The systemic disturbances, as evidenced by the temperature after vaginal hysterectomy is lower the first three or four days, but is higher after six to ten days, when the sloughs begin to give way.

6. In two cases in which ligatures were employed instead of clamps, abscesses in the stumps of the broad ligament followed, retarding the recovery of the patients. Many cases of abdominal section were done in the hospital during the same time, and in none of them did abscess appear.

7. In one case of the five, prolapsus of the vaginal walls appeared a few weeks after the patient began to walk around. This was a ligature case. Such a prolapsus he had never witnessed in a forceps case.

8. In three of the cases the same pain and nervousness followed the recovery as sometimes witnessed in cases of abdominal section. In two of the cases the pain and nervousness passed off after several weeks, as it usually does after abdominal section.

DR. RUFUS B. HALL said that women should be educated up to the point of avoiding septic infection, suppurating tubes and ovaries. The young men likewise should be educated to avoid gonorrhea in order to prevent infecting their wives in future years. This being accomplished, gynecologists would have less pus tubes and diseased ovaries to remove.

DR. T. J. WATKINS, of Chicago, believes there are cases which should be operated on by vaginal incision and drainage, while there were others in which the abdominal route was preferable. All large pus collections in the pelvis that could be opened and efficiently drained without entering the peritoneal cavity should be treated by incision and drainage through the vagina or above Poupart's ligament. Vaginal hysterectomy should be the operation of election in old backward displacements where the uterine appendages are destroyed by suppurative disease.

DYSURIA IN WOMEN.

DR. O. B. WILL, of Peoria, read a paper on this subject. Acting upon the assumption of the zymotic origin of the trouble, his first thought was to neutralize the fermentative action taking place in the lower sections of the digestive tract. For this purpose he had used with great success charcoal and sulpho-carbolate of soda, the former administered in tablet form, 5 grains or more at a time and frequently repeated; the latter in half drachm or more doses, three times a day, before the taking of the respective meals. As to the local treatment, years ago he used with success in these cases of irritable bladder and urethra a strong solution of nitrate of silver, injected into the organ, the resulting pain being held in abeyance by the use of large doses of morphia. Coupled with this forcible dilatation of the urethra for fissure came into vogue, and in some cases seemed to answer a good purpose. Wherever a state of tissue tension exists and free drainage is desirable, the stretching process is an admirable therapeutic adjunct and is a preliminary measure to the treatment to which the author now resorts. The patient is placed in the elevated dorsal position advised by Kelly in exploring the bladder and catheterizing the ureters. After quickly mopping out the residual urine, if there is a hyperemic or analogous condition of the trigonal region, he applies at once on the most dependent portion of that region, from a long pointed syringe, a few drops of a 10 or 15 per cent. solution of potassa permanganate. Preliminary to this, however, he uses a 10 per cent. solution of cocain with which to dilate the urethra, a few drops of which introduced into the bladder serves to obtund in some measure the sensibility of its mucous lining. In cases where the whole tract from that point to the meatus is in an evident state of irritation, either with marked hyperemia or in an eruptive condition, he quickly swabs the pendent area of the bladder with cotton on a screw applicator, soaked in the permanganate solution, and, making sure that there is no sharp point to the applicator exposed, with it draws the charged cotton out through the distended urethra, following in the tract of the withdrawn speculum. After the application of the permanganate to the urethra it is generally advisable to introduce within a few minutes a large sized bougie, heavily coated with lanolin, especially on the end, so that the lubricant may adhere more abundantly and extensively to the urethral wall. Even in those cases of dysuria associated with eczematous and urticaria-like eruptions in urethra and bladder, he had recently found this treatment to be most effective.

DR. E. O. SISSON, of Keokuk, Iowa, read a paper entitled

ULCERATIVE INFLAMMATION OF THE CORNEA.

The author first dwelt upon the etiology, and then passed on to the subdivision of keratitis suppurativa. Symptomatology

and complications were next considered. With regard to the treatment of corneal ulcers, the author reiterated the methods laid down in the several text-books.

DR. ALEX. HUGH FERGUSON, of Chicago, read an interesting paper on

PYLORECTOMY IN AMERICA.

He said the literature up to date only shows thirteen resections of the pylorus in this country, and of this number eight died, and five recovered. The first successful pylorectomy performed in this country was by Dr. Wm. T. Bull, of New York. The proportion of deaths immediately following the operation places shock as the most prominent cause. In none of the cases reported is the nature of the shock stated, that is, whether it was manifested by marked cardiac inhibition nervous depression, or excitement. The author then reported a case upon which he had successfully operated. He is strongly in favor of encouraging pylorectomy for carcinoma of the pylorus, for the following reasons:

1. Medical treatment offers a mortality of 100 per cent. within twelve or eighteen months.

2. Pylorectomy promises a possible cure. In 19 per cent. of over nine hundred cases dying with cancer of the pylorus, no adhesions whatever were found after death; starvation took place before the carcinoma had reached the peritoneum. There would be good prospects of curing most of these. Recovery from the operation occurs in about 50 per cent. Death occurs in 43.7 per cent. while the disease is still local, *i.e.* no secondary deposits, or extension beyond the pylorus. Surely some of these could be saved. A still less mortality takes place with early operation. By timely interference many cases could be saved that now go on to secondary infection, and are doomed. To secure the best possible results shock must be anticipated and measures taken to prevent it. In addition to the hypodermic injection of strychnia before the operation is commenced, the author is convinced from a large experience in major work that when the patient is placed on a hot water bed during the operation that shock, which otherwise would have been pronounced, is in many cases altogether prevented. He feels certain that this precaution was a material contributing element to the success of his pylorectomy case. After opening the abdomen, he recommends the performance of pylorectomy thus:

1. Liberate the duodenum from the pylorus, unite its distal cut end to the posterior surface of the stomach with Murphy's button and invert the proximal cut end toward the pylorus and close with sutures. The great advantage of completing the gastroduodenostomy first, is that the operation can be safely stopped at this stage should the patient show signs of weakening, the abdomen at once closed, and the removal of the pylorus left for a second operation.

2. Separate the stomach from the pylorus and close it rapidly with sutures. Should the patient now present alarming symptoms, the surgeon should again cease operating and leave the pylorus *in situ* in the meantime. It would, of course, be necessary to fasten it in the abdominal wound and drain it externally, which, however, would only facilitate its extirpation at another time.

3. Remove the cancerous pylorus. Spend no time in trying to use interlocking ligatures, but apply forcep after forcep and cut the mass away. This done, the application of ligatures can be executed more expeditiously.

LOCAL TREATMENT OF THE EYE

was the title of a paper read by DR. DUDLEY S. REYNOLDS, of Louisville, in which he said that the local treatment of the eye was as much in need of reform and readjustment as in any other department of surgery, for there had been little change in prevailing customs for nearly a hundred years. It seems to him that it is rational for practitioners to get out of the nitrate of silver path of destruction and quit furnishing the aid of cauterization to the less destructive processes of a surface inflammation. Boric acid will protect abraded surfaces against the ordinary dangers of infection: will allay local irritation; and so these may be appropriately prescribed in every case of pain in the eye from foreign bodies. The yellow oxid of mercury he considers valuable as a local application in nearly all forms ulceration or abrasion of the cornea and conjunctiva. The tension of the eyeball must be noted in every case of injury, and if found slightly increased, a solution of eserin should be instilled, a saline purgative administered, and if the increased tension be accompanied by a sense of pain on pressure upon the globe, it is best to begin with salicylate of sodium or ammonium at once. Hot ablutions are often of great value in cases of irritation of the iris and ciliary body, whether due to constitutional or local causes. In cases of contusion, and in those cases of extravasation of blood from sneez-

ing, lifting heavy bodies, and from various causes of small blood tubes, a solution of pilocarpin promotes rapid absorption of effused fluids. This may be instilled into the eye or injected under the retrotarsal conjunctiva in doses too small to perceptibly affect the heart.

DR. FRANK ALLPORT, of Minneapolis, thought Dr. Reynolds had struck the keynote in certain phases of ophthalmic practice, in that he strenuously advocated the harmless treatment of the eye. He had seen so many instances of eyes that had been injured along the line indicated by Dr. Reynolds, that the paper appealed to him very strongly. The longer he practices ophthalmology, the more he feels the necessity of using mild and uninjurious remedies. He could not but believe that remedies such as the doctor had indicated in his paper that actually produced irritation of the conjunctival surface or of the epithelium of the cornea could be other than extremely injurious in cases of acute inflammation.

DR. WM. H. WILDER, of Chicago, could not agree with the essayist when he thinks that we should abolish the use of the stronger remedies in the treatment of diseases of the eye. They certainly have their use, and particularly in infectious cases, as gonorrheal ophthalmia, whether in the newborn or in the adult. The severer cases of trachoma should be handled without gloves. It is true, their treatment requires skill, but there is no reason why the general practitioner should not familiarize himself with the methods necessary for the treatment of all of these cases.

OBSERVATIONS ON SOME CRITICISMS OF SEROTHERAPY.

DR. PAUL PAQUIN, of St. Louis, Mo., read this paper. No department of therapeutics has called forth so much criticism as serotherapy. These criticisms have been of two kinds: Those based on scientific problems of biology, and secondly, those based on clinical effects and results. The author considered these separately at length. To show the most deleterious results of serotherapy, injudiciously applied, the author had conducted experiments in animals and man and analyzed the results. In a rabbit in good health the number of red blood corpuscles per cubic millimeter were 5,800,000. He injected 4 c.c. of pure horse-blood serum immunized, and three hours later the red blood corpuscles were counted again and they had dropped to an average of 3,900,000 per c.m., a loss of 1,100,000 per c.m. of blood. Eight hours later, 3 c.c. more of pure serum of another horse was injected, and within four hours the red blood corpuscles had been reduced to practically 2,800,000 per c.m., or 3,000,000 less than before any injection. At the same time the leucocytes had increased in large numbers. Practically, the same results were obtained in a man 35 years of age. The number of red blood corpuscles averaged 4,400,000 per c.m. before injecting pure horse-blood serum. Ten c.c. were injected in one dose, the patient never having received it before. Four hours later the red blood corpuscles averaged 3,800,000 per c.c. Six hours later they averaged 3,000,000. Again, in this instance, the white cells were enormously increased. In the experiments both in man and animal, in which the blood cells were diminished largely in number, the temperature declined slowly below the normal, and there were pronounced symptoms of depression. A phase of criticism is based on the idea that in using serum, some fatal or at least dangerous animal diseases, such as glanders and tuberculosis, may be transmitted to man. This is well founded. Glanders has thus been transmitted, if we are to believe the reports of the press, but this danger can be entirely avoided. As to the beneficial effects of serum, these depend unquestionably in a great measure upon increased phagocytosis. The serum increases the white cells whose duty it is in part to destroy microorganisms in tissues and their toxins, probably by a process of cellular digestion, or rather a diastatic neutralization. In a tuberculous man of 35 years, in which the white cells were less than 16,500 per c.m., they were increased to over 10,000 in seventeen days by the daily injection of 2 c.c. of antitubercle serum. The author obtained a similar result in a rabbit in which he had injected Roux antitubercle serum daily for three days, the dose being 1 c.c., also with other serums in other small animals.

DR. FRANK ALLPORT, of Minneapolis, read a paper in which he pointed out the relations which should exist between oculists and opticians. He advanced strong arguments in favor of licensing opticians to fit glasses. The fitting of glasses was not a trivial affair, but necessitated in many instances a thorough examination of the eyes by a properly equipped, specially trained medical practitioner.

DR. DUDLEY S. REYNOLDS, of Louisville, said it frequently happens that a neurotic person consults the ophthalmic surgeon with two or three, or perhaps half a dozen pair of spectacles in his possession, and on suspending the accommodating power of the eye and testing the state of refraction no glasses are needed.

DR. RYAN, of Galesburg, said that every practitioner who is doing more or less ophthalmic work had seen evidences of the injury done by traveling opticians and spectacle vendors. Every general practitioner should look at the eye, not as a machine, but an organ which performs a general physiologic function.

DR. R. HARVEY REED, of Columbus, Ohio, said that legal measures would soon be enacted in Ohio to prevent the optician from encroaching upon the field of the ophthalmologist. The instrument makers would also be included if the bill should become a law. The subject was further discussed by Drs. Wilder and Hale, of Chicago, and Dr. Balls, of St. Louis.

THE OPERATIVE TREATMENT OF JACKSONIAN AND FOCAL EPILEPSY, AS ILLUSTRATED BY SELECTED CASES.

DR. CHAS. B. NANCREDE, of Ann Arbor, Mich., read this paper. The cases reported by the author demonstrated what has been the experience of Horsley, Keen and other surgeons, namely, lack of permanency in results. The great difficulty is a reliable method of preventing adhesions. The removal of the lesion in cortical and Jacksonian epilepsy can only be regarded as palliative. The earlier the operation is done after the disease has become established, the longer the immunity. It is possible that if trephining is resorted to early, the operation in a few instances might prove curative, if a reliable method is devised to lessen the inevitable scar and to prevent adhesions between the membranes and brain. Operation is not dangerous in competent hands, especially when performed early.

A public address was delivered (by invitation) by DR. JOSEPH M. MATHEWS, of Louisville, Ky. Dr. Mathews selected for his subject

SOME NEEDED REFORMS IN MEDICINE.

He first dealt with specialism, according all honor to the specialist. Professors in medical colleges should educate students that the great object in medicine is to practice it; and yet we find blooming into special lines of work every day all over the Union, both in the cities and country, young men, without any special preparation either for surgery or for any other particular line of medical work, setting themselves up as learned men in special departments. The profession should call a halt. It should be impressed upon the minds of students that thorough preparation is necessary in order to be a specialist, and unless this is done specialism would be brought into disrepute. No man can be a specialist in any department who has not fitted himself and had experience in the general line of practice. Reform was needed in the appointment of medical men to fill places in medical institutions, such as asylums, etc. Too often petitions were circulated and signed in favor of this and that man, without taking into consideration professional qualifications.

Expert Testimony. This should be raised to a higher plane, and those who testify as experts should receive adequate compensation therefor.

Attendance at Medical Societies.—In the State of Kentucky there are 4,000 registered practicing physicians. Of this number about four hundred only belong to the State Medical Society. Dr. Mathews believes that this small membership obtained proportionately in the other States. The live, busy, energetic and most eminent practitioners attended medical societies.

Consultations. The old rule that applied to consultations does not hold good to-day. Specialism was not known until recent times. There has been a change in the order of things and practitioners of medicine have to meet the issue just as it is. To day a patient either belongs to the physician or to the specialist, and not to both alike. When a specialist recognizes that a patient does not require his special attention he should call a physician. Per contra, when a physician recognizes that a patient needs special attention he should give the patient to the specialist. Dr. Mathews then strongly condemned the endorsement by medical men of preparations, the composition of which they know comparatively nothing. A reform was absolutely indispensable in this regard.

Code of Ethics. This document needed no defence from him, as it stands open to the world. He did not believe there was a man or woman in the profession who could raise any objection to what is taught therein. The perfect gentleman, however, in his professional relations could control his actions without the Code and act with honesty toward his fellowmen, at the same time there is nothing in the Code to which honorable men could object.

Quacks. The State Board of Health of Kentucky had succeeded in driving out of the State within the last two years over eight hundred and fifty charlatans. How was this accomplished? By the concerted action of the medical profes-

sion and the representatives in the State Legislature. Dr. Mathews then paid an eloquent tribute to the good work that had been done by the former Illinois State Board of Health.

Dr. R. HARVEY REED, of Columbus, contributed a paper entitled

SOME PRACTICAL REASONS FOR EARLY OPERATION IN APPENDICITIS.

In an article on the "Surgical Treatment of Chronic Catarrhal Appendicitis," read by him before the Ohio State Medical Society in June, 1891, he referred to the practical uses of the vermiform appendix and expressed them by quoting the following couplet from an old poem:

"Everything can something do,
But, pray, of what use are you?"

At that time he drew the following conclusions, which he emphasized in this paper:

1. That the vermiform appendix is a useless rudiment.
2. That chronic catarrhal appendicitis is always dangerous and liable to be followed any time by hazardous and even fatal results.
3. That medical treatment is of little or no permanent value in this class of cases.
4. That the only safe and reliable method of treating chronic catarrhal appendicitis, and the only treatment that will promise permanent relief to the patient is the prompt amputation of the appendix.

It is the experience of Dr. Reed that delay increases the mortality record in these operations. Cases were then reported illustrating the importance of early operative interference, and the arguments of eminent surgeons advanced in its favor.

Dr. D. C. BROCKMAN, of Ottumwa, Iowa, followed with a paper entitled

OBSERVATIONS ON THE TREATMENT OF SURGICAL TUBERCULOSIS.

The author called attention to three remedies to be used in the treatment of tuberculosis, guaiacol internally, and iodine trichlorid and iodoform emulsion locally. While he does not believe guaiacol is a specific in tuberculosis, he thinks its judicious use will prove efficient against the septic condition which accompanies this disease. He next called attention to iodine trichlorid in vesical tuberculosis. In the management of tuberculous abscesses there was no treatment that could compare with the use of iodoform emulsion.

Dr. ELMER LEE, of Chicago, read a paper on the

TREATMENT OF PNEUMONIA WITHOUT DRUGS.

The principle which has guided the author in his experiments in the treatment of pneumonia is based upon a conclusion reached some years ago that the maintenance of the strength of the patient is the first requirement in the successful treatment of an acute disease. To preserve the resistance of the system against disease requires an understanding of two simple propositions: 1, how to support the embarrassed nutrition, and, 2, the proper force by which to aid in the removal of deleterious matter from the body. Following upon these two general principles we have confronting us fever to subdue, arterial pressure to overcome, congestion to remove and oxygen to provide for preserving the blood. The symptoms were next dwelt upon at length. As to the treatment of the disease, the author has recently instituted in his practice a sprinkle-bath, which he illustrated. A fountain syringe containing water of a temperature below the normal of the body is hung on the wall, the chandelier, or the bedpost, and by reason of a small sprinkler nozzle, fitted to the end of the tubing, the patient is watered as would be a bed of flowers in the summer time. First, the patient is placed upon a blanket or a rubber sheet and the front of the body sprinkled, then the patient is turned upon his face and the shower bath completed. Sprinkle-baths should be given to the patient every two or three hours during the day. Irrigation of the bowels constitutes the use of water in its third remedial capacity. The value of the irrigation is placed by the author in the second place of importance, as follows: 1, water introduced into the system through the mouth; 2, water introduced into the large bowel as an irrigation, and 3, water used upon the surface of the body. The use of water by the mouth as a remedy is accompanied with extremely small doses of medicine to meet the expectations of the patient and members of the family. Pneumonia cases treated by scientific hydratic measures are convalescent at the end of the first week. Complete recovery is proportionately shortened. It is the author's belief that this method of treatment is the quickest, surest and best management of pneumonia. This plan was only an outline of the general system of treating pneumonia by hydratics; each case must be managed and directed upon its individual merits.

CONSERVATIVE SURGERY IN THE TREATMENT OF HEMORRHOIDS.

By Dr. JOSEPH B. BACON, of Chicago. The author finds in looking over his records that but a very small per cent. of his operative cases have been purely internal or external hemorrhoids. Cases that are suffering or bleeding sufficiently to cause them to seek medical advice are those that have a mixed form of piles, where the anastomosing vessels connecting the external and internal hemorrhoidal veins have become varicose, and these dilated veins press upon the sensory nerve filaments over the inner border of the external sphincter muscle, causing pain and prolapse of the internal hemorrhoids. A segment of the varicose system of veins must be removed, one segment on each side of the anus being sufficient. If the larger tumors are removed, one at least on each side, the varicose system of veins is broken and the remaining varicosities are absorbed and disappear. Remove those hemorrhoids that are causing the discomfort together with the external or skin tags, and the patient is cured, and only a small surface of either skin or mucous membrane has been disturbed. The ligature, clamp and cautery, or crushing method, according to the choice of the surgeon, will answer the purpose. After the patient is convalescent, teach him the causes of his previous trouble and how to avoid congestion of the portal circulation, or overstraining of the general vascular system. This method of operating gives the best results, and if adopted generally would tend to restore the confidence of a much abused class of patients and give the general public greater respect for the science of surgery.

Dr. THOMAS O. SUMMERS, of St. Louis, read a paper on Leucocytosis—its Relation to Modern Therapy.

Dr. ALEXANDER C. WIENER, of Chicago, exhibited cases of spastic torticollis treated with extension apparatus combined with corsets.

Dr. GUSTAV FUETTERER, of Chicago, described a new method of treating gonorrhoeal infections of the knee-joint in which he had successfully used injections of oil of sandal wood. He employs the best preparation of this kind made.

CLINICS.

A clinic was given at the Postgraduate Medical School by Dr. J. B. Murphy before the members of the Society. Dr. Murphy did a cholecystostomy in one sitting.

At Rush Medical College, clinics were given by Dr. J. H. Etheridge and Dr. Fernand Henrotin. Dr. Etheridge did a laparotomy for hydrosalpinx on one side and pyosalpinx on the other; and Dr. Henrotin performed a vaginal hysterectomy for malignant disease.

Dr. Nicholas Senn, at his usual Thursday afternoon clinic in Rush Medical College, exhibited several patients upon whom he had previously operated for peritoneal tuberculosis. He next showed and expatiated upon the following cases upon which he had operated: Tubercular appendicitis; tubercular perichondritis; several cases of tuberculosis of the cervical glands; sarcoma of the breast; tubercular synovitis of the knee-joint; pyloric stenosis; pseudo-leukemia; a case of hernia operated on by the Bassini method; tubercular osteomyelitis implicating the phalanges of the toes; penetrating gunshot wound of the knee-joint, etc.

The following officers were elected for the ensuing year:

President, Dr. A. H. Cordier, Kansas City, Mo.

First Vice-President, Dr. Hugh T. Patrick, Chicago, Ill.

Second Vice-President, Dr. H. C. Eschbach, Albia, Ia.

Secretary, Dr. Geo. W. Cale, St. Louis, Mo.

Treasurer, Dr. C. S. Chase, Waterloo, Ia.

St. Louis was selected as the place of the next meeting.

SELECTIONS.

The Physiologic Effects of the Indulgence in Anger.—The *Medical Examiner* quotes from the *Journal of Hygiene* a vivid description of the results of bad temper. It says: We can readily understand the sentiment of the Latin line in our old copy-books, *Ira furor brevis est*, in the presence of this vivid portrayal.

The list of affections defined under "angina" in the dictionaries—for it has the same derivation as anger—and its modifications, as angina pectoris, is something startling, for it may be safely said that an uncontrollable, passionate disposition, individual or ancestral, is the seed from which most of these ugly conditions have sprung. Look for a moment at a man in a fierce rage: The muscles of his arms are tense, so that

his fists are instantly clinched, the muscles of the neck and chest so rigid that breathing becomes difficult and unnatural, and the circulatory system is temporarily congested. When such a mental state is frequently allowed unnatural sway over the body, it is not hard to see how the difficult breathing and inflammatory states of the various diseases which are grouped under the head of angina, and the constricting pain and spasm of angina pectoris have their origin. It sometimes happens that a man falls dead in a fit of rage, and it is said, perhaps, that he had a weak heart, which could not stand the strain imposed by his mental state. Nobody seems to think that this is but the culmination of a long series of such fits of madness, which have themselves caused the weakness in question. Another class of persons are slow to anger, but when aroused are so filled with resentment that they will brood over injury or injustice for months or years. They brood and brood over the occurrence until it becomes a mental canker, eating into the vitals, and this, if habitual in recurrence, will produce disastrous results. Still another class are fault finders. Perhaps they are seldom positively angry, but their minds are in a chronic state of turbulence in which they feel themselves injured. These people suffer from nervous diseases.

People of this description are not first-class selected lives. They become so-called cranks—abnormal creatures, and sooner or later do something or become victims of some condition which will cut short their life expectation.

Relapsing Sore Tongue.—Mr. Jonathan Hutchinson presented to his post-graduate class a case of the above named affection, as reported in the *Medical Press* for February 26. There were large abraded patches upon the surface of the organ, and these resembled a severe attack of herpes. Herpes of the tongue occurred chiefly along the margin and tip: herpes of the tip was exceedingly common. Sometimes these attacks supervened with such frequency that the patients were scarcely ever free from them. The history of the present case was that the disease had persisted off and on for twenty years. At intervals the tongue would be quite sound, but after some months a relapse would occur. The present attack, which had lasted for four months, was the most severe which the patient could remember. On examination of her teeth, one tooth was seen in which an amalgam stopping had been used. Mr. Hutchinson here remarked that he entertained great prejudice against amalgam stoppings in teeth, especially in mouths which were sore. In such cases he always insisted upon the amalgam being removed and gold inserted in its place. Dentists, he stated, would not believe that any harm arose from amalgam stoppings. But he was satisfied that in certain conditions some chemie solution of the amalgam took place. Most often the tongue became sore opposite the tooth in which the amalgam was present. Moreover, he had often found that patients could tell by means of a slight metallic taste in their mouths which tooth it was in which the amalgam had been placed. Again, he had often seen cases of sore mouth where all the symptoms had been relieved by replacing the amalgam with gold stopping. The pellicular condition of the patient's mouth was most interesting. In some respects the leucophakia somewhat resembled that seen in smoker's tongue, but more inflammation was present than was usually observed in the latter condition. It was worthy of note that the filiform papillae had disappeared over a large area. The patient, on being asked if any particular articles of diet caused irritation to her tongue, replied that anything "sharp" did so, and in this connection she instanced vinegar. She also avoided walnuts. Mr. Hutchinson was interested to find that she had herself discovered the irritating effect of walnuts. He pointed out that walnuts were especially harmful in these cases. The old, dry walnuts were possibly not much to be blamed in this connection, but the juice of the rind of the young, moist walnuts was especially irritating. He had seen many cases of sore mouths arising from this cause. Again, such patients should avoid all effervescent waters, and sugar in combination with vegetable acids was very harmful. The remedy for these cases was arsenic.

Extraordinary Longevity in a Family having an alleged Tuberculous Taint. The *Philadelphia Press* has the following item, which

we will be glad to have verified by the local medical faculty of Otsego County, N. Y.: "Probably the most remarkable case of longevity in Burlington, N. Y., is to be found in the Wilkinson family, the majority of the members being residents of Mount Holly. The ages of the eight persons now living are: Mrs. Martha Groom, 91 years; Priscilla Wilkinson, 88 years; Margaret F. Lamb, 84 years; Ann Curtis, 83 years; Mrs. Ruth B. Barton, 82 years; Lavinia Wilkinson, 79 years; Abel Wilkinson, 79 years; William E. Wilkinson, 77 years, their aggregate ages being 662 years, an average of 82 years. They are all well, active, possess the best of health, have sound minds, memory and understanding. There are many remarkable circumstances connected with the lives of these people, particularly the fact that both father and mother died at an early age, both parents being the victims of consumption. Abel Wilkinson, a Welshman, died in 1828, at the age of 48, and his wife Deborah, a German, died in 1832, at the age of 52. Not one of the children has had the slightest trace or symptom of that disease." The relation of tuberculosis to longevity form a vexed question with the life insurance leaders, and the latter as a rule steer clear of risks with a frank tuberculosis history. It is not sufficient that a "risk" is, at the time of examination, in a robust and assimilative frame of physique—if he have a frank history of tuberculosis—for it is by no means certain that some comparatively slight engrafted malady or accident may not before long overtake and demoralize the apparently robust physique. The pessimistic examiner will feel impelled to decline the risk. How the optimist may be expected to view the case may be judged from a report recently put forth by the capably and adroitly conducted New York Mutual Life Company. This report, which is in part at least the product of the pen of Dr. E. J. Marsh, a veteran medical director who has for years carried vast responsibilities for the mastodon companies, is addressed to the double question on the value (positive and relative) of family history and personal condition in estimating a liability to consumption. The closing remarks and conclusions of this report are as follows: While mindful that individuals with a very unfavorable family history have, as a rule, been rejected, and that, therefore, our experience has been to this extent limited, the statistics gathered by our later actuaries warrant the following conclusions:

1. That the history of consumption in any member of the immediate family increases the probability of its appearance in an applicant.
2. That consumption in a brother or sister is at least of equal importance as when it has occurred in a parent.
3. That persons who are under the standard or average of weight are much more liable to consumption than those above this standard. That the peculiarity of constitution which is indicated by the inability to take and assimilate a proper amount of nutriment indicates a susceptibility to phthisis, or at least is a reasonable suspicion of such predisposition.
4. That persons who exhibit a robust and well-developed body have little susceptibility to consumption.
5. That the personal condition of weight and robustness has far more value than the family history in diminishing the liability to consumption.
6. The evidence presented by a well-developed body may outweigh the suspicion attached to unfavorable family record.
7. That these influences of family history and personal weight are of the same grade for every age, and their importance is not lessened by the fact that the individual has reached middle life.
8. And as an eighth conclusion, and at the same, time *précis* of counsel to medical examiners, the report closes in saying: "In deciding upon the eligibility of an applicant for life insurance, in whose case there is a suspicion of future danger from consumption, his personal condition is of the first, and his family record of the second importance. Whenever he presents a robust physical appearance, with a weight at least equal to the standard or average as given in our tables, he may be accepted, notwithstanding any taint in the record of his family. In our experience such persons have a small liability to consumption, although not protected from it. If, however, his weight does not come up to the average, and he gives a history of consumption in brothers, sisters or parents, he is to be regarded as an unfavorable risk. This does not mean that all such persons are to be absolutely excluded from insurance, but each case must be carefully scrutinized, and the decision based upon the circumstances of occupation, character, past history, etc. When these are favorable, insurance should be given on terms most advantageous to the company, by limiting the amount or modifying the form of policy; when unfavorable, the applicant should be either postponed until he has gained sufficient weight, or else be absolutely rejected."

THE

Journal of the American Medical Association

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
 Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
 No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, APRIL 18, 1896.

THE ANNUAL MEETING.

"the sweet South
 That breathes upon a bank of violets."

Without fear of successful contradiction we may confidently assert that no previous meeting has had a better program, or at this date given earnest of scientific work of higher grade. The plan adopted for the past few years of choosing section officers by each section for itself, has been productive of the highest benefit. Those responsible for the management of the section, are workers in that section, thoroughly acquainted with their colleagues and their respective capabilities. The consequence is that there are few misfits in the section programs. The subjects assigned have fallen into competent hands, as the Spanish proverb has it: "The drum is in hands that know how to beat it." We may with every reason expect our ASSOCIATION work to take even higher rank each year.

The general sessions will be attractive. An interesting address may be expected from our President, "the old man eloquent" of the Pacific Coast: and from those high authorities in medicine, surgery and hygiene respectively, WM. OSLER, NICHOLAS SENN and GEORGE H. ROHÉ. One would indeed go far to find abler representatives of their respective branches in medicine.

Nor will the outside features of this meeting be devoid of scientific interest. We may expect something important from the meeting of such influential bodies as the American Academy of Medicine, the Association of Medical Colleges, and the Conference of State Boards of Examiners and Licensing Boards.

Fifteen years ago the ASSOCIATION met in Atlanta, under the Presidency of PROFESSOR THEOPHILUS PARVIN; our present President, PROFESSOR BEVERLY COLE, was present as the only delegate from Califor-

nia. DRS. DAVIS, GROSS, BALDWIN, HOOPER and TONER, former Presidents, were there, and also DRS. BRODIE, MARCY, DAWSON, BRIGGS and HIBBERD, who each became President. DR. LOUIS A. SAYRE was elected President for the ensuing year, and DR. R. BEVERLY COLE First Vice President. On motion of DR. E. SEGUIN, of New York, the metric system of weights and measures was adopted by unanimous vote, and a resolution from the Section on State Medicine, prepared by DR. STANFORD E. CHAILLÉ, recommended the substitution of "a periodical Medical Journal for the present volume of Transactions." An amendment to the by-laws was offered by DR. JOHN H. RAUCH providing for the acceptance of one delegate from the U. S. Marine Hospital Service. Thus it will be seen that the former Atlanta meeting was a history maker. Let us trust that at the close of the next meeting in Atlanta the results may show an equal advance.

The profession of the State of Georgia, Atlanta and the South generally will be present to welcome their guests with that hospitality so ingrained in their nature as to have become a traditional trait of Southern character. The season will be the best, and the delicious mountain air will impart new vigor alike to the hurried city specialist, the general practitioner of city and country, and as well the sleepy Rip Van Winkle, Jr. M. D., who comes forth when "laylocks blow" to seek the society of his fellows and gain a renewal of professional life.

Finally, we urge our members to go, and if the discussions by the Sons of Science are too exacting for a weary brain, let them remember that Atlanta itself is well worth looking at, for was it not at Atlanta that

"Thickest there the spear-heads gleamed,
 And the scattered plumage streamed,
 And the broken shields were tossed,
 And the shivered lances crossed,
 And the mail-clad sleepers round
 Made the harvest of that ground?"

MEDICAL CONFIDENCES AND PROFESSIONAL HONOR.

A recent trial in England has again brought to the fore a legal question that has been already referred to in recent issues of the JOURNAL (March 31 and April 11), and which is still unsettled by statute in many parts of this country, and apparently also in Great Britain, viz., the obligation of secrecy on the part of the physician as to facts obtained by him in his professional relations with his patients. It seems to be the general opinion that this is obligatory, but there appears to have been a difference of opinion in this instance, an eminent physician stating it as his belief that the violation of confidence was under certain circumstances fully justifiable. The rather sarcastic comments of the Judge on this opinion probably show the tendency of the legal mind and have been quoted with commendation by the medical press.

There is no question but that it is, and should be, a point of professional honor under nearly all circumstances to keep sacred professional confidences. One might say *all* circumstances without any qualifications, but for the fact that the law itself interferes with medical secrecy in the case of certain formidable and frequent infectious diseases, and this requirement opens the way for casuistry in several directions. A physician might follow the course indicated by the eminent physician above referred to and plead as an answer the public interest required it; were there no law requiring reports of cases of contagious diseases, would not a physician, on humanitarian grounds alone, be justified in reporting a case of malignant diphtheria, for example in case it were possible to protect the community by no other means than its publication? It is easy to suppose such cases as this, and they belong to the class in regard to which the physician must act according to his conscience, and take the risks his action may involve. It is a curious fact, in this connection, that a certain class of contagious diseases, the spread of which is one of the most important social questions in several points of view, is just the one in regard to which medical secrecy is most imperatively demanded and in which its violation would probably be most disastrous. There have been some damage suits that have fully demonstrated these perils.

On the other hand, it is doubtful whether courts of justice would protect a physician under certain circumstances in following the dictates of professional honor and his own conscience. In such a case, as that of the assassin of PRESIDENT LINCOLN any reservation of facts or non-committal conduct might be disastrous, and it is a possible question whether DR. MUDD was not to some extent a martyr to his professional ethical standard. Such cases are, however, too exceptional perhaps to be worthy of consideration; they are referred to only as possibilities, and as illustrating certain risks of the medical profession.

It has been said that the physician stands in honor in exactly the same relation to his patients as the priest who may receive their confessions. This statement requires the qualification that the former alone has to do with honor; the priest should have an entirely different and more exacting standard as regards the question of abstract right. The physician is not specially a guardian of public or private morals, and the obligation to him to rectify or prevent their violation is infinitesimal compared to that of the priest, and while on broad humanitarian grounds there may be in very exceptional cases an excuse for revealing what has been learned professionally, it must be remembered that every breach of confidence is done at the violator's peril, and that this applies as well to any, even implied, confirmation of what may be common gossip or report. DR. PLAYFAIR can not obtain the sympathy of the medical profession in his misfor-

tune if the statements of the lay press as to his conduct are correct.

Such instances only emphasize the need of legislation on this subject, such as is now being pressed before Congress for the District of Columbia. Such a law is now in force in New York, and possibly in other States, and there should be some general legalization of what the ethics of our profession demand. The passage of the law for the seat of government would make an excellent precedent for its extension to all United States courts, and every reader of the JOURNAL is respectfully requested to use his influence with his representative for its success.

THE AMBITION OF THE OPTICIAN.

It is quite certain that we are entering upon a prolonged period of controversy and even warfare with the opticians. It is, however, rather with a portion of the general class, who are persuaded to throw in their lot with the jewelers and spectacle vendors. Their aim is to be recognized legally and commercially as official refractionists, the physician, specialist or ophthalmologist being relegated to the position of one who deals only with so-called diseases of, and operations upon, the eye. In the State of New York a determined attempt is being made to secure the passage of a law to this effect, and with the well-known and pronounced sympathy with quackery upon the part of legislators, newspapers and the general public, it becomes evident, as we have said, that this is only the first showing of the cloven foot. If, as seems likely, the opticians will not succeed in New York the first time, they will try it again and again, and in other States also.

The claim of recognition as the official refractionists of the community is based upon a tissue of misrepresentations, ignorance and errors easily seen to be such by medical men of any intelligence, but which bear considerable plausibility from the lay standpoint.

Let us first acknowledge that in one respect their reasoning is by no means shallow or foundationless. This is that many physicians (so-called) after taking a six weeks' course upon the eye at some post-graduate school, go off and set up as specialists, and pretend to be able to treat eye-strain and all the conditions that attend or cause it. This appears to us a most glaring abuse, and our post-graduate schools should look sharply at their work and the presumptions that they authorize by these courses. At present they are open to grave criticism. One who has been a general physician is but little better fitted after six weeks of special study to do refraction work, than is a layman-optician after the same "preparation." An expert ophthalmologist can have nothing but contempt for the impertinence that makes such a claim. Few physicians are competent to prescribe for eye-strain with less than two years of special and earnest study.

But even this admission by no means justifies the optician in his own claim. One abuse or wrong can not justify another and a greater one. It only makes us look a little sharper for the beam in the professional eye.

The fundamental argument upon which MR. PRENTICE and his associates rely in their raid upon the New York Legislature, is that the treatment of eye-strain is simply a matter of mechanic optics—that all one has to do is to learn the static and dynamic refractive and muscular anomalies of the patient's eyes, and then apply glasses by an invariable rule. This, as all ophthalmologists know, is downright error and falsehood. It is never in a single instance true. The ophthalmologist who should carry on his practice in that manner would soon find himself without patients. His more discerning competitors, by the inevitable results of his own stupidity, would soon get his patients. Every case of eye-strain has medical bearings and significance, either negatively or positively, and must be prescribed for with a physician's knowledge and judgment. That this is not entirely recognized by the medical profession is no argument. The experts in such matters should be consulted; only their opinion is valuable. We have before us a circular from an optician who claims that "above (sic) 170 physicians now send us their patients." If this were only nine-tenths lie it would be bad enough, and would only argue against insufficient education on the part of these physicians—or against the giving of commissions by opticians.

We have left out of the count a fact which is painfully evident to all oculists. There is hardly a day that they do not see instances of blindness or ruined eyes simply because the patient relied upon optician's glasses, and (of course) the optician failed to recognize the glaucoma, paralyses, pareses, organic diseases of the eye or of its innervating centers pointing to systemic disease. A few malpractice suits would perhaps set this matter right, as in such cases opticians are as certainly liable for damages before the law as are physicians, and they should be made to suffer for their temerity and impertinence.

Admitting, for the sake of argument, that—optically speaking—refraction and prescription is all that is required to treat eye-strain, it still does not follow—far from it—that opticians are capable of diagnosing and prescribing for errors of refraction. We have heard oculists of the most trustworthy judgment and long experience say that out of thousands of glasses prescribed by opticians they have never yet seen a single one that was correct.

The entire matter resolves itself into an attempt on the part of a certain class of men to arrogate to themselves functions and duties without education or ability. All the laws of optics in the world can not teach medicine. Eye-strain is a disease (or symptom of

disease), and to treat disease requires a medical education. It is over again the same essential controversy as was once waged and fought through as regards the druggist and the physician. Civilization has settled that controversy, and must in the same identical way settle the present one. The optician stands in the same precise relation to medicine as does the druggist. We are glad to know that the better class of opticians have nothing but scorn for the impertinent attempts of some of their unworthy fellows to arrogate to themselves a public function without proper preliminary education and qualifications. To them we may look, it is hoped, to aid the profession in its opposition to this latest attempt at legalizing quackery. They should unite as once did reputable and conscientious druggists to put the seal of their condemnation upon a plan that can only bring them disgrace. They have a noble and highly respectable calling, but it is as distinct from that of prescribing for diseases of the human organization as is that of the druggist. The profession is deeply cognizant of the debt owed to the intelligent coöperation of both professions, so far as pertains to their peculiar duties.

Medical men should be alert to oppose this subtle and ill-designed scheme which can, if possible, only result in more pernicious abuses and bring incalculable harm to the world.

AN ANTI-VACCINATION CENTER SEVERELY AFFLICTED BY SMALLPOX.

The town of Gloucester, England, and its vicinity has been the scene of much popular excitement on account of an epidemic of smallpox. A riotous demonstration took place at the Cottage Hospital, at Oakridge, used for the treatment of cases of that disease, and arson was committed, the hospital being damaged to the extent of \$600. Seven persons were convicted; and each were sentenced to a year's imprisonment.

In February last, the assizes for the Winter Term should normally have been held at Gloucester and JUSTICE GRANTHAM attended at that town for this purpose, but such was not carried out. In his charge to the grand jury he stated that he had received a communication from the authorities in Gloucester to the effect that smallpox was prevalent in the city and had been so for some little time past. Although every step had been taken to prevent any spread of the disease he had been asked to authorize an order to be issued closing all the public galleries in the court, so that no one should be allowed to attend the assizes save those on business. This he deemed was a very serious thing to do, and the question occurred to him, whether he was justified in bringing together into a town, where disease was prevalent, persons from all parts of the country, of all ages and both sexes, and in all states of health. The judge, therefore, took steps the

result of which were that the assizes were ordered to be removed to Cheltenham. Since, however, this decision has been arrived at the judge observed that he was informed that in Gloucester there were many people who, for the sake of a better name, called themselves anti-vaccinationists, that was, they resented the opinion that generally prevailed in the country, and by persons in authority, that all children should be vaccinated. When, therefore, he heard that the local authorities refused to compel persons to have their children vaccinated he thought it was more desirable than ever to take the step which had been taken because there were in the town many people—children and adults—who had not been vaccinated. It may be after this that the authorities will take these remarks of the judge into serious consideration.

The following paragraph in the *New York Times* comments upon the effects of the anti-vaccination craze upon the afflicted town:

"Anti-vaccinationists in this country may well ponder on the experience through which the citizens of Gloucester, England, are now going. For years that city has been a center of the anti-vaccination craze, and so prevalent there was this particular form of idiocy that the law in regard to the employment of this safest, and most certain of all the prophylactics known to medical science has long been a dead letter. The local authorities refused to enforce it, and as a result, not only has a vast proportion of adults gone without any other protection than luck from the attacks of a loathsome and fatal disease but a whole generation of helpless children was allowed to grow up unguarded, and every school became simply an invitation to pestilence. Now the invitation has been accepted, and such an epidemic of smallpox is raging at Gloucester as has been rarely equaled in modern times, except among the savage tribes of Africa or Greenland. It was only a few weeks ago that the first case was reported, and already the infection has swept through the whole city. The hospitals are crowded to overflowing, business is at a complete standstill, churches and schools are closed, and toward the cemeteries moves an almost continuous procession of wagons laden with the dead. And yet, in circumstances like these, the anti-vaccinationists of Gloucester are as vehement as ever in defense and propagation of their doctrines. They hold nightly meetings, and as all the local papers except one refuse to print their imbecile arguments, they are placarding the town with hideous and puerile pictures of Death, using his dart as a lancet and vaccinating a child who struggles in the grasp of a policeman."

An item in one of the English journals, also, states that an isolation hospital will presently be built for the use of Gloucester, in five pavilions, at a cost of nearly \$50,000, inclusive of \$10,000 to be spent for extra roads, water supply, sewerage and disinfection plant. The experience of the town, which is not a large one, has been costly and humiliating.

THE TRANSACTIONS OF THE FIRST PAN-AMERICAN MEDICAL CONGRESS.

We have received many inquiries concerning the Transactions of the Pan-American Medical Congress, which was held in Washington in September, 1893. Some of the correspondents have been inclined to hold the late Secretary-General responsible for the

delay. From a letter received from that gentleman we gather the following points:

1. The manuscript of the Proceedings of the Pan-American Medical Congress was compiled by DR. CHARLES A. L. REED, the Secretary-General, and was transmitted by him, in accordance with law, to the Secretary of State, Washington, under date of Nov. 25, 1893—but little more than *sixty days after the adjournment of the Washington meeting. This act ended, absolutely, DR. REED's custody of and control over the Proceedings.*

2. The Congress then in session, by concurrent resolution directed that the Proceedings be printed and bound in cloth and that 4,000 copies be delivered to the Department of State for distribution. The publication thus ordered was done by the Public Printer under the direction of an efficient editorial committee of which the Secretary-General was not a member.

3. Complete advance sets of the printed sheets, without illustrations, were furnished the President of the Congress, DR. PEPPER, in September, 1895.

4. The complete mailing list of the Congress, embracing all registered members and foreign correspondents, was compiled by DR. REED in 1893, and forwarded to the State Department at the earliest intimation of the probable delivery to the Department of the printed edition.

5. Information received in February, 1896, from the Public Printer announced the completion of the work and its delivery to the State Department, under the frank of which it is to be distributed to members residing in the United States, Mexico and Canada.

6. The delay in the distribution of the volumes probably depends upon some unavoidable exigency in the departmental service, the officers of which have at all times manifested a cordial interest in the promotion of the work. Further inquiries should be directed to the Department of State, Washington, D. C.

It is thus clear that the responsibility for the delay does not rest with any of the medical officers of the late Congress.

OUR JOURNAL.

The two-year lease by which the JOURNAL became a tenant of No. 86 Fifth Avenue, Chicago, will terminate April 30, 1896. Although the JOURNAL has prospered even in these troubled times of financial depression, far beyond our hopes, yet the work has been done under many difficulties and annoyances. The two changes in lessors, made it almost impossible to obtain the satisfaction of any complaint, the damages by fire and water, the breakage of machinery whereby we were many times deprived of power, the unpleasant surroundings of the hall and the utter failure of the management to perform any of their verbal promises, made a condition hard to bear with equanimity.

We have, by direction of the Trustees, concluded a lease with the owners of the Occidental Buildings, 61 Market Street, whereby we shall in a few days occupy the third floor in a new fire-proof building, now nearing completion. In this building there will be much more room, and new machinery will be added. We shall purchase an electric motor to run the machinery, so that we shall

no longer be subject to vexatious delays, on account of failure of power. We are happy to state that the JOURNAL was placed in the mails with absolute regularity during the past year, but it is an eloquent testimonial to the industry and zeal of the mechanical department, for several times "night runs" were made, and many days of over-time were expended on account of accidents which we trust may in the future be avoided. The increase in growth of the ASSOCIATION membership, larger than in any two previous years combined, shows that the work of professional organization is rapidly being accomplished.

The business necessity of a permanent home for the JOURNAL, is one that becomes more and more urgent each year. As the plant becomes more extensive, and the business increases, the bad policy of paying rent will be apparent. This item of rent will probably increase from year to year until the ASSOCIATION directs the purchase of a suitable property. Some talk has been in the air about a change of the place of publication, but it is evident that should the final home of the JOURNAL be in one city or another of our country, the policy of owning our own building is one that of right should prevail, and is a question entirely apart from that of location, which indeed might be settled once for all by the vote of each member without discussion. This question at rest, then the ASSOCIATION can easily take the necessary steps to provide a fund for the purchase of property, the payment of interest and the gradual extinguishment of the debt. The present move should be the last move into a rented building. Next time we should go into quarters owned by the ASSOCIATION.

THE JOURNAL SPECIAL TRAIN.

There is but one special train from Chicago to Atlanta operated by the authority of the Board of Trustees of the ASSOCIATION, all others are imitations. Reserved space on this train may be secured at this office or of MR. J. C. TUCKER, Big Four office, 234 Clark St.

CORRESPONDENCE.

Popular Lunacy.

CHICAGO, April 9, 1896.

To the Editor:—In a recent editorial entitled "Popular Lunacy," you refer to the highly educated young woman of London who suddenly asserted her conviction that marriage was immoral and her intention to live in concubinage with a workman. In the following paragraph you say, "whatever may have been the actual condition of the woman the moral of the decision (made by the Commissioners in Lunacy) is this: Insanity must be of a definite type, no new forms are to be discovered, our knowledge of it is exhaustive. This is an opinion, that, however satisfactory it may be to the legal mind, can have no medical standing whatever, its mere statement is a *reductio ad absurdum* in itself." Herein, it seems to me, you have touched the cause of much of the real trouble in regard to expert testi-

mony in our courts, especially in cases of insanity. That the present system is outrageously defective will scarcely be denied by anybody but that any very speedy change may be anticipated is almost as hopeless. The legal mind is trained to have great respect for precedent and authority: to it the old things are the best: antiquity confers upon a custom an almost sacred veneration. A lawyer and a judge hunt for precedents, so far as possible for their decisions: their guides are to be found in the past. This is undoubtedly as it should be. Our whole judiciary system rests upon and owes its dignity largely to the venerable antiquity of its forms. The medical mind being scientific on the other hand, has or should have little esteem for mere authority: it cares little or nothing for mere precedent; antiquity rather provokes suspicion in it. It looks forward for new things and new ideas: new discoveries are its goal and the old is quickly forgotten so soon as the new is established. In a word the science of medicine is continuously advancing. Law is conservative, medicine, like all science, is progressive.

The trial by jury is an old and venerable custom, probably the best that has ever been established for the administration of justice. Its object is to elicit *facts* in a case and to award a man a verdict found by his *peers*. At one time insanity was so little known as a disease that nothing but a few *facts* could be predicated of it. A man who did certain things beyond all reason, who acted entirely unlike the majority of his fellows, who distinctly did not recognize the difference between right and wrong, and who showed by word and deed that he was incapable of knowing that his acts were crimes in the sight of the law, even though he were able to distinguish right from wrong, was adjudged insane. He was the victim of a gross form of insanity, and of such any body of laymen might form a decision. That was in the early days of mental science and when mental phenomena were as little known to men of science as to any average layman. The trial of insanity by jury was not then so anomalous a proceeding. To-day, however, the jury system, the old legal tests of insanity and the popular conception of the disease remain about the same, whereas the science of psychology, the knowledge of mental phenomena and the physical causes of those phenomena both in health and in disease, have made a tremendous advance. The old legal tests are entirely inadequate to-day, for there are many varieties of mental disease, many manifestations of the same disease that can not be tested by the old legal standards. Moreover, certain forms of insanity as we know it to-day can not be decided upon the basis of one or more isolated *facts*, comprehensive to a jury of average laymen, but must be decided only by the *opinion* of one who has had long experience and observation in the study of similar cases. As a simple illustration, the delusion of grandeur often manifested early in general paralysis would produce but little impression upon the mind of an average jurymen, and in the absence of more prominent symptoms he would be apt to smile at the credulity of the expert who having seen many cases with similar delusions, should endeavor to impress him with the importance of such delusion as an early sign of serious mental breakdown. Many of the sexual psychopathias and finer grades of mental aberration, including the whole list of monomanias are absolutely outside of the comprehension of the inexperienced jurymen. To expect such a jurymen, after sitting many wearisome hours in a box listening to the confused examination and cross-examination of a couple of loquacious lawyers and a number of biased experts, to form a clear scientific opinion as to the sanity or insanity of of the prisoner, is ridiculous in the extreme. Were I the unfortunate prisoner I would infinitely prefer having my jury consist of a class of first year medical students, for these would, at least, have had some slight observation of the possibilities and probabilities of disease. Were the verdict to be one of life or death, I would pray to heaven that only those who had made

a life-long study of mental diseases and knew them in all their various forms should constitute the jury and not a set of men who are totally ignorant of the subject, whose minds are confused and wearied by the wordy conflicts of opposing counsels and experts, and who now for the first time have probably heard of such a mental trouble of which I was suspected to be the victim. It is a travesty upon justice itself in our very courts of justice, to allow a body of ignorant men to pronounce a verdict upon a condition of which only the most experienced and subtle minds are capable of forming an opinion.

The diagnosis of insanity does not depend upon the presence or absence of a few isolated *facts* but it is an *opinion* which can only be found by a genuine expert after long, close and serious study of the case. Hence experts, in my opinion, should not be classed as witnesses, but should occupy a judicial position in the court.

Insanity, as we know it to-day in its many and varied forms, with its subtle and singular symptoms, its frequent objective and subjective phenomena, is not a matter for the decision of any body of mere laymen, any more than certain problems of civil engineering, certain phenomena of chemistry, certain questions of mining are for the decision of a promiscuous body of men gathered in from the street. A man's sanity or insanity should be decided by a commission of genuine experts, from whom there should be no appeal unless it be to another commission of experts, this commission to consist of the most learned and experienced in mental diseases, to be appointed in such a way as to be free from politics and to be remunerated in accordance with the dignity and seriousness of their labors. If such a commission decides that the prisoner is insane there should be no further trial of the case; if they declare he is sane, then he should be submitted to the usual civil trial before a jury of his peers.

I know that the spirit of our judiciary system is that every man charged with a crime shall be confronted by his accusers and given an opportunity to examine them in open court. But I claim that the spirit of the system is grossly broken when a man, suspected of so serious a matter as mental disease or charged with the same, is confronted by partisan experts and is sentenced by an inexperienced, unintelligent set of jurymen. The prisoner is suspected of being insane; for the time being, therefore, he represents some one form of the many abstruse and subtle forms of insanity; on the other hand the jury consists of a set of plain ordinary business men, they represent no knowledge whatever of insanity or any of its various forms: therefore, in the abstract sense and metaphorically speaking, the prisoner is not being tried by his peers. As he stands for a certain form of insanity, being suspected of such, his peers in the abstract, are those experts who know more about and are capable of deciding best all questions in regard to that form of insanity. As cases of insanity are tried in our courts to-day, they seem to me to be illegal proceedings and contrary to the spirit of our great judiciary system. The advances made in mental science during the last few years have lifted it, it seems to me, outside of the jurisdiction of our courts. The latter are for the administration of *common justice*; their function is to ascertain *facts* and to pass *sentence* upon the strength of those facts. All this a jury is capable of doing. Insanity, however, is not a question of mere common justice, it is a physical and metaphysical aberration which must be *discovered, recognized and granted a certain amount of palliation*; it is not always a bald fact readily discernible by the average man, it is a most *subtle phenomenon* which only the most experienced can detect: the decision of it can only be justly made by those who are capable of forming the most accurate *opinion* in regard to it. This, only a special commission of learned experts is capable of doing.

L. HARRISON METTLER, M.D.

Poisoning by Acetanilid and Bismuth.

BRODNAX, LA., April 13, 1896.

To the Editor:—I note in the *Medical Brief*, April, 1896, an article taken from your splendid journal, written by Dr. C. W. Rook, in which he gives the details of these cases of poisoning, one death, from the use of equal parts of acetanilid and bismuth subnitrate. The infants were two and four days old. Without a doubt acetanilid is a powerful drug and should be used with care, but I think the doctor has hardly followed the formula given in the *Virginia Medical Monthly*. I think it is about as follows: acetanilid and boric acid equal parts. (This powder is named by Dr. Burgess of Tennessee, "boralid.") When used on tender skins, as infants, the formula recommended is a bulk of bismuth subnitrate equal to both the others, viz., boric acid and acetanilid each 1 part, bismuth subnitrate 2 parts. It will, no doubt, be noted that in dressing pustular eruptions twelve to twenty-four hours should elapse between dressings. In the cases either by the doctor the dressing in one was reported several times in twenty-four hours, this case died. In the other applied only once, it recovered. In the burn, "every four hours for twenty-four hours," supposable pure acetanilid. After several years experience with it in many ways I am convinced it is safe in 99 per cent. of cases. I have used it since its first appearance in aborting chills, then in the different skin diseases under my care. Given internally I have to record six cases of slight cyanosis in children under eighteen months.

Idiocyncrasy has much to do with its untoward effects. I have before me a report of an adult taking 5 grains, with "unpleasant cyanosis" following. In the *Medical Brief*, January, 1896, p. 86, I see "120 grains taken in six hours (8 doses of 15 grains each), recovery in sixteen hours." No treatment recorded.

Now, while acetanilid is set down as a heart depressant the writer in above article says "heart and respiration nearly normal."

With 120 grains ($\frac{1}{4}$ of an ounce) in a man 26 years old and "heart and respiration normal" there seems to me a screw loose as to the effects usually asserted, heart depressant.

Dr. Blackwood of Philadelphia in the October *Medical Summary*, warns against the use of the drug, within twenty-four hours of administering calomel. In subsequent numbers of same journal will be found letters from several physicians who have for several years used both drugs in conjunction or within a very few hours with no bad effects.

In isolated cases it might produce unpleasant effects, but what drug, potent for good, has not the same record? Cocain, chloroform, opium, even the "sheet anchor" quinin; the mild and ever present Dover's powder has in several instances in my practice produced most distressing urticaria. This is not intended as a "special pleading" for the use of the drug as a dry dressing. There are others which may be safer, but none which have so few faults or so many good qualities. One of these last, it seems to have an affinity for pus; cleaning and deodorizing foul ulcers as well as small pimples; the second application in many cases being all that is required to cure. One very severe case of pustular eruption covering half of the body of a woman came under my care. It more resembled smallpox than anything else. These were cleaned out by the first application of the powder and only two or three applications were needed to cure entirely.

Believing in my practice so far that the drug is a safe remedy, I would not apply it to a very large denuded surface pure or even half and half. I also believe that pitting in smallpox might be prevented, as also the distressing pain and smell of the disease, as well as its contagiousness controlled by "boralid." The backwoods doctor has not the opportunity of trying a new remedy on a number of cases at a time but has to go slowly, compare and study out effects. I have used acetanilid in various combinations in a variety of troubles in not less than 1,500

cases, and except the six above named have yet to see the first severe unpleasant effect.

At the same time it is not out of place to watch the effects of any new drug on a patient; in very young ones to *dilute* skin applications the same as those exhibited internally, and to be there to stop its use if trouble ensues. It is my common practice when administering any new drug, or to new patients, to stay with them from one to six or eight hours and watch its effects. This is perhaps rather "old timey" and does not show up the "busy doctor" exactly—but it is safe—and I find I lose nothing by it.

DR. BEN H. BRODNAX.

Bony Union in Fractures of Neck of Femur— A Question of Priority.

MINNEAPOLIS, MINN., APRIL 11, 1896.

To the Editor:—In Dr. Hamilton's Columbus address published in the *JOURNAL* of April 4, Dr. Mussey is stated to have been the first to demonstrate the possibility of bone union after inter-capsular fracture of the hip joint. I have for many years understood that this honor belonged to my dear old friend, Dr. Phineas Spalding of Haverhill, New Hampshire, who is now past 97 years of age, and whom I had the pleasure of visiting a month ago. While I was living at Haverhill fifteen years ago, Dr. S. related to me the circumstances of this first case, and as I find an account of it in the "The Spalding Memorial and Personal Reminiscences," which may interest the *JOURNAL* readers, I venture to transcribe and enclose it.

Very Respectfully, EDWARD J. BROWN M.D.

"During the sixteen years I remained at Lyndon (Vermont) I had a great amount of practice in the neighboring towns in all the branches that pertain to a physician's life. Being the principal surgeon and consulting physician I had a good opportunity not only to become acquainted with the most important cases of sickness, but also with the views and practice of my professional brethren. Very many cases came up of great responsibility, and I will relate one, because I believe that it was a benefit to the profession, being a new departure at that time from the established mode of treatment:

Governor Cahoon, of Lyndon, fell sixteen feet, in his mill, producing an intercapsular fracture of the hip joint. I had been taught by Professor Mussey, and from the writings of Sir Astley Cooper, of London, that fractures of this character would not admit of ossific, only ligamentous union, on account of the nature of the parts; and a person suffering such an accident must necessarily be a cripple. After being perfectly satisfied as to my diagnosis, I stated this to Mr. Cahoon, and read to him the different authorities on the subject. I then said to him, if I were injured in this manner, I should make appliances and try for a perfect cure, but that it would require ninety days to give the limb a fair chance for ossific union, and perfect rest, without which it would not take place. He replied, on account of a pulmonary difficulty he could not submit to such a confinement. I therefore fixed the limb as well as I could, and left him. After a few days the limb shortened three inches and the foot very much everted outward. Mr. Cahoon then sent for me and said he would rather die than remain a cripple for life, and he would submit to any treatment I thought best. I therefore made my appliances with an apparatus of my own invention, and watched the case with a great deal of care; and at the end of three months had the satisfaction of seeing a perfect cure. As this was so important a case in surgery, I felt it a duty I owed the profession and the world, to publish it, and therefore wrote an article in the *New England Medical Journal*, printed at Boston, October, 1827, giving a full history of the case, my mode of appliances, and my reason for disagreeing with former authorities. Mr. Cahoon lived about ten years longer and no one would have supposed by his walk that he ever had a fractured limb, and he afterward died of consumption. I made an examination of the joint, found the bone had been fractured according to my diagnosis and that there was a most perfect union. This examination I also published in the *Boston Medical and Surgical Journal*.

I am now of the opinion that if this case was not the first one where a cure of fracture within the capsular ligament was perfect, that it was the first case published, and the reasons given why under favorable circumstances we may hope for a perfect union of the bones. Several years after this Dr. Mussey carried a thigh-bone to Europe and showed it to Sir Astley Cooper,

who acknowledged his error in his former teaching, and now in all our hospitals in this and other countries, the doctrine is fully established."

Toxic Effect of Antitoxin.

SHULSBURG, WIS., April 11, 1896.

To the Editor:—The account of the death of a child from a prophylactic dose of antitoxin, in the *JOURNAL* of April 4, makes me desire to put on record a case similar in its action although death did not occur. The facts are as follows: February 4, I was called to see Henry Snyder. Found him and his five-year old daughter affected with a severe type of diphtheria. I injected the father with a 1500 units and the daughter with a 1000 units strength, Behring's antitoxin, with good results. Mrs. Snyder, who was nursing her husband and child, complained some of her throat and wanted me to examine it. I found the arches of the fauces a little red, nothing more, pulse and temperature both normal, appetite good. She was apparently in good health, except being fatigued from broken rest. As she was the only dependence for a nurse to take care of her husband and child, I advised her to take a prophylactic dose of antitoxin; she consented. Not having the prophylactic dose, I used No. 1, green label, 600 units strength, Behring's, Op. No. 253. A few moments after the injection she complained of feeling faint, her pulse went up to 100, almost imperceptible at the wrist. She became very pale, feet and hands cold, respiration hurried and shallow, pupils dilated. Face was covered with a cold perspiration. I laid her down with her head low and administered stimulants. It was six hours before she rallied so she could sit up and twenty-four hours before she felt herself again.

Place of injection was over right breast and every aseptic precaution was taken. I noticed symptoms of the same nature, not so severe, from the use of a prophylactic dose of antitoxin in a child of 9 years. It seems that antitoxin is apt to produce toxic symptoms in the well.

C. C. GRATIOT, M.D.

Association Badge.

NORTH MINNEAPOLIS, MINN., April 7, 1896.

To the Editor:—In the last number of our *JOURNAL* I notice a short article from Dr. Blaisdell on the "Association Badge." I have spoken of it a number of times during the last few years, asking myself and others of the ASSOCIATION members: What had become of our badge? It has been so long since it was decided and I think voted upon in the ASSOCIATION that we were to have it that I have really forgotten at what meeting it was acted upon, whether Detroit, Chicago, Washington, Richmond, or where. I think Dr. N. S. Davis, of Chicago, introduced the subject, but am not sure. I have grown old since that time, now nearly 74 years, and I feel as though if I am to see a badge it will have to be coming along very soon. A great many of our brethren have already "crossed the river" since the action was taken, and many more will go, I am afraid, before we get the "badge"; unless prompt action be taken. The Atlanta meeting will soon be in session, and some *more definite* action should be taken in the matter.

Very respectfully, A. A. NOYES, M.D.

Bone Grafting.

MILWAUKEE, WIS., April 11, 1896.

To the Editor:—In your issue of April 4, p. 692 is an extract from the *Medical Press and Circular*, in regard to "An Unusual Case of Bone Grafting. Permit me to say that this is another illustration of the old saw, "A prophet is not without honor, save in his own country" and to call your attention to an article on this subject by Professor Senn, in the *Am. Jour. Medical Sciences*, September, 1889.

Yours,

G. J. KAUMHEIMER, M.D.

"She Has Suffered Many Things." Another Case.

NEW YORK, April 13, 1896.

To the Editor: I can not allow Dr. Cory and Dr. Cutter to carry off all the honors in their rivalry over the possession of patients with multitudinous ills. An old bachelor from down East who comes to New York with a new ailment every few months asked me in despair how many diseases it was possible for a man to have. "About two thousand," I answered. "Oh, Lord!" said he, "then I have fifteen more to go."

Yours truly, ROBT. T. MORRIS, M.D.

BOOK NOTICES.

Diagnosis and Treatment of Diseases of the Rectum, Anus and Contiguous Textures. By S. G. GANT, M.D., Professor of Diseases of the Rectum and Anus, University and Woman's Medical Colleges; Rectal and Anal Surgeon to various Hospitals, etc. With two chapters on "Cancer" and "Colotomy" by HERBERT WILLIAM ALLINGHAM, F.R.C.S. Eng., Surgeon to the Great Northern Hospital; Assistant Surgeon to St. Mark's Hospital for Diseases of the Rectum, etc., London. One Volume, royal octavo, pp. 400. Illustrated with 16 Full-page Chromo-lithographic Plates and 115 Wood-engravings in the Text. Extra cloth, \$3.50 net; half Russia, gilt top, \$4.50 net. The F. A. Davis Co., Publishers, 1914 Cherry Street, Philadelphia: 117 W. Forty-second Street, New York: 9 Lakeside Building, Chicago.

The author is to be congratulated on his careful adherence to the accepted classification of his subject, the number of his original illustrations, and his book generally: for it is a really valuable contribution to the literature of the subject. The latest authorities are suitably mentioned, and the book is not burdened with antiquarian or historic matter.

The author is of opinion that railway employees are peculiarly liable to contract rectal diseases, and states that 75 per cent. or even a larger proportion of all railway employees who have been running on trains for a term of five years or more, suffer or have suffered from some disease about the rectum and anus. The percentage seems large, but Dr. Gant, without giving exact language, quotes several authorities who are said to hold the opinion that the percentage is much larger. But there is reason to believe that a great part of this alleged disease in railway employees is rather due to neglect and lack of proper facilities for bath and ordinary cleanliness than to any etiologic factor inherent in their occupation. To them even more than to "England's king" the injunction of the school of Salerno applies: *Ne mictum retine, nec comprime for-titer anum*.

The portion of the work contributed by Mr. Allingham constitutes a very valuable addition, and the whole will be a welcome addition to the library of the practitioner.

The Psychology of Attention. By TH. RIBOT, Professor of Comparative and Experimental Psychology in the College of France. Authorized Translation. Third revised edition, cl., pp. 115, price 75c. Published by the Open Court Publishing Co., Chicago, Ill.

This is an effort to present the subject in a more complete form than has been done anywhere else, although it is really little more than a suggestive sketch and far from complete at that. However, the renown of the author commends it to the respectful consideration of all interested in psychology, and while it is not free from weakness of style, such as obscurity and abruptness, it succeeds in directing the reader along lines of pertinent and fruitful observations and, on the whole, it gives a good general conception of the subject. It is divided into three chapters headed 1, spontaneous attention, 2, voluntary or artificial attention, and 3, morbid states of attention.

Summary: Attention is an exceptional abnormal fact which can not last a long time. It is a momentary provisional state of mind. It is not an even operation, but intermittent. Voluntary attention is the product of civilization and previously

did not exist or did so by flashes and for short intervals. It first began in women, as they were the first to do labor without immediate attraction. The whole problem is a question of inhibition. Bodily movements are indispensable, necessary factors not effects. Its physical concomitants are vaso-motor, respiratory and motor (expressions). It is accompanied by local hyperemia of certain parts of the brain and quickens circulation in the nervous substrata which minister to it. Work is the most manifest form of attention. Such are Ribot's views. Our own definition would be that attention is the act of specialization demanded by personal or self-interest in the presence of a multiplicity of interests, and is the *sine qua non* and prerequisite to progressive intellection. It equals knowledge directed *plus* incentive *plus* brain tone *plus* brain capacity *plus* form of environment. It is an exaction of civilization rather than a product.

The National Dispensatory, with Supplement embracing the New Edition of the National Formulary. The National Dispensatory. Containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopeias of the United States, Great Britain and Germany, with numerous references to the French Codex. By ALFRED STILLE, M.D., LL.D., Professor Emeritus of the Theory and Practice of Medicine and of Clinical Medicine in the University of Pennsylvania, JOHN M. MAISCH, Pharm.D., late Professor of Materia Medica and Botany in Philadelphia College of Pharmacy, Secretary to the American Pharmaceutical Association, CHAS. CASPARI, JR., Ph.G., Professor of Pharmacy in the Maryland College of Pharmacy, Baltimore, and HENRY C. C. MAISCH, Ph.G., Ph.D. Fifth edition, thoroughly revised in accordance with the new U. S. Pharmacopeia (seventh decennial revision) and embracing the new edition of the National Formulary. In one magnificent imperial octavo volume of 2025 pages, with 320 engravings. Cloth, \$7.25; leather, \$8. With Ready Reference Thumb-letter Index, cloth, \$7.75; leather, \$8.50. Lea Brothers & Co., Publishers, Philadelphia and New York. 1896.

Not long since, see JOURNAL (Feb. 17, 1894), we noticed the magnificent new edition of the National Dispensatory. We are now furnished the supplement to the volume, which consists of a national formulary of unofficial preparations. This is in the nature of a "companion" to the pharmacopeia, inasmuch as it gives the formulæ of many preparations once, but not now, official, many others not yet recognized, and still others that were originally private, but now in common use. It will be noticed that elixirs, fluid extracts and emulsions furnish a large portion of the work. We question the propriety of furnishing formulæ for artificial mineral salts and waters, while there is no question of their enormous consumption both in this country and in Europe, yet in the latter countries the imitation article must be sold as such.

This formulary contains many things of great use to the practitioner, such, for instance, as battery fluids for the various kinds of battery, kunyss, mucilages, etc.

No preceding revision of the Pharmacopeia was received with so little criticism as the pharmacopeia of 1890, but still there are many preparations in use which are not included. The "unofficial" formula is therefore a necessity to the practitioner and pharmacist.

Fear. By ANGELO MOSSO (of Turin). Translated from the fifth edition of the Italian by E. LOUGH and F. KIESOW. Authorized translation. 8vo, cl., pp. 278. London, New York and Bombay: Longmans, Greene & Co. 1896.

In this book we have an interesting physiologic or psychologic study of the emotion of fear. The contents are as follow:

"How the brain works; reflex actions and functions of the spinal cord; the brain; the circulation of the blood in the brain during emotion; pallor and blushing; the beating of the heart; respiration and oppression; trembling; the expression of the face; the expression of the forehead and eye; the physiognomy of pain; a few phenomena characteristic of fear; fear in children; dreams; fright and terror; maladies produced by fear; hereditary transmission; education." The

Italian style has been so faithfully preserved by the translators that it makes quaint though very elegant English. We quote a sample from page 213:

"A FEW PHENOMENA CHARACTERISTIC OF FEAR.—The edifice of the human body may be compared by those studying its chemical properties to a vast manufactory of which every corner and every door bears the inscription 'No Admittance.' The curiosity of the public could not be greater: fain would they force an entrance, for all know that the most marvelous things are fabricated therein—wonders which no human hand, no industry can produce.

"The workmen in this factory are very small—marvelously small—invisible to the naked eye, and so tightly pressed together that they sometimes resemble the cells of a beehive, and have on this account (perhaps) received the name of cells. Life proceeds entirely from these workmen, whose confederation is so perfect that not one can be touched without the others at once becoming aware of it.

"The edifice is somewhat weak in parts, and here one might easily force an entrance and make a wide breach; but this violence would avail us little, for when we break into the building the machines stop, causing such disorder and confusion that we are quite bewildered. We hear a whirring and throbbing, the pipes burst, the fluids are spilt, the pumps stop, the valves open—then all grows cold and still; and this is the strike which we call death."

The author has made his book thoroughly entertaining, and his clinical descriptions of fear as observed in various types and conditions are life-like. In conclusion he urges as *the* remedy above all, education.

PUBLIC HEALTH.

To Prevent Introduction of Communicable Diseases.—A law was passed in Michigan in 1895 which provided, under penalty, that no person sick with cholera, smallpox, diphtheria, scarlet fever or any [other communicable disease dangerous to the public health, no corpse of a person dead from one of the above named diseases, or from any other communicable disease dangerous to the public health, and no article which has been infected or is liable to propagate or convey any such disease, shall come or be brought into any township, city or village in Michigan, without the special permit of the board of health or of the health officer of any such township, city or village, and then only under the supervision of the health officer of such township, city or village.

Child Labor Certificates and Boards of Health.—In the lower house New York legislature a bill has been passed, by a practically unanimous vote, providing that no child under 16 years of age may be employed in any factory or store unless it holds a certificate from the Department of Health, accurately describing it, and the Health Commissioner is satisfied that such child is physically able to perform the work which it intends to do. Relating to the sweat shops, the bill provides that when any article is found by the inspector to be made under unclean or unhealthy conditions he may, with the consent of the local Board of Health, indelibly brand upon such articles the words "tenement made." A further section makes landlords responsible for the existence of sweat shops and allows them to dispossess tenants.

Aberdeen New Epidemic Hospital.—The Edinburgh correspondent of *Sanitary Record* writes that the extensive additions and improvements which have been carried out at the Aberdeen City Hospital are now completed, and the formal opening ceremony took place on December 21. In round figures, the new works have cost \$100,000. The administration block, which is situated in the center of the group of buildings, with two pavilions on each side, has undergone an entire rearrangement, including additional servants' accommodation and a kitchen fitted up with all the modern appliances for cooking and heating. The enlargement of the wards has been accomplished by extension of Nos. 2 and 3, so as to provide additional accom-

modation for 18 beds in each, and now making over 100 beds in the institution. The pavilions are of one flat, and each of the wards is 16 feet high, 18 feet long, and 24 feet wide. The whole of the original buildings were built in concrete, but the new additions are of granite. The extensions necessitated a complete rearrangement of the grounds, which now cover something like seven acres, and have been laid out attractively in flowers and shrubbery. The whole of the front of the grounds has been so planned as to front Urquhart-road on the north side, in place of the south, that thoroughfare having been laid out since the hospital was originally built. A new gateway and lodge to Urquhart-road has been constructed, and the execution of this portion of the scheme necessitated the knocking down of the old offices and substituting new premises to serve both the internal and outside requirements of the hospital. This block has been fitted up with all the latest appliances for washing, ironing and disinfecting.

Anti-alcoholic Teaching in the Public Schools of New York.—An effort is being made by the Department of Public Instruction of Brooklyn to obtain the repeal of certain objectionable features of legislation that compels the use of anti-alcoholic textbooks in the public schools. The following is a portion of the resolutions, recently adopted by that department, pointing out the doubtful utility of compulsory legislation in the interests of any class of social reformers: "The method of teaching is not sanctioned by experience, and many of the statements made in the books are of more than doubtful scientific character. The law was passed at the solicitation of persons who, without training, experience or teaching, assume to dictate to scientific men what they shall say in scientific works, and experienced teachers how they shall teach. This law is the entering wedge of a species of legislation that would turn the public school system of the State over to the advocates of schemes and reforms. The purpose of the public school system is not to promote the schemes of any class of social reformers, however admirable they may be, but to train up men and women of strong minds, firm wills and robust bodies, capable of forming their own rule of conduct. The law takes from local authorities, and from those who have had pedagogic training and experience, at least in part, the right to determine the studies, text-books and methods of teaching in the schools for whose administration they are responsible. The enforcement of this law in the schools of Brooklyn involves the expenditure of a large sum of money that is needed for useful purposes; will dissipate the mental energies of our children; will impair the forces that make for true education, and will in many cases promote the vice it is sought to discourage."

Alleged Fever Increase in Fully Sewered Districts Controverted.—The editor of the *Sanitary Record* points out the fallacy of the argument seeking to prove that the Metropolitan main drainage system of London is responsible for a large increase of fever. He says that there are those who accept the up-growth of special fever hospitals as a proof that in earlier times these hospitals were not found necessary, but that since the formation of the main sewerage scheme such institutions have sprung up, and are now overcrowded, appears startling. It would be impossible to dispute this statement, for statistics place the matter beyond controversy. Nevertheless, statistics are fallacious and require interpretation. "In the pre-main-sewer days, typhoid, scarlatina, and other fevers did not crowd our hospitals, or cause a direct drain on ratepayers' pockets, because ratepayers died of the disease in quiet obscurity. The diseases were rife, though not much was said about it in lay circles, simply because we had no compulsory notification laws. A great laxity prevailed as regards the signing of death certificates, so that the returns of the Registrar-General are of little real value in a question of this kind. Even after special legislation had been passed, matters were not greatly improved,

Those who have studied this phase of sanitation know well that in the early days of the new order of things notification was very imperfectly observed, it being but indifferently understood by many medical men, and much dreaded by the general public. Now, however, there is greater stringency on the one hand while, on the other, the people are beginning to understand the advantages of notification, and even of isolation. The net result is increase of recorded fevers subsequent to main sewerage, for statistics can only take account of registered facts. Then, again, since sewerage came in, we have had a steady augmentation of population coinciding with a phenomenal aggregation of the people within the metropolitan area, as with all other large towns. Need we wonder, then, at our crowded hospitals? All this seems very simple, yet it is as well to expose fallacies of statistics, for now that notification is being carried out with an approach to conscientious accuracy, and that the people are growing less afraid of hospitals, the want of accommodation is daily becoming more apparent. It is essential that the necessary demand for more and improved isolation hospitals should not be construed as indisputable evidence of the failure of modern sanitation. Statistics are, unfortunately, often pushed forward to bolster up wrong doctrines: it can not be too clearly pointed out that figures, however accurate they may be, are only of relative importance, and unless explained may prove exceedingly dangerous in the hands of ignorant people or interested individuals. Although it may at first seem contradictory, the fact that more and also larger isolation hospitals are required, is proof that the true value of hygiene is gradually becoming better perceived.

Sanitary Reforms Followed by Reduction in the Mortality by Fever and Tuberculosis.—Dr. Rabagliati, health officer for Bradford, England, addressed a large public meeting on the subject of "The Great Waste of Infant Life." In the course of his argument he adduced the statistics of his town to show the influence of the great public improvements that have been put in during the last fifty years over certain features of adult and infant mortality:

"Beginning with the year 1850," he said, "that between that year and 1855, the loss of life from fevers or zymotic diseases was 5,243 per 1,000,000 of the population per annum, while the rate was now 2,700, the decrease having gone on continuously with the development of sanitary reform and a very noticeable feature of the improvement was that the fevers of the earlier period having mostly stricken children of tender years, the chances of children reaching maturity had been greatly increased by the improvement. Strange to say, however, in men from the ages of 35 to 65 the mortality was rather greater than less than it was fifty years ago, and between these ages the expectation of continued life has not improved at all. The diminution in consumption was very striking. In 1868 or 1869 figures for an earlier date he had not been able to obtain—the deaths from consumption numbered 2,500 per 1,000,000 per annum, while the present rate of mortality from this cause was 1,400.

"But while there were improvements in these two important classes, the deaths from diseases of the respiratory organs were very considerably increased in proportion to the growth of the population, the deaths from cancer had doubled in one generation, and there had been a considerable increase in recent years in deaths from apoplexy. They might feel some alarm at the increase of cancer, but it was pleasant to find that the gain in the consumption rate alone was at least twice as much in total as the increased death from cancer. He would lay down that night the dogma that the question of illness or health depended upon three things—air, food and exercise. There were other matters to be considered, perhaps, but they were trivial by comparison with these three. Accidents were the cause of some deaths, but of the 173,000 which he had referred to, only 6,000 were due to accident, and it was worthy of note that, owing to the efforts of governments to protect the lives of the people, deaths from accidental injury were rather fewer proportionately now than they were forty years ago. Bronchitis had developed very much as a cause of death, although there

was no evidence to show that the climate was any worse. The only way to combat this development was by keeping the body in such a state of health that it would be able to resist the ordinary climatic variations."

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Ohio: Dayton, March 1 to 31, 4 deaths.
Alabama: Mobile, March 28 to April 4, 1 case.
Arkansas: Fort Smith, March 28 to April 4, 1 case, 1 death.
Louisiana: New Orleans, March 28 to April 4, 85 cases, 21 deaths; Shreveport, March 28 to April 4, 16 cases, 2 deaths;
Tennessee: Memphis, March 1 to 31, 19 cases.

SMALLPOX—FOREIGN.

Dublin, March 21 to 28, 3 cases.
Rio de Janeiro, February 22 to 29, 12 cases, 7 deaths.
Birmingham, March 21 to 28, 1 case.
London, Eng., March 14 to 21, 43 cases.
Tuxpan, March 14 to 21, 1 death.
Paris, March 14 to 21, 1 death.
Odessa, March 14 to 21, 11 cases, 4 deaths.
Acapulco, March 21 to 28, 2 cases.
Calcutta, February 22 to March 7, 3 deaths.
Buenos Ayres, January 1 to 31, 33 deaths.
Madrid, March 17 to 24, 12 deaths.
Bombay, February 25 to March 19, 119 deaths.
Southampton, March 14 to 21, 1 case.
Alexandria, February 26 to March 4, 2 deaths.
Moscow, March 7 to 14, 1 case, 1 death.
Trieste, March 14 to 21, 4 cases.
Naples, March 19 to 23, 15 cases, 5 deaths.
Prague, March 15 to 21, 8 cases.
Buda Pesth, March 11 to 25, 6 cases, 1 death.
Montevideo, February 15 to 22, 4 cases.

YELLOW FEVER.

Rio de Janeiro, February 22 to 29, 298 cases, 199 deaths.

CHOLERA.

Calcutta, February 22 to 29, 71 deaths; March 1 to 7, 122 deaths.
Bombay, March 3 to 10, 4 deaths.
Alexandria, February 26 to March 4, 6 deaths.

CONSULATE-GENERAL OF THE UNITED STATES OF AMERICA,
RIO DE JANEIRO, March 3, 1896.
Dr. Walter Wyman, Supervising Surgeon-General, U. S. Marine Hospital Service, Washington, D. C.

Sir:—I have the honor to remit report for the week ended Feb. 29, 1896. There were 50 deaths from *accessio pernicioso*, an increase of 7; 199 from yellow fever, an increase of 4; 7 from smallpox, an increase of 1; 8 from beriberi, an increase of 4; 9 from enteric fever, a decrease of 2; 58 from tuberculosis, an increase of 4; and none from whooping cough, in the foregoing week. There were 643 deaths from all causes, the same as in the previous week.

Yellow Fever. There was an increase of only 4 in the number of deaths from this cause, but an increase of 80 in the number of cases reported, so that the disease is decidedly on the increase, though at this advanced stage of the season we may soon look for a favorable change. Although the temperature has been comparatively low, due to almost daily rains, we have had the increase above stated, which I can only attribute to the insane orgies of the carnival, which preceded the unfavorable change. The compact crowds, in all the principal streets, of individuals heavily clothed and masked, exposed to sun and rain, in numerous cases with uncovered heads, can only produce disease in the hottest season of the year, and during the reign of an epidemic disease in a tropical town. Indeed the authorities are well aware of this fact, and have tried to remove such a serious cause of deaths, but in vain, the populace will have the festa and that is all.

Smallpox. This disease is very slowly finishing, but it is unusual to have any but sporadic cases at this time of the year. The most ignorant classes avoid all sanitary rules as much as possible, hence the disease extends itself; only a few days ago a Portuguese who keeps a small and dirty restaurant for the laboring classes, nearly in front of my residence, was heavily fined and forced to remove, and his house thoroughly disinfected, because he had had a case of smallpox in a small, dark room adjoining the shop, hidden from the authorities, and from whom the contagion extended to others. I cite this case as one of many. Respectfully yours, R. CLEARY, M.D.,
Sanitary Inspector, M.-H. S.

SOCIETY NEWS.

The Association of American Medical Colleges.—The next regular meeting of the Association will be held at Hotel Aragon, Atlanta, Ga., May 4, 1896.

On invitation of the American Academy of Medicine, the Association will meet with that body to discuss several papers on medical education at 9 A.M. The regular official session will be held at 4 P.M., Monday, May 4, 1896.

The following program corresponding with the by-laws of the Association is proposed:

ORDER OF EXERCISES.

1. Reading of minutes of previous meeting by the Secretary. Adjournment of ten minutes.
2. (a) Roll call of membership. (b) President's Address. Prof. Wm. Osler.
3. (a) Report of committee on syllabus. Drs. Howard Kelly, Perry Millard, Bayard Holmes. (b) Report of committee on preliminary education. Dr. Fletcher Ingals, Chairman. (c) Reports of other committees. 1.) Relative to constitutional amendments. 2.) Relative to by-laws.
4. Financial report of Secretary-treasurer, Dr. Bayard Holmes.
5. Report of Judicial Council, Dr. Dudley S. Reynolds.
6. Reading of papers.

(The day of meeting of the Association was changed, at Baltimore in 1895, so that time might be given to the presentation of papers. Each paper will be limited to fifteen minutes. A syllabus must accompany the title and be in the hands of the Secretary not later than April 20. Only three papers can be read in full.)

7. New Business. (a) Constitution amendment relative to entrance requirement offered by the University of Colorado. Sec. 1, Article III. (b) Constitution amendment relative to Sec. 4, Article III. (c) Other amendments. (d) Other new business. (e) Election of officers. (f) Adjournment.

The University of Colorado proposes the following amendment to the Constitution, viz.:

"That Section 1, Article III, be amended to read, 'That the preliminary examination provided for shall be conducted by a Board of Examiners in no wise connected with a teaching body of a medical college.'"

Representatives of the Rush Medical College, the Woman's Medical School of the Northwestern University, and the College of Physicians and Surgeons, all of Chicago, propose the following amendment to the Constitution:

"That for the first paragraph of Section 4, Article III, the following be substituted:

"College members of this Association are free to honor credentials issued by colleges of equal requirements except in the case of branches embraced in the fourth year of their own curriculum."

This notice is sent to every regular medical college in the United States, and every college willing to conform to the requirements of the Association is requested to make application for membership and send a representative to the Atlanta meeting. Unless otherwise directed, the dean or president of a medical college will be considered its representative.

BAYARD HOLMES, Sec'y,
 Venetian Building, Chicago, Ill.

WM. OSLER, President, Baltimore.

NECROLOGY.

A. H. WILLIAMS, M.D., of Nashville, Tenn., April 10.—H. M. Fiske of San Francisco, Cal., April 3.—Robert Burnside, M.D., of Barboursville, Ky., April 2.—John I. Ellet of Kansas City, Mo., March 30, aged 85.—Dr. McCall, Wakenda, Mo., April 4.

DR. W. T. CARTER of Louisville, died on the 11th inst., at his residence of appendicitis. He was operated upon on the 6th and did well for two days but peritonitis developed and he died very soon after. Dr. Carter was born in Oldham County forty-seven years ago. He came to Louisville when quite young and deciding upon the study of medicine began his work at the Kentucky School of Medicine, from which he graduated in 1870. He has been connected with both the Kentucky and the Louisville Medical Colleges. He had a wide acquaintance and a large practice and his death is generally deplored. He leaves a wife and two children, one a daughter attending the Female High School, and the other a son who will graduate from the Louisville College of Dentistry in June. The funeral took place on the 12th inst., from his late residence, his remains being interred in Cave Hill, temporarily until they can be cremated, which was Dr. Carter's wish.

L. L. SASSER, M.D., of Smithfield, N. C., an alumnus of the University of Virginia of the class of 1883, and a sanitarian of more than local repute, is the subject of the following minute of respect in the State Board of Health's *Bulletin* for March, 1896: "It is with unfeigned regret that we chronicle the death of the late Superintendent of Health of Johnson County. Dr. Sasser was a gentleman of intelligence and education, well equipped for his profession, of pleasant address and deservedly popular. He will be greatly missed."

DR. JOSEPH A. MURPHY died on Easter Sunday at his home in Wilkes Barre, Pa., aged 54 years. He was one of the best known and most popular physicians in the Wyoming Valley, and was present at the Baltimore meeting last year. He was graduated in 1868 by the Medical Department of the University of Pennsylvania.

MISCELLANY.

Association of Life Insurance Medical Directors.—The annual meeting of this association will this year be held at Richmond, Va., on April 30 and May 1.

Prof. Behring's Gift to Science.—Our foreign exchanges announce that Behring has donated the 25,000 francs he received from the "Albert Levi" prize to establish a fund for sero-therapeutic research.

Concerning Exhibits, the following extract from by-laws of the Medical Society of the State of Pennsylvania is announced as governing the committee of arrangements of that society at the next annual meeting: "The committee of arrangements of each annual meeting shall grant the privilege of exhibition under the auspices of the society only to such pharmaceutical articles as are recognized by the United States Pharmacopeia, or are not protected by trade mark, secrecy of preparation or other exclusive proprietorship."

Female Physicians Wanted. The *Medical Examiner* says that the "New York State Civil Service Commission finds great difficulty in securing suitable candidates for the position of women physicians in the State Hospitals. These positions are desirable ones, paying from \$1,000 to \$1,500 per year, beside giving ample opportunity for practice and study in nervous and mental diseases, with pleasant home and associations. The examination advertised in January failed for lack of applicants. Application for this examination should be made to the Secretary of the State Commission, at Albany."

Sound Health in Insurance Law.—The appellate division of the supreme court of New York says, in its decision of *Robinson v. Metropolitan Life Insurance Co.*, Feb. 4, 1896, that the term "sound health" is capable of different meanings. An idiot may be in sound health physically, and the same is also true of a cripple. For this reason, it holds that if the defendant insurance company, at the time it issued the policy, was apprised of the actual condition of the insured, that she was an idiot and a cripple, the term "sound health" should be construed as referring only to her physical condition, apart from her mental imbecility or the fact that she was crippled, and a provision in the policy that no obligation was assumed by the defendant unless, at its date, the insured was alive and in sound health, did not void the policy.

Power to Remove Superintendent of Hospital.—The grant of power to appoint to public office, as for example to the office of superintendent of a State hospital for the insane where no term of office is fixed by law, the supreme court of North Dakota holds, in the case of *State v. Archibald*, decided Feb. 20, 1896, carries with it as an incident the absolute power of removal at any time, without notice or charges or a hearing, and without the cause for removal being inquired into by any court. Such power vested in a board can not be limited by any action taken by such board, whether by appointing the officer for a fixed term, or by by-laws restricting the power of removal to cases where cause for removal exists. The people, under such legislation, have a right to demand that whenever the board shall deem it for the public interests to remove the officer, its power of removal shall be the absolute power vested in it by the legislature, and shall not be fettered by any restriction whatever. *Mandamus* is the proper remedy to compel one who has no color of title to an office to surrender it to one who holds the *prima facie* title to it.

Duty of Telephone Companies.—A decision of interest to physicians and those who have occasion to call them by telephone is that of the appellate court of Indiana in the case of *Central Union Telephone Co. v. Swoveland*, rendered Feb. 12, 1896. It holds that it is the duty of a telephone company doing a toll service to send out a messenger from the receiving station and notify the person called for that he is wanted at the telephone, unless the distance is one such that it would be unreasonable to require it, and that the company is responsible for the acts and omissions of the messenger whom it employs, notwithstanding it has rules and regulations declaring him to be the agent of the person desiring to be placed in communication with the one called for. In this instance it was a veterinary surgeon who was wanted, and the court further holds that in computing the amount of damages recoverable by the owner of a fine horse on account of several hours being lost by the surgeon in reaching him through the negligence of the telephone company, that the value of the horse could not be taken into consideration because it was mere speculation whether the life of the horse would have been saved had the messenger delivered the call at once.

Rules as to Expert Testimony. Where a person has been educated as a physician and surgeon, the court of appeals of Kansas holds, in the case of *City of Wichita v. Coggs*, decided Feb. 6, 1896, he may give his opinion on questions pertaining to his profession, and may testify from his personal examination. When he does so his opinion must be derived from his examination, and not dependent upon the statements of others. If he does not speak from his personal examination, his opinions must be based on hypothetical questions propounded to him; the hypothesis must be based on the truth of all the evidence given in the case, and must be so framed that he can answer it intelligently; and his answer must be based on the hypothesis stated, and not from a consideration of what might or might not happen under certain conditions; it should be an

opinion of the witness predicated on the hypothesis containing the facts. Where a witness, in his answer to a hypothetical question, makes answer that is not responsive to the question, and states facts that are incompetent as evidence, the court should strike the answer out, and direct the jury not to consider it as any part of the evidence in the case.

A Special Patent Medicine Tax. Among the laws passed in Missouri in 1895 was one providing for the endowment of the State University, and for the establishment and endowment of free scholarships therein, the third section of which provides that every manufacturer of medicines or remedies commonly known as patent medicines shall pay a license tax of \$25, and every traveling vender of such medicines or remedies shall pay a license as now provided by law; and every such traveling vender shall take out a license in every county in which he vends such articles. Every manufacturer or traveling vender failing to pay the license tax provided by this section shall be guilty of a misdemeanor, and upon conviction be punished by a fine not to exceed \$100. The city of St. Louis is to be treated for the purposes of this act as if it were a county. The taxes or fees and fines are to be appropriated for the purposes of the act.

The Inventor of the Ophthalmoscope. Prof. T. C. Mendenhall, in a recent eulogium on the late lamented Helmholtz, refers to his beneficent contributions to ophthalmology, especially the working out of the ophthalmoscope, as having opened a new page in the history of medical optics. He refers to the rare combinations of expert knowledge in the intellect of Helmholtz tending to make possible the rich scientific contributions made to the world, but particularly to the fact that Helmholtz was at once an accomplished physiologist, mathematician and physicist. He says: "It was in 1851 that the Professor made known his invention of the ophthalmoscope, and a few years later that of the ophthalmometer that bears his name. Anxious to actually see what goes on in the eye, and especially on the retina, that wonderful screen on which the image of the visible world is focused, he invented the ophthalmoscope. The qualitative victory was followed by the quantitative, in the invention of the ophthalmometer, by means of which accurate measurements of the various curved surfaces in the eye could be made. These two instruments have been to ophthalmic surgery what the telescope and graduated circle have been to astronomy. So exact has the science of the eye become through their use that it is not great exaggeration to say that one may now have disordered eye repaired, corrected and set going with little more uncertainty than attends the performance of the same duty for an ill-conditioned chronometer. Had Helmholtz accomplished nothing except the invention of these instruments he would have been entitled to the thanks of all mankind, on account of the comfort they have added to life and the pain and suffering they have prevented."

Expert Testimony on Delusions, Illusions and Alcoholic Delirium.—Dr. Austin Flint, of New York city, recently testified in an important will case, on trial at Hartford, Conn. He is reported to have said, when speaking of the effects of alcoholic liquor taken to excess, that in the first instance, it "interferes with the digestion and appetite. Such persons are likely to have a development of flabby fat. They are likely to have cirrhosis of the liver, trouble in the kidneys and in the nervous system. As a rule the trouble begins at the ends of the nervous system. It may lead to disturbances in motion, owing to the effect on the brain. The immediate effect of alcohol is that the person may do extravagant things. He may be brilliant and witty; others stupid; others lachrymose. It is very rare that an ordinary drunk terminates in delirium tremens. He would place the line of demarcation between an ordinary drunk and the drunk that terminates in delirium tremens at the time when a person becomes markedly delirious and has illusions that

develop into hallucinations, and when he begins to see small objects, as flies, first, and gradually begins to see snakes and devils. A hallucination is consistent with a sound mind: an illusion is a faulty perception of sight, hearing or other sense. A delusion is false reasoning, believing something that has no logical existence. There is a distinction between a delusion and an insane delusion. A delusion may be consistent with a sound mental condition. An insane delusion is a false reasoning of which it is impossible to disabuse the mind. With very few qualifications, there is no such thing as insanity without delusions. A patient suffering from delirium tremens usually recovers in a few days and goes back to his normal condition. When alcoholic persons become insane there are pains in the extremities of the nerves and the speech becomes slow. So long as no delusion existed the person could not be considered insane.

Hermetic Sealing not Indispensable.—Objection was made in the case of *State v. Thompson*, decided by the supreme court of Missouri Feb. 4, 1896, to certain testimony relating to the chemic analysis of some cheese and the contents of a jar containing the stomach, kidneys, etc., of the deceased, based solely upon the proposition that the jar in which the physician who made the post-mortem placed the stomach, kidneys, etc., was not hermetically sealed. Wharton and Stille's Medical Jurisprudence was cited as authority for this; but the court says that the text does not support the contention. It needs no argument or authority, says the court, to establish that the burden is upon the party relying upon a chemic analysis to detect poison to satisfy the court and jury of the identity of the body examined with that which he asserts was poisoned. This fact, like any other, must depend upon the precautions taken. Certainly, the court continues, the physician making the post-mortem can not be too careful in seeing that the parts he desires analyzed should be carefully separated to themselves, and so kept as to silence any suspicion or doubt; but it may often happen that the proof is entirely satisfactory that the part or parts reserved for the analysis have never been tampered with by anyone whose interest might lead him to destroy or alter them, and, though not hermetically sealed, the analysis would not for this reason be rejected. In this case, there being no evidence to create a suspicion that the parts received by the analyst for his analysis were other than those preserved by the physician who made the post-mortem, the court holds that the analyst's testimony was not rendered inadmissible because the jar in question was not hermetically sealed.

Insane Prisoners to be Transferred to Asylums.—In Indiana a law was passed in 1895 requiring the wardens of the State prisons to report all cases of insanity that may occur in such prisons to the Governor of the State. The latter shall then order the warden to convene a lunacy commission to be composed of prison physician, one resident physician and two justices of the peace, of the township in which the prison is located, whose duty it shall be to investigate and examine into the mental condition of the person alleged to be insane, and report in detail, in writing, to the warden who shall transmit the report to the governor. Upon receipt of the report it shall be the duty of the governor to determine if the person shall be transferred to an insane asylum, and if so, to what asylum, and the conditions upon which the transfer shall be made. The governor may pardon the person and order the transfer made. He may parole the person and order the transfer made. He may order the person transferred to the insane asylum to be returned to the prison when cured of the mental disease to serve out the residue of his term: provided that such person shall have the benefit of the time spent in the insane asylum: and provided further, that if not reported cured of his mental disease by the time his sentence would have expired in prison, he shall be dis-

charged from the prison rolls, and that fact shall be reported by the warden to the superintendent of the insane hospital. It shall be the duty of the superintendent of the insane asylum in all cases where the person is cured of his mental disease, prior to the expiration of his prison term, to report that fact to the governor, who shall then order the warden of the prison from which he was transferred to proceed to the asylum and return the person to the prison, there to serve the residue of his term. In all other cases the person shall be subject to dismissal in compliance with the laws governing the dismissal of persons from insane asylums.

Practical Notes.

Guaiacol Anesthetic Injections.—The European Edition of the *Herald* states that the *Figaro* has a despatch from Dr. Pize of Montelimar that he has discovered that by injecting guaiacol under the skin in small doses, operations can be performed without pain. The committee of the Academy of Medicine appointed to inquire into the value of this discovery has sent its congratulations to Dr. Pize.

Diagnostic Importance of Uric Acid and the Xanthin Bases in the Urine.—Brandenburg reports in the *Berl. klin. Wochenschr.*, 6-8, the results of the study of a number of wasting diseases to determine the effect of extensive karyolysis on the nitrogenous substances in the urine. He found that diminished nutrition as well as pernicious anemia and mild gastric troubles were accompanied by a diminished elimination of nitrogen in the urine, and also by a diminished amount of alloxanthin substances. In acute infective diseases like scarlet fever, typhoid, etc., the amount of nitrogen and xanthin nitrogen was increased, corresponding to the increased amount of destruction of the albumin of the body. Most interesting was the investigation of these substances in the cachexia accompanying carcinoma. The total of nitrogen was exceedingly small, while the amount of alloxanthin substances was exceedingly large. Brandenburg is inclined to think that this fact may be found valuable in diagnosing carcinoma.—*Wien. klin. Rundschau*, March 8.

A New Method of Estimating Albumin in Urine.—According to the *British Medical Journal*, Riegler of Vienna has brought forward a new and rapid method of estimating albumin by means of the refractometer. It depends upon the power of his new reagent, asaprol, to precipitate all albuminous substances in acid solution: the precipitate is soluble in weak caustic soda or potash, and the refractive index of the solution bears a direct relation to the amount of albumin present. In practice the asaprol (10 per cent.) is made up with 10 per cent. hydrochloric acid. Exactly 25 c.c. of decinormal potash solution are used, and added to the precipitate resulting from the mixture of 5 c.c. of asaprol solution with 50 c.c. of urine. The refractive indices of the resulting fluid (after filtration) and of the potash solution are determined by Pulfrich's refractometer, and their difference divided by 270 gives the exact percentage of albumin present. The coefficient 270 was determined by Riegler as the result of experiments on measured quantities of albumin.

Diagnostic Value of Tuberculin.—Grasset and Vidal have been studying this subject and announce that tuberculin has been administered in too large doses for this purpose, hitherto. They made subcutaneous injections of 5-10 milligram after patient had been kept in bed three days. The reaction is sometimes tardy in appearing, or very feeble, and it must be borne in mind that leprosy, actinomycosis and syphilis also react, so that the test is only certain in the absence of these troubles. But it discloses tuberculosis in cases impossible to diagnose in any other way. In the case of animals, the committee appointed to report on tuberculin stated that it is a very valuable means to detect tuberculosis in cattle, and they warmly recommended its use. All the animals are inoculated and those who react are separated from the rest, and the barns disinfected. Thirty to fifty

centigrams will raise the temperature from one and a half to two and a half degrees C. The test requires twelve to fourteen hours.—*Bulletin de l'Académie de Médecine*, February 25.

The Six Groups of Antithermic Analgesics.—The *British Medical Journal* gives a review, chiefly clinical, of these remedies. They may be classed as follows: 1. Phenol group, with phenic acid as its chief. The chief action of these is antiseptic; their analgesic powers are feeble. The objections are that they are protoplasmic poisons, they paralyze or destroy the blood corpuscles and depress or paralyze the nervous system. Their antithermic action is energetic but transitory. More permanent reduction of temperature can be obtained only at the risk of dangerously toxic doses, or at that of inducing cachexia and profound anemia by frequently repeated small doses. 2. The aromatic acid group, chief of which is salicylic acid. The chief characteristic is a still predominant antiseptic action, less toxicity than group 1, owing to the substitution of COOH for OH. Apart from rheumatism their analgesic power is weak. The large doses required to lower temperature cause digestive troubles, buzzings in the ears, and even cardiac enfeeblement and renal irritation. But with undamaged kidneys they increase diuresis and depurate the blood of extractives and nutritive residue. 3. The anilid group. Its antiseptic properties, though strong, are less than those of phenol and salicylic acid. The fall of temperature caused is rapid, but transitory, with abundant sweats, shiverings, cyanosis, and often hemoglobinuria. 4. The phenylhydrazin group, which are even less satisfactory than the anilids. Like the latter, they are eliminated as amidophenol derivatives. 5. The chinolin group possess considerable antifebrile and antiseptic properties, but are liable to disorder the digestive tract and to give rise to severe nervous symptoms. Their antithermic power is fugacious, attended by profuse sweating, collapse, etc., and attended by too severe corpuscular destruction. Hence, as a group, they are not satisfactory. 6. Pyrrol group, the most important and almost the sole representative of which is antipyrin. Endued with a real antifermentative and microbicidal action, almost inoffensive as regards the blood, it possesses antithermic and analgesic properties second to none. A few derivatives of antipyrin must be mentioned, salipyrin, tolpyrin, tolalsal, which do not present any special advantages.

Philadelphia.

A CORRECTION.—The preparation of iron used by Prof. Da Costa for hypodermic use in anemia, is the citrate of iron and manganese (not *magnesia* as given on page 747 of last week's issue). It makes a clear and permanent solution with distilled water, in the strength of three grains of the salt to fifteen minims of water, which is the usual dose, given once daily.

JEFFERSON MEDICAL COLLEGE.—The property adjoining the College on Tenth Street, extending south from Medical Street to Walnut Street, has just been purchased by the trustees, it being the design to erect a modern structure adapted to laboratory and clinical teaching, on the corner of Tenth and Walnut. This will afford facilities for the large classes at Jefferson, the need of which becomes greater every year. The Alumni Association is actively engaged in collecting the funds to fit up the new laboratory.

Louisville.

CLINICAL SOCIETY.—Dr. Aug. Schachner entertained the Clinical Society on the 7th inst., the subject of his essay being "Transfusion, Infusion and Autofusion."

DR. SIMON FLEXNER, Fellow in Pathology at the Johns Hopkins Hospital, delivered an entertaining and well prepared lecture, under the auspices of the Louisville Female High School Alumni, on the 6th inst., at the Female High School. Its title was "Infectious Diseases in the Light of Modern Investigation," and was a learned discussion of the subject, though a little too scientific for the audience which listened to him. The

lecture was well illustrated by specially prepared charts which added much to the interest.

M. H. GWINN, who was indicted at the December term of the circuit court of Bardstown for empiricism, has been convicted of false swearing and practicing with a license and sentenced to two years in the penitentiary. He is under indictment by the circuit court, of Lawrenceburg, and will be tried there upon the expiration of his term in the prison. This ends rather a famous case, the defendant in the case having been convicted and fined on several occasions for practicing without a license. He is uneducated and illiterate, his great claim being that he could cure typhoid fever in a week. Not having a diploma and no license, an opportunity was given him to appear before the State Board of Health and undergo the examination which was held under the new law. He refused to take the examination if he had to tell his treatment for typhoid fever, was finally persuaded to try it by his attorney, and the papers which he handed in and upon which a license was refused him by the board are marvels, although he did not say anything about his typhoid fever treatment. It is a great source of gratification to the members of the State Board that he has at last met with his just deserts.

HEALTH OFFICER'S REPORT.—The report for the past week shows a total number of deaths of 69. Consumption heads the list with 16 deaths; 8 were caused by pneumonia. There were 6 stillbirths. There were 2 diphtheria cases placarded and 5 cases of scarlet fever.

Detroit.

THE DETROIT MEDICAL and Library Association at its regular meeting Monday, April 6, had a paper by Dr. George Thomas Jackson, of New York, entitled "Too Much and too Little Hair." The paper brought forth discussions from Drs. A. E. Carrier and Andrew P. Biddle. Dr. Carrier said that he could remove from thirty to sixty hairs at a sitting, but not more, and that he found that the upper lip was the most difficult part of the face to remove superfluous hair from, on account of the pain: that he was in the habit of telling patients that about 30 per cent. of the hairs would return, so as to protect himself and not cause too much disappointment to patients. Had not had much trouble with scars after the electrolysis. He had ladies consult him for the removal of hairs from other parts of the body as well as from the face, and said that it was not always the masculine female who was the one who was troubled, and cited a case of a woman with quite a growth not only upon the face, but upon the chest and other parts of the body. The Doctor thought that loss of hair in early age was always due to seborrhea, and when applying medicines to the hair, he instructed his patients to part the hair and use a tooth brush, as in this manner it could be done systematically and thoroughly. Frequent washing and wetting the hair was another cause of alopecia. He also said that he was in the habit of using resorcin in a lotion as an application to the hair and head. The prognosis is unfavorable, as the alopecia will return. The Doctor related the case of a lady who was quite bald and under treatment. Some of the hair bulbs responded with the result that she had some hair, but it was thin and long. Dr. Andrew P. Biddle said that he thought heredity played an important part in this trouble, and related a case where the grandfather, father and son had no hair upon face or other parts of the body, and where the brother of the youngest patient had an undescended testicle. The Doctor thought that there was some relation between the genital system and the hairy portions of the body. He said that he was not able to remove the number of hairs that the essayist had said he removed at a sitting. Dr. Biddle gave his reasons why women were not bald, as a rule. The condition of the scalp, he said, was thicker than in man, which allowed a greater number of blood vessels and a greater number of sebaceous glands: the scalp being thicker was more movable. In applying medicine, the Doctor

did not think that it was always the medicine that did the good, but rather the systematic manner in which it was applied; that, in other words, it was the massage from which the benefit arose, and not the stimulating effect of the medicine always. Dr. Jackson, in replying, said that in a sitting of forty-five minutes he expected to remove about sixty hairs, and that he differed with Dr. Carrier as to the upper lip being a particularly difficult place about the face from which to remove hairs; that he himself had found it quite easy to remove the hairs from this locality, on account of the straight direction of the bulbs. He told his patients that from 15 to 20 per cent. of the hairs would return, but with electrolysis all hairs could be removed, also small tumors, moles, etc. The Doctor also spoke of the calcium hydrosulphid for the removal of small hairs (lanugo), especially for surgical purposes.

THE WAYNE COUNTY MEDICAL SOCIETY, at its meeting April 9, listened to a paper by Dr. Wm. R. Scurr, entitled "Yellow Atrophy of the Liver." In his paper the Doctor reported a case that he had had some two months ago, in which all the symptoms of this disease were present, and by which he made his diagnosis, as no post-mortem was made.

WEEKLY HEALTH REPORT for week ending April 11. The weekly report at the Health Office shows that there were 96 deaths the preceding week, of which 35 were children under 5 years of age. At present there are 7 cases of diphtheria and 25 cases of scarlet fever. Three deaths were caused by diphtheria. During the week 88 births were recorded, of which 47 were males.

Washington.

WEEKLY REPORT OF THE HEALTH DEPARTMENT.—The report of the Health Officer for the week ended April 4 is as follows: Number of death (stillbirths not included), 98; death rate per 1,000 per annum, 18.50; death rate per 1,000 per annum corresponding week last year, 17.33.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—The 244th meeting of the Society was held on the 3d inst. Dr. W. W. Sprigg reported a case of pregnancy complicated with intestinal obstruction followed by accidental hemorrhage and miscarriage. Dr. F. S. Nash reported a case of post-partum mania.

MEDICAL SOCIETY.—At the meeting of the Society held on the 8th inst., Dr. Clark read a paper on infantile paralysis. Dr. Lamb reported a case of rupture of the aorta and presented the specimen.

ANNUAL MEETING OF THE MEDICAL ASSOCIATION.—At the regular meeting of the Medical Association of the District held on the 7th inst., the following officers for the ensuing year were elected: President, Dr. W. P. Carr; Vice-Presidents, Drs. Hawkes and Scott; Secretary, Dr. J. R. Wellington; Treasurer, Dr. H. M. Deetle; Counsellors, Drs. Crook, McLain, Ober, Holden, Acker, Kober, T. R. Stone, Yarnell, and D. O. Leech; Censors, Drs. Woodward, Ruffin and Mayfield; delegates to the meeting of the American Medical Association to be held in Atlanta, Ga., May 5, 6, 7, and 8, 1896, Drs. J. T. Johnson, Kleinschmidt, Belt, Sothoron, Heiberger, Franzoni, L. Eliot Rich, Woodward, Nordhoff, I. S. Stone, S. Muncester, Magruder, Acker, Kober, Bowen, Nash, Scott, Wellington, C. G. Stone, Cook, Fry, E. L. Morgan, W. W. Johnston, Van Rensselaer, Busey, F. Leech, J. F. Thompson, S. S. Adams, Lincoln, Hunt, McLaughlin, J. D. Morgan, Mayfield, Peter, Suter and Carr.

GARBAGE REGULATIONS: VIOLATIONS. The police regulations of the city require that every premise from which garbage is to be collected shall be provided with water tight receptacles, not smaller than three gallons nor larger than ten gallons, to be provided with a tight-fitting cover. Disregard of these regulations is punishable by a fine of from \$5 to \$10. The law is not generally observed by householders and a number of cases of violation are soon to be punished.

THE VENTILATION OF THE HOUSE.—The House Committee on Ventilation and Acoustics has devoted another session to the examination of experts concerning a proposed new scheme for the better ventilation of the House wing of the Capitol building. The committee has about come to the conclusion that the downward system of ventilation is preferable to the one now in vogue, viz. the upward system, and a bill providing for a change may be reported. The estimated expense necessary to make the change is \$100,000.

CENTRAL DISPENSARY AND EMERGENCY HOSPITAL.—At the regular monthly meeting of the Board of Directors of the Hospital the following report of its staff for the past month was received: Number of new patients, 843, number of visits 3,396, operations 121, prescriptions 4,318, ambulance calls 32, emergency cases 182, redressings 280, ward patients 41. Drs. Blanche Greaves and Ella M. S. Marble were appointed assistants on the service of Dr. H. L. E. Johnson.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 4 to 10, 1896.

Capt. Paul Shillock, Asst. Surgeon (Madison Bks. N. Y.), is granted leave of absence for four months, to take effect on or about May 1, 1896.

Capt. Ashton B. Heyl, Asst. Surgeon U. S. A. (Ft. Thomas, Ky.), is hereby granted leave of absence for one month, to take effect on or about April 20, 1896.

First Lieut. George J. Newgarden, Asst. Surgeon, will be relieved from duty at Fort Wayne, Mich., and ordered to Ft. Yates, N. Dak., for duty at that post.

Capt. Benjamin Munday, Asst. Surgeon, is relieved from duty at Ft. Niobrara, Neb., to take effect upon the expiration of his present sick leave, and ordered to Fort Wayne, Mich., for duty at that post.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending April 11, 1896.

P. A. Surgeon L. L. Young, detached from the naval hospital, Norfolk, and ordered to the "Albatross."

P. A. Surgeon E. S. Bogert, detached from the "Albatross," ordered home and granted three months' leave.

Asst. Surgeon J. M. Moore, detached from the "Vermont" and ordered to the naval hospital, Norfolk.

Change of Address.

Brener, Chas. H., from 1726 So. 9th St. to 1411 So. 13th St., Omaha, Neb.

Blakely, T. J., from St. Louis to Avalon, Mo.

Coppage, W. E., from St. Louis to Oak Hill, Mo.

Farnum, C. E., 703 Market St. to 661 Market St., San Francisco, Cal.

Green, T. S., from 61st and Halsted St. to 39th and Cottage Grove Ave., Chicago, Ill.

Gunn, Janet, from 618 W. Monroe St. to 5127 Cornell Ave., Chicago, Ill.

Gudex, V. A., from 793 3d St. to 819 3d St., Milwaukee, Wis.

Hamblin, J. M., from Chicago, Ill. to Westboro, Mo.

King, F. R., from Anita to Wiota, Iowa.

Lincoln, D. T., from 73 Pluckney St. to care of C. J. Blake, 226 Marlborough St., Boston, Mass.

Malone, L. A., Jacksonville, Ill. to 427 Senate Ave., N. Indianapolis, Ind.

McKown, T. D., from Chickamauga, Ga. to Cripple Creek, Colo.

Smith, S. L., from 610 W. North Ave. to 350 Webster Ave., Chicago, Ill.

Van Hook, Weller, from 858 W. Monroe St. to 4043 Grand Boul., Chicago, Ill.

ADDRESS.

MEDICAL PROGRESS, ITS HELPS AND HINDRANCES.

Delivered before the Sixty-third Annual Session of the Tennessee State Medical Society, at Chattanooga, April 14, 1896.

BY G. C. SAVAGE, M.D.

PRESIDENT OF TENNESSEE STATE MEDICAL SOCIETY.
NASHVILLE, TENN.

Medicine, like all other things terrestrial, had its beginning. When disease entered the world, medicine must have been born to meet it. Who first concocted a cooling draught to quench a fevered thirst must forever remain unknown. What the first surgical operation, and by whom performed, is likewise shrouded by the impenetrable gloom of the past. While I would not rob Hippocrates of the honor of being the father of medicine, in that he probably was first to reduce it to a science, nevertheless the generations who preceded him must have been blessed with men skilled to heal in that they must have been cursed by disease. The depth and extent of their knowledge, measured by the aids they had, must have been little; their skill to use the crude means for cure, at their command, could not have surpassed their knowledge of disease. It may be that anciently inspiration more than investigation made men strong in ability to cure. This generation may learn lessons in hygiene from inspired Moses, who lived and taught before Hygieia was deified.

But it is not my purpose to trace the progress of medicine from its small beginning, in the very remote past, to its present proud position among the great sciences and arts. It is yet an unfinished science, and as an art still imperfect, notwithstanding our multitude of remedies and our surgical appliances by the thousands. Medicine progressed, hindered as she was through many centuries by ignorance and superstition, her chiefest enemies. Within the present century the greatest progress has been made. That the march of medicine will go on until she shall stand a perfected science, I can believe, though this end may not be attained for many centuries to come.

I believe that the time is coming when the world will be redeemed from ignorance, degradation and disease. Teachers, preachers, lawyers and doctors will all have much to do in ushering in the millennium.

The reason medicine has advanced most within the century now about to close, is that she has had fewer hindrances and more helps. Superstition, which was an incubus on the chariot of progress in past centuries, dwindled almost to naught before the present century dawned. Ignorance, the mother of superstition, failing in her power to fully nourish her offspring, began to pass into her decline, her power to prevent progress greatly lessened. While the darkness of ignorance and superstition has not entirely disappeared, it has been rendered less potent for harm

because of the accumulated light of knowledge with which the world is now flooded.

The conditions which hindered progress in the past, if existing, could hinder now. Unfortunately, some of them do exist, and it is equally certain that they have their retarding influence.

HINDRANCES.

Bigotry, whether characterizing an individual or a class of individuals, in matters medical never had other than a harmful effect. It would be well if this ill-shaped monster could be forever buried, without hope of resurrection. Men who are not willing to accept facts presented by others, and will not weigh the conclusions that have been based upon them, are not the men who will make advances themselves, nor will they be helpful to others who would. Destroy bigotry and there will be no "pathies," but in their stead would stand one grand brotherhood of physicians. A medical bigot knows not enough to know that he does not know it all, and therefore always stands ready to destroy anything that does not emanate from a source peculiarly his own. Such an one would say, "I will not use this instrument because it was invented by a homeopath; I will not administer that drug because it was introduced by an eclectic; I will not bathe my fevered patients nor give them cooling draughts because this is the method of the hydropath; I will not listen to suggestions coming from common people." The man who would attain to the greatest wisdom must gather grains of thought from all fields, must use his judgment in separating the good from the bad, and must be willing to feed his fellow men from his well-filled granary. If Jenner had not listened to the stories of the milkmaids, vaccination would not have been discovered, and the era of immunization, inaugurated by Pasteur, but founded on Jenner's discovery, would have been longer delayed. We should not forget that all people are God's people, and that He may use one or another in bringing into the world the good which comes alone from Him. Away with bigotry and send bigots with it!

Jealousy, although a personal property, can do a general harm. It is always a sign of weakness and is usually directed against one who is stronger, or gives promise of becoming so. Medical jealousy is a medical cur that rarely faces the one whom he would frighten, but watches for his opportunity to slip up from behind, and always with more bark than bite. A timid though talented man, just entering the field of investigation, may become so frightened by the bark of jealousy as to flee the field and forever fear to enter it again. Thus to the world may be lost results that otherwise would have followed. The medical man who is afraid of jealousy deserves pity: the jealous man merits only contempt.

Laziness, an inherited tired feeling, afflicts some men to such an extent that they neither accomplish anything themselves nor do they help others who would

do something. This is a sort of passive hindrance to progress, and is harmful chiefly when it engages in idle conversation one who would be better employed. Of all professions and callings, the lazy man is least at home in medicine.

Carelessness, in more ways than one, may be the means of preventing progress. A careless reader can not get all that may be in the printed page: a careless observer can not properly interpret symptoms, and therefore may miss the mark in prescribing remedies. A careless man may have thoughts but he does not note them and they fly away, like a beautiful bird, to return his way no more. Such a thought noted within the pages of a little book, recalled at a more leisure time by a glance of the eye, and amplified by the reasoning powers, might bring strength to the person and progress to the profession.

Indifference about medical matters and medical men is not calculated to give speed to the car of progress. One thus affected may answer promptly all calls from the sick and may relieve them from their sufferings. Every page he reads may bring him profit; every patient may be an open book from whose leaves he gathers useful lessons. He is content with these two sources of information and what he gets he appropriates to his individual and exclusive use. He counts himself wise without knowing that he is foolish. He is of few words and therefore appears to be full of wisdom. He meets not with his brethren in medical societies for mutual improvement. His own thoughts he hoards as a miser does his gold. He is conscious of his strength but he is only too careful not to impart it to others, either by word of mouth or in the printed page. When he dies the good he has done is buried with him.

Exclusive medical organizations are not promotive of progress in the fullest sense. In a science so broad and with aims so high, narrowness in organization is an abnormality. The few who compose such a society may be the salt of the earth, but their savor is not so likely to be of service as if it were not thus enclosed. A holier-than-thou air emanates from a room containing such a coterie, and that is calculated to cripple the influence of the organization. To be *one of one hundred* has in it more sound than sense, and to be proud of such a distinction is more likely to hinder than he is to help the general progress. Such organizations tend toward becoming mutual admiration societies, and the members sometimes may imagine that the great body of physicians on the outside look upon them with admiration and awe. An exclusive organization with a national name is a travesty. It would be far better to say the "*best one hundred*" or "*the one hundred*," which would be a more modest way of putting it.

Vanity in a medical man is not usually well-founded and often is unregulated. Such a vanity always harms the possessor and is continually in the way of both personal and general progress. Competition is hateful to such an one, and without competition there can be no progress. If a man, by chance, has one thing that might excite his vanity, he doubtless has something else that should humiliate him. The peacock is proud of his feathers as he spreads them in the sunshine, but is humbled when he sees his feet; yet his feet are more useful to him than his gaudy tail. But prudent, well-governed vanity is a good thing, for with it competition is wedded and the legitimate offspring of this union is progress.

Common prejudice of all times and *laws* of some civilized countries have been hindrances. Dissection, vivisection and experimentation, against which the multitude are prejudiced, are as essential to advance in medical knowledge and skill as light, heat and moisture are to the growth of vegetation. If there is any excuse for medical men in politics it lies in the line of their preventing the enactment of laws that would lock the wheels of medical progress. At this moment the Congress of these United States is being urged by some who think more of the lower animals than they do of mankind, to enact laws against vivisection in the District of Columbia. If they are successful in this, they will conclude that it is just as wrong to cut up a dead man as it is to cut on a live rabbit, and they will ask for laws against dissection. It would be but one step further for them to ask for the enactment of laws against administering medicines to the poor in hospitals, whose virtues had not already been proved on millionaires. Thus encouraged they would leave Congress and go into our State legislatures and plead for the enactment of similar laws. If such laws should ever find their way into our statutes a strict enforcement of them would put an end to medical progress in this country. Let us hope that the men who make the laws for us will not be so barren of brains.

The public (not all the public), of whom *preachers* (not all the preachers) form a part, may be the means of hampering medical progress by encouraging quackery, using vile nostrums, and endorsing quack appliances which bear high-sounding names. Serious ailments lead people to think only of men skilled in healing; slight ills, or imaginary afflictions, afford the opportunity to quacks and nostrum dealers to deceive the people, and while under the pall of this deceit they forthwith "certify." If there is a man whom the people deify it is the family physician, and yet they degrade him when they buy a bottled nostrum, visit a quack for free consultation, or wear about them a device that has more name and price than power to do good. Let the people frown on quackery and refuse to buy, then quacks will vanish and the nostrum trade will die.

HELPS.

Some of the specific aids to the medical advancement of the century now about to close may be mentioned:

Anesthesia, local and general, has been given us, making painless surgery not only a possibility but a reality. While the hint for painless surgery was given more than six thousand years ago, when "the Lord God caused a deep sleep to fall upon Adam, and he slept," while the rib was taken from his side, it will always be a matter of pride to physicians of the South that Long, of Georgia, in 1842, was the first man to produce general anesthesia, and to do a painless surgical operation on sensitive human structure. It will likewise always be a matter of regret, on our part, that his modest nature and retiring disposition prevented his making public, except to a few medical friends, his great discovery, until, after a lapse of four years, Morton, of Massachusetts, announced his independent discovery of anesthesia. It will always be our pride as American medical men, to proclaim that our country gave anesthesia to the world. Without this boon surgery would have continued painful, and the great progress which has since been made would have been impossible.

Koeler, not then an American citizen, gave us cocaine as a local anesthetic, in 1884. In paying homage to him now, in recognition of the good he has conferred by his discovery, we honor an American citizen, for he resides in Greater New York.

Antisepsis, the introduction of Lister, and its legitimate outgrowth, *asepsis*, have so lessened the former disastrous results of surgery that the surgeon has been made bold in his operative work. Because of these gains untold suffering has been relieved; and, in innumerable instances, life has been prolonged. The greatest progress that surgery has ever known has been made within the last half of the nineteenth century, and the two factors that have had the most to do with this progress are anesthesia and asepsis. A closer study of pathology and symptomatology have aided greatly in the march of surgery.

Electricity, once known only by its riding the storm, leaping from cloud to cloud, and occasionally sending its shivering lance to the earth through some giant oak, a thing of superstition and dread, has been tamed to serve the well and heal the diseased. When Franklin tapped the cloud with his kite and brought the fiery fluid in a gentle stream down the slender cord to the key in his hand, he dreamed not that, in the nineteenth century, it would be made to light our streets and drive our cars. When Galvani saw the muscles of the dead frog contract and relax under the influence of this subtle agent, he had no thought to what uses it would be put by medicine and surgery ere the dawn of the twentieth century. When Crookes invented his tube only a few years ago, he did not foresee that, by means of it, Roentgen would be able to make shadow-graphs of things hidden from the light of day. Electricity is to-day one of the invisible forces giving speed and effectiveness to the progress of medicine.

Specialism had its birth in modern times, and has been a most important factor in the advance that our science and art have made. Neurology became a possibility with Wilson's study of the brain in the seventeenth century; but she did not grow to her present beautiful proportions until men of the nineteenth century devoted their time and talents to perfecting the work begun so long ago. McDowell's boldness in opening the abdomen of his Kentucky patient, led men to a more careful study of the pelvic and abdominal organs, and made gynecology and abdominal surgery a possibility. Who does not admire the men in this specialty for their boldness in operative procedure and their daring in the coinage of terms.

Helmholtz's invention of the ophthalmoscope, in 1851, created modern ophthalmology, and gave to medicine one of its most useful branches. It bears to-day the proud distinction of being more nearly founded on a purely scientific basis, than any other department of medicine. Proud of her progress and position, she is humiliated only by the fact that gynecology, her younger sister, has far surpassed her in adding long and high-sounding names to the medical vocabulary. Other specialties might be mentioned that have done much in advancing medicine.

The Drug Supply of this century, has had much to do with therapeutic progress. The mineral and vegetable kingdoms have been free in their gifts of remedies for human ills. Coal taken from the bosom of the earth has yielded her products for easing pain and reducing temperature. The cinchona tree wrapped in her medicated bark, stood for centuries ready

to give her antidote for malaria; but this power was unknown and unused until modern times. The oils and juices of a thousand plants have given to medicine their powers to destroy germs or neutralize their ptomaines. While much has been given for the asking, much more remains to yield disease-preventing and health-restoring power to the earnest, active searcher into nature's secret resources. On the mountain tops, on the sloping hills and in the valleys of Tennessee there may be plants growing whose properties, if known and used, would surpass, in power to prevent or cure disease, anything that has ever been brought from any clime. How these secret forces may be extorted from nature's hidden grasp, and by whom they shall be given to medicine, remains to be seen. Some of our young men within the coming year may woo the forest and the field and win therefrom something new that will be of service to the suffering world.

Rivalry in investigation is one factor in the march of progress. One possessed of this quality, like the mastiff, is conscious of his strength and faces him whom he opposes. He imparts some of his own courage to his contestant. At the end of the contest right wins and the late contestants should enjoy the results together.

Energy and industry are more powerful in the life work of a physician than are the circumstance of high birth and the environment of great wealth. The story of the lives of America's most noted medical men tell to us too plainly that they were not born into the proud positions that they attained; and they were not wafted there by some gentle, uplifting breeze. At least one of the most noted medical men the South ever produced, spent his earlier days on the old farm among the pines of South Carolina. Fired with the thought that there was a greater work in a broader field awaiting him, he left the old home with only a few dollars in his pocket and walked the weary miles that intervened between that home and the city of Charleston, that he might there commence his medical education. A less promising outlook could have hardly presented itself. His inborn capacity for work was not allowed by him to remain dormant; but his acquired habits of industry made of him the power which he became. Couple industry and capacity together, no mountain is so high that it may not be climbed; no plain so wide that it may not be traversed. By such an one every opportunity is transformed into utility; every obstacle is brushed aside with the broom of determination.

If all the latent energy—the inborn capacity—of medical men could be transformed into manifest power, by the magic touch of the hand of industry, no known cyclometer could record the revolutions of the wheels of medical progress.

The Medical Society is one of the most powerful factors in both personal and general progress. Its existence presupposes that the members have accomplished all that is required of them, in the prescribed courses of a medical college. There may be ever so much fire in a flint, yet without friction it can not be called forth. The Medical Society is designed to bring out the fire of thought from the reasoning centers.

The ideal medical association probably does not exist, and yet is a possibility. It is not my purpose to depict a perfect organization. The chief design of every medical society should be the advancement of

knowledge and the enhancement of skill. Its doors should be wide open to all honorable members of the profession, in the territory it covers. Bigotry and envy should not only not be placed to guard these portals, but they themselves should be prevented from entering, because both are enemies to progress. Fraternal feeling and professional propriety would be a sufficient safe-guard. The password should be "honorable medicine;" and the motto: "We will walk together in the pathway of progress." A rightly organized and properly conducted local society contains the germ of power. Each member, like the children of one family, feels at home, and basks in all the freedom and ease that the word home implies. They get training in this school that fits them for the college of the State society where they may find even broader and better opportunities for advancement. The smaller organization should bear a definite relationship to the larger; and their workings should harmonize. Both should be governed by laws having in them the same spirit of progress. Continuously in training in the local and State societies, every member should unite his powers with those of his fellow in perfecting the national organization. What a power these several organizations would become if only their full importance was appreciated by all members of the profession and by the laity. Some good but misguided men will not attend medical meetings. One does not often read in the obituary of such a man that he invented a lever for lifting the world of medicine to a higher plane. The immediate duty a physician owes to the public may often prevent his attendance at medical meetings; but when he can attend, and does not, he fails in the performance of a duty he owes to the public, to the profession and to himself. May the day speedily come when medicine can claim an organization in every city and county; when State societies shall have on their roll the names of all members of every local organization; when that grand ASSOCIATION, the AMERICAN MEDICAL, shall be constituted of all the members of all the State societies.

Medical Colleges have aided in the progress of the past, are doing better work in the present and will accomplish still greater good in the years to come. The medical schools of to-day are greatly in advance of those of even a decade ago; and the best schools of one hundred years ago are as nothing in comparison with the most advanced schools of to-day. If the medical colleges of the past, with their limited facilities for imparting instruction, turned out men who grew to be giants, what ought the schools of to-day do? Men towering above their fellows in medicine in past centuries, were few, and because of their fewness they attracted the greater attention. Larger medical giants, but more of them, are found in modern medicine. They attract less attention than in the past because they are so much more numerous. Our great men of to-day far surpass the greatest of other centuries, both in the depth and extent of their knowledge and in their power to apply it. Graduates of a few weeks ago know more of medicine than Galen ever dreamed of.

While medical colleges are still not perfect and should be further improved, on many lines, a greater care should be exercised in scrutinizing applicants for admission. A man to enter on the study of medicine should have much of the quality known as "mother wit," or common sense; he should be trained in literature and in the sciences, at least up to the point of development of his thinking powers; not only should

he be mentally sound but he should also be morally pure; and he should feel toward medicine somewhat as Paul felt when contemplating the ministry: Woe is me if I practice not medicine. No young man should be encouraged to wield the surgeon's knife or dole out doses for disease who is better fitted by nature and acquirements to tend sheep on the hillside or herd cattle on the plains; to build houses for the people to live in or make clothes for them to wear; to construct cars for commerce or man ocean steamers. There are a thousand and one callings in life ready to honor men, and from which men can get honor if they faithfully follow them.

Medical journals are streams of water for irrigating the garden of thought. The vitalizing fluid of the profession is continually coursing through the pages of our periodic literature. Sometimes this stream is poisoned by the plasmodium of egotism which now and then gives the reader a chill; sometimes it is made to lose its strength-giving power by the germs of the envious or the spores of one gifted in ridiculing. With all their faults journals are a necessary factor in the progress of medicine. If they were fewer in number they might be better. If those who imagine themselves gifted with editorial powers were really thus endowed, journalism would be on a higher plane. Fortunately the law of the survival of the fittest is continually doing its work. While a man is expected to buy the journal he reads he is not compelled to read all that he buys. The wise reader separates the trash from the treasure and appropriates only the latter. One of the duties of the editor, which is too often neglected, is to refuse the bad and infuse the good. He must read all that he would publish and should always have the courage to endorse the true and condemn the false. This he can do in editorial or in head-line. At a feast, the host can not equally commend all the viands he may place before his guests; but his action would be condemned should he set before them a dish he might know to be dangerous. But after all, the mental pabulum offered in medical periodicals is made up largely of contributions from subscribers. How much better these contributions would be if the prime object in presenting them was the making of leaves in medical literature for the healing of the people. The mission of the medical journal will not be brought to an end until medicine shall stand a perfected science.

Books are as essential to medical life and activity as bread is to physical force. Books may be poor in matter and style, as bread may be bad in quality and kind. As bad bread brings physical discomfort and predisposes to physical inactivity, so a poor book depresses mental power. Discretion in the buying of books is a necessity; the buying and the reading of good books tend only toward advancement. A good book is a storehouse from which all may draw without danger of exhausting. Of the making of books there is no end. Even one's enemy may write a book, if so to him, of course, the book would be a bad one. While the profession can not limit the making of books it is fortunate that it can control, to a large extent, the sale. Unprofitable books die with the first edition unexhausted, bequeathing to their authors no estate. The truths contained in good books will endure while time lasts. An individual book may not reach many editions, but their contents in some other form will extend across the stretch of time, and will always add to the speed of progress.

Enthusiasm has always been and will always be the spirit of progress. Its correct meaning is not always in the mind of the man who uses the word. The term crank or maniac would aptly apply to some who are miscalled enthusiasts. If we mean what we say when we call a man an enthusiast, we should have a feeling when before him, akin to that which possessed Moses when he stood before the burning bush, for he knew that God was in it. Not less certain is God in the genuine enthusiast, burning within him but not consuming him, a marvel to angels and men. It was in the power of Moses to have laughed at the bush ablaze, and to have walked from it with covered feet, but if he had so acted he would never have learned the lessons that made him the leader of his people, and the framer of laws for the nations of all subsequent time. The wisest as well as the humblest may learn lessons from the enthusiast that will be both helpful and enduring. Deliver medicine from cranks and maniacs who can but retard her progress, but give her more men who believe that God is the author of all truth; and, that for the general good of mankind, he sometimes takes up his abode in a man, firing him with an almost consuming zeal. When studying the firmament of medicine would that we could all cry out with the astronomer, as he gazes upon the stars, "O God! I am reading thy thoughts after thee." The plan of redeeming the people from disease is of Divinity, as is the saving of their souls from damnation.

The general progress in medicine is only the sum total of progress of individual medical men. Throughout the history of medicine there have been men who have created epochs and inaugurated eras. Harvey's discovery of the circulation of the blood was an epoch, prior to which medical thought groped in an uncertain light. The era of rational medicine dawned when Harvey enunciated the result of his investigation. The wonder has never ceased that the circulation of the blood remained so long unknown. Jenner's discovery of vaccination marked an epoch; but the era of immunization starting with it, continued in its morning twilight until the work of Pasteur caused it to break forth into the brightness of day. The noon-day of this era has not yet arrived. Throughout the coming centuries men imbued with the spirit of Pasteur's work, will go on investigating with the microscope and the test tube, and experimenting on the lower animals, until in due time, the people who will, may become immune from disease. The medical world stood still when told the story of McDowell's daring, and she has not yet recovered from the astonishment excited by the brilliancy of the era of abdominal surgery, which he inaugurated. The wonder will never cease that, for so many centuries, appendicitis and ovarian growths were permitted to send their victims trooping to an untimely grave, because of the unfounded fear that a puncture of the peritoneum meant death to the victim.

Thus we might speak of scores of epochs and the eras that have followed them. The men who moved in these matters simply uncovered principles as old as creation. The streams which they tapped when opening these well-springs, had always been connected with the great ocean of truth, and were only just beneath the surface. Thirsting for these waters, God-guided they digged deep enough to find them. Medicine and the world have been made richer by their labors.

Not all the hidden streams of truth have yet been

found. May it be the happy fortune of some who hear me to open up new fountains for refreshing the world.

Do we look longingly to the proud position of men who have attained eminence in medicine, without a thought of the rugged pathway they had to travel? We could not enjoy the one, if we would shrink from the other. Men must labor to climb, and wait to reach, the mountain tops of greatest usefulness.

Throughout the centuries medicine has been building her own monument. Before Harvey the work done only served to clear the ground and prepare the foundation. The corner stone of the superstructure is Harvey's discovery. Stone after stone has been added as discoveries have been made. As each tier stands completed, there is room for fewer stones in the one to follow. Some unenduring stones have been placed, but these have served to let the building go on. The rain of observation, clinical experience and legitimate criticism will cause the inscriptions on unsound stones to fade away and the stones themselves to crumble. Other workmen will be ready to remove these and in their places put material that will be more enduring. Some inscriptions will grow dim from the accumulated dust of neglect; but some one will come along and, with the breath of enquiry, will blow the dust away and make the reading clear and sharp again. The work of building goes on, some of the workmen preparing stones to place in the superstructure, but the great majority furnishing the uplifting power of encouragement and the cement of coöperation. The time will come when this monument will be ready for the placing of the capstone. This ceremony commemorating the final discovery necessary for making the science of medicine complete, will be performed as the millenium dawns, amid the applause of a world redeemed from disease.

ORIGINAL ARTICLES.

SPLENECTOMY STATISTICALLY CONSIDERED, WITH REPORT OF CASE.

Read before the Southern Surgical and Gynecological Association,
at Washington, D. C., November, 1895.

BY RICHARD DOUGLAS, M.D.

PROFESSOR OF GYNECOLOGY AND ABDOMINAL SURGERY IN MEDICAL
DEPARTMENT OF VANDERBILT UNIVERSITY.
NASHVILLE, TENN.

Assuming that the Association is deeply interested in the evolution of abdominal surgery, I presume to trace the history of splenectomy which will reveal forgotten facts established by the surgeons of old, which challenge the criticism and shame the technique of the most modern.

Physiologists are yet discussing the rule that the spleen plays in the animal economy, a question that was practically settled by Viard about the middle of the sixteenth century, he having removed the spleen from three patients, all of whom made perfect recoveries. Some twenty years before, Zacarelli appears as the first surgeon who successfully removed the spleen. These cases were not generally published and but few had the temerity to follow such brilliant leaders. As a consequence in the next two hundred years we find but twelve splenectomies. A large percentage of these were for wound with a protrusion of the organ. From 1800 to 1876 I find 28 splenectomies recorded with wide intervals. The next decade

yielded about seven per year. In 1888 it was the fad of the day, 21 operations being reported in that year, the work chiefly of Italian, German and French surgeons. Their mortality, over 50 per cent., was not encouraging, and since that date we have had only 45 operations, a very small number when we consider the rapid progress of abdominal surgery and the immense amount of work done in this special field. We must conclude then that splenectomy is not a popular operation, at least with those surgeons who operate for statistics. The consensus of surgical opinion seems somewhat adverse to this operation. I hold that such a position is erroneous as it is based upon statistics considered in the aggregate. If the proper analysis of these statistics be made and due consideration be given to the associate general condition, we can establish the fact that under certain circumstances the operation is justifiable.

Gathered from all sources I can find on record 194 splenectomies. Of these 126 were females, 57 males and in 11 cases the sex was given. Furthermore we find that in 46 cases the operation was undertaken for wounds or injuries. Of this number 26 were males, and 14 females. If we deduct these we find that the ratio of splenectomies for disease is 31 males to 112 females, showing the latter sex to be much more predisposed to disease of the organ.

Recalling that the weight of the adult spleen is only about seven ounces, we are awed by the pathology that so perverts nature as to magnify it into 8½ pounds, the largest spleen ever removed. The operator was H. S. Brown of England; the condition was leukemic hypertrophy. The patient died five hours after the operation, probably from hemorrhage. The largest spleen ever removed successfully weighed 11 pounds; the operator was Franzolini.

The size of the diseased organ has an important bearing upon the prognosis. In 41 cases in which the spleen weighed 2 pounds, or more, the mortality was 68 per cent. We should at least consider these figures in advising operation. Of the 194 cases eight are not entitled to be ranked as splenectomies, the operation in these cases being partial splenotomy for the removal of the protruding portion after wounds and hernia. This reduces the total number of splenectomies to 187.

We may make a pathologic classification of these cases as follows: Leukemia, 36 cases; 31 deaths, 5 recoveries. In only 7 of these cases do the data show a microscopic examination of the blood. Doubtless this investigation was made in many others but it is not so recorded and I am forced to accept such statements as "leukemia," "leucocythemia" and "leukemic spleen" for the diagnosis and classification. In this class we are at once confronted with a mortality of 86 per cent, which unless we can discern something radically wrong in the technique, places the leukemic spleen out of the pale of operative possibilities, and we dare not charge this when such masters as Péan, Czerny, Wells and our distinguished American, Roswell Park, were the operators. Of the 31 deaths 16 were positively stated to be secondary hemorrhage, 9 others died from shock, and we all know that in abdominal work this term is only too often synonymous with hemorrhage. Should not this establish the fact that leukemia is a general blood disease of which the hypertrophied spleen is an effect and not the cause? These patients are hemophiliacs and leukemic spleen should be eliminated from the field of operative inter-

ference. Since we have only 5 successful cases of removal of leukemic spleen, their paucity entitles them to detail record.

Case 1. Operator, Franzolini; date 1881; time of operation, twenty minutes. Patient, female, laborer, aged 22.

Diagnosis: Abdominal tumor from childhood, suffered from gastralgia, from 12 to 14 ascites and edema in lower extremities. Menstruated at 17, scarce and irregular. Symptoms of jaundice, no intermittent fever. At the beginning of 1879 dull pain in upper quadrant to left of stomach. Tumor hard, very little or not at all movable, obstinate vomiting, acute pain prevented rising to feet. Blood rich in leucocytes five times to normal. No albumin in urine.

Operation: Prepared by purgative pills; diet exclusively flesh for three days. Incision in linea alba 22 c. long leaving umbilicus to right, one half above, one half below. Splenic artery size of index finger, could introduce thumb into splenic vein. Ligation with phenicated silk: little blood lost; suture. Complete recovery.

Remarks: First successful operation in Italy. Spleen normal in color, quintuple in size. Removing 200 gr. of blood it weighed 1,526 gr.: 26 c. long, 16½ c. wide, 7 c. thick. There occurred forty hours after operation small dripping of blood from vulva: one year later blood almost normal.

Case 2. Operator, Assaky; date, 1888; time of operation, 1¼ hours. Patient, female, age 26, married at 18, several children.

Diagnosis: Abscess of breast after first delivery, edema of limbs after last. Malarial fever at 12, inflated abdomen after the disease. Tumor in the splenic region, constitution weak, mucous surfaces pallid. Both pupils dilated, temperature normal, no edema except varicose veins. Mammæ voluminous. Intestinal functions normal. Linea alba pigmented, superficial veins dilated.

Operation: Incision on the median lines of the umbilicus to near pubis, 12 c. long, hemostasis. Incision prolonged above the umbilicus 4 c., catgut, chlorid of zinc, cautery. There were 18 superficial ligatures, 14 more profound, 9 in the peritoneum. Recovery.

Remarks: Blood, 5,000,000 corpuscles in cubic mm. White to red in proportion 3 to 100; weight 2,410 gr., size 35 c. long, 42 c. wide; measure on concave side 28 c. long, 17 c. wide; 7 c., 1½ c., 5½ c. thick.

Case 3. Operator, Ceci; date, 1893; time of operation, one-half hour. Patient, female, age 13 years.

Diagnosis: Tumefaction of the stomach from infancy. At three years put on milk diet until stomach became normal. The malady began two years back, attributed to a fall. She became pale, gums bled easily. Ossa normal, muscles weak, but little developed, adipose tissue thin, aspect meagre, senses normal. Abdominal tumor hard, smooth, roundish, oblique. Lower temperature over tumor.

Operation: Chloroform anesthetic, median incision to left of umbilicus 28 c. from xiphoid appendix to three fingers of pubis; a second 14 c. transverse and oblique parallel to left costal arch: distance 6 c.; ligation of splenic artery, excision of much splenic substance so as not to injure stomach; catgut ligature. Liver normal. That part of the capsule that was in contact with the stomach was left intact so as to avoid hemorrhage. Recovery.

Remarks: Weight of spleen without blood 1,300 gr., 25 c. long, 15 c. wide, 6 c. thick. Blood before operation, red corpuscles 3,592,000, white 15,000, hemoglobin 60. Blood after operation, red 4,250,000, white 15,000, hemoglobin 65. Removal of pus after operation by puncture, hemorrhage, fever, 300 gr. purulent fluid removed from splenic cavity.

Case 4. Operator, Lindfors; date, 1892. Patient, female, age 20, peasant.

Diagnosis: Constitution weak, temperament lymphatic, five years before noticed increase of abdomen, specially of left side. Very round, acute pain, left part of abdomen occupied by tumor. Elastic, ovoid, very movable, 29 to 17 c.; circumference 25 c. Blood, 1 white to 250 red.

Operation: Chloroform, afterward ether. Incision 18 c. above umbilicus from right to left, a vertical incision from upper angle 6 c. to left side of angle. Abdominal walls divided successfully, hemostasis with care before opening peritoneum. Single adhesion to omentum. Omentum, etc., retained by sterilized gauze. Ligation of pedicle with aseptic silk in six divisions. Almost no loss of blood; suture completed. Recovery.

Remarks: Treatment four weeks previous to operation fortifying and stimulating. Weight without blood 116 gr.; length 25 c., breadth 15 c., thickness 7 c. Histologic examination: hypertrophy of fibrous element and diminution of pulp. Result:

augmentation of white globules, diminution of red, especially hemoglobin. No augmentation of thyroid and lymphatic glands.

Case 5.—Operator, Hartman: date, 1894. Patient, female, age 40, two miscarriages, no children.

Diagnosis: In iliac fossa and ascending to within one-half inch of costal arch, tumor flaccid, movable transversely from one fossa to the other. No area of dullness of normal position of spleen. Swelling of abdomen, continual vomiting. Was suddenly seized with meteorism. Headache of frontal type and so severe as to prevent sleep.

Operation: A sub-umbilical incision was made in median line, no attachment of spleen was found except by pedicle. It was lamelliform. The splenic artery was ligated, and then three other threads were passed, the last one constricting the whole pedicle en masse. The distal end of the pedicle was then tied near the spleen and cut between the last ligature and the others.

Remarks: April 7, hemoglobin 108, leucocytes 1 p. to 150, red 4,850,000; April 9, hemoglobin 90, leucocytes 1 p. to 137, red 4,400,000; May 20, hemoglobin 105, leucocytes 1 p. to 200.

The fortunate operators of these were Franzolini, Assaky, Ceci, Landfois and Hartman. That you may form some idea of the hemotaxis demanded in these cases chlorid of zinc, actual cautery and 41 ligatures were required to control the hemorrhage, from the pedicle alone. In Assaky's case there were no adhesions.

In forming the second class, that of malarial hypertrophy, I accent the diagnosis as given in the report and if it is not expressed I have relied upon the history and symptomatology. In none of these cases was the plasmodium malarie found. Under this head we have 40 cases, 24 recoveries and 16 deaths. To these I wish to add my own case which I trust I may be permitted to report in detail.

Mrs. J. S., age 33, housewife, multipara; native of Tennessee, family history good, has suffered occasionally with menorrhagia, but more recently from amenorrhoea. She had malarial fever when 12 years of age, for the last three years she has lived in the western portion of the State on the banks of the Mississippi. She has suffered during this time with frequent attacks of intermittent malaria. In July, 1895, she had remittent fever lasting five weeks, from which she apparently recovered. About August 1. last, she suffered from acute pain in the left side. A tumor was then discovered in that region about the size of the fist. The tumor grew rapidly, and on October 8 she consulted me. Physical examination revealed a smooth, elastic, movable tumor, filling the left lateral region of the abdomen. Edges sharp and notched. It frequently changed its form: at times it appeared flat and smooth; again it would rise up into a sharp ridge extending from ribs to symphysis pubis. There was absolute dullness over the tumor. Vaginal examination revealed the uterus forward, the pelvis filled with a smooth hard mass, which upon change disappeared from the pelvis and occupied the left iliac fossa. She suffered with paroxysmal pain, a sense of weight and dragging in the left side, flatulency, nausea and occasional vomiting. There was some emaciation and slight anemia. There was no adhesion, ascites, vertigo or insomnia. The blood examination was conducted by Prof. W. M. L. Coplin in the laboratories of Vanderbilt University, and appears as follows: Blood examination case of Mrs. S. by Prof. Coplin: Date of examination, Oct. 9, 1895; number of red corpuscles, 3,800,000; number of white corpuscles, 31,000; ratio, 1 to 123; per cent. of hemoglobin, 65. The red cells normal in configuration: no large or irregular cells; leucocytes almost exclusively of the large polynuclear type, only a few mononuclear white cells being present.

The diagnosis was malarial hypertrophy of the spleen, and after due preparation the abdomen was opened by lateral incision at outer border of left rectus. The incision was about six inches long. The spleen was found displaced and free from adhesions, its pedicle was secured by interlocking ligatures. The pedicle was severed close to the organ. As additional security against hemorrhage ligatures *en masse* were employed, also individual deligature of splenic artery. After removal of the spleen bleeding from the abdominal incision, which before was insignificant, now became very profuse and required several ligatures. The peritoneum was closed by separate silk sutures, the abdominal wall coapted by the usual interrupted silkworm gut sutures. The post-operative history is a very

stormy one. For the first twenty-four hours after operation the behavior of the patient was very satisfactory, pulse 122, temperature 100, respiration normal. The stomach quiet, urine secreted, 9 ozs. During the second day the patient restless, occasional vomiting, pulse 130, temperature 99, respiration 28, abdomen flat; urine secreted, 16 ozs. On the third day the patient became very weak, extremities cold, pulse 150, temperature 100, respiration rapid, 40, very shallow with attacks of dyspnea. During the twenty-four hours of the third day, only 2 ozs. of urine secreted. Some pain in the lumbar region, slight tympanitic distension of the abdomen. This was very peculiar, being entirely subumbilical. On the fourth day patient very dull, sleepy and slightly delirious, pulse improved, 120, temperature 100, respiration 36, but no dyspnea. Complained of severe pain in right side of abdomen and chest, depression and vertigo. Urine secreted 12 ozs. Fifth day general condition much improved, pulse 92 and full, temperature normal, respiration still rapid. Peculiar subumbilical sausage tympany marked. Bowels acted copiously. Urine secreted, 30 ozs. in twenty-four hours.

During the succeeding ten days patient suffered intensely with pain in left hypochondric region and adjacent area of the thorax; uncontrollable diarrhea, was drowsy and occasional vomiting. Tongue became dry and red, sordes appeared and rapid emaciation occurred, picturing in every way the closing scene of typhoid fever.

On the 14th and 15th days she passed a number of large, bloody and fluid stools, her pulse and temperature remained the same. The pain was relieved, tympany subsided and the brain symptoms disappeared. She expressed herself as much better. Marked and rapid improvement in general condition followed. All functions become normal.

One month after operation she was out of bed and looked ruddy and well and was in infinitely better condition than before the operation. Aseptic union of the wound throughout. Seven months later the patient is in good health.

The blood of Mrs. S. was examined by Professor Coplin and gave the following results:

Oct. 9, 1895, red corpuscles, 3,600,000; white corpuscles, 31,000; per cent. of hemoglobin, 65. The red cells normal in configuration, no large or irregular cells. The leucocytes are almost exclusively of the large polynuclear type, only a few mononuclear white cells being present.

October 13, operation.

October 19, red corpuscles 3,000,000; white corpuscles, 6,000; per cent. of hemoglobin, 60. Red cells somewhat irregular; a few microcytes and megalocytes and many of the normal-sized red cells pale, a few almost phantom. While the leucocytes are almost diminished in number their character is also changed; instead of the large polynuclear cell of the previous examination, the white cells are mostly of the lymphocyte type.

November 2, red corpuscles, 2,500,000; white corpuscles, 16,000; per cent. of hemoglobin, 50. Red cells more nearly normal in type; very few irregular cells. Leucocytes mostly of the large polynuclear type, and very much as they appeared before operation.

November 9, red corpuscles, 2,640,000; white corpuscles, 18,000; per cent. of hemoglobin, 50. Same corpuscular condition to be noted as that recorded in examination of November 2.

The third series of cases which I find it difficult to classify, for want of a better name, I designate as simple hypertrophy. In these cases there is no associate blood diseases, yet I would suggest that sufficient attention has not been given to the condition of the other viscera, especially the pancreas and the liver. In an investigation upon anatomic conditions alone we could assume that splenic hypertrophy would follow disease obstructing circulation in this organ. In a careful analysis of the recorded cases of simple hypertrophy, I can find allusion to the liver in only three. I question if this organ is not entirely overlooked in the diagnosis. In seeking to discover a

cause for this so-called simple hypertrophy we note that the organ is found to be "displaced," "wandering," "movable," "ectopic." At once the question arises: Is this displacement the result of the increased weight, traction and elongation of the pedicle, or have we in some instances, a congenitally long pedicle whose vessels are constricted by the mobility and changed position of the spleen, leading to pulp engorgement. Of 59 cases of splenectomy for simple hypertrophy 34 recovered, 25 died, a mortality of 42 per cent.; 9 of the deaths were due to hemorrhage, a preventable accident. With due precaution the mortality should have been 28 per cent.

Neoplasms from the fourth group: As primary growths they are rarely met with in the spleen. I can collect only five cases of sarcoma which may be thus tabulated: Billroth, female 43, primary sarcoma, recovery; Wagner, female 27, primary sarcoma, recovery; Helmouth, child, primary sarcoma, death; Frisch, female 31, primary sarcoma, death; Flothman, male 44, primary sarcoma of mesentery and spleen, death.

In all of these cases the diagnosis was corroborated by microscopic examination and can not be questioned. We note that four of the patients were in middle life, only one a child. Billroth in recording his case remarks upon the infrequency of primary sarcoma in the spleen.

The next pathologic condition demanding splenectomy is echinococcal cystoma of which there are six cases, four recoveries and two deaths. Simple cystoma of the spleen has been met with by three operators. Péan, Wells and Gussenbough. Péan's and Wells' patients were women. The tumor was diagnosed as ovarian. Gussenbough's patient was a boy of 14. All these cases recovered.

In 1581 Viard is reported to have removed three displaced degenerate and dried-out spleens; just what that pathology is I leave you to imagine. All these cases recovered and were the second series on record. Of primary abscess and sloughing of the spleen, not due to traumatism, there are three cases with three recoveries. I found throughout the literature of this subject, one case each of syphilis, primary tuberculosis and fibroid degeneration of the spleen. Death occurred in each case.

Two cases of floating spleen, normal in size, are reported: one death and one recovery followed their removal.

One of the most frequent conditions demanding splenectomy is injuries to the organ by contusions or stab wound. After wounds of the abdominal wall, the spleen often herniates. The protruding part quickly becomes gangrenous. Under the head of wounds we have 43 cases, 32 recoveries and 11 deaths. While these cases appear in literature as splenectomies, in 8 of these the protruding part was removed; all of this number recovered.

Clinical memoranda are not always as clear as one would like upon the question of diagnosis. In many records the reporters are most artful in their phraseology, not declaring a diagnosis nor confessing error nor ignorance. In a summary of cases extending over a period of three and a half centuries it is a little difficult to gather exact data. I find only 99 cases recorded sufficiently in detail from which we may draw conclusions as to a diagnosis. Of this number it appears that a diagnosis of splenic enlargement was fully determined in only 57 cases. In 24 cases it is questionable if a diagnosis was made, in the remain-

ing 19 cases there was absolute error of diagnosis. I can gather only 15 records of blood examination. In these the investigator seems to confine his work to estimating the relation of white and red corpuscles, without considering the character of the corpuscles or the amount of the hemoglobin. From this table we note that in three cases there was decided increase in white corpuscles after operation, with a diminution of the red. In three other cases there was a gradual decrease in the number of white, while the red remained as before operation. These data in part accord with the conclusion of Vulpins, who claims that after the removal of the spleen there is a leucocytosis, a temporary increase of white corpuscles.

It is held by physiologists that the spleen in the adult in conjunction with the red marrow of the bones plays an important role in the formation of red blood cells, yet in the few cases analyzed in which an accurate account of the blood was made before and after operation, in two there was slight increase in the number of red cells, in two others there was decided diminution. Concerning the function of the spleen with relation to the red blood cells, Emelianoff, in a recent number of the Archives of Biology of St. Petersburg, asserts that in the fetus the function of the spleen is the production of red cells, which function at birth is transferred to the marrow of the long bones. The change in function takes place gradually, that is through several weeks. But it is very doubtful if the organ in the adult, even after copious hemorrhage, takes part in the formation of red cells. One never sees red cells in the process of formation in the spleen. "It is very probable," says the same authority, "that the spleen takes an active part in the formation of hemoglobin." Vault and Jolyet, speaking from experiments upon animals, say that the removal of that organ is never productive of any derangement and therefore its function can be assumed by other organs, probably by the lymphoid glands. A careful examination of all cases recorded fails to yield a single case in which there was lymphatic enlargement following splenectomy. Upon like grounds I am prepared to accept the conclusions of Vulpins which is "The thyroid gland is not vicarious to the spleen." Exactly what division of extra labor is made among the various glands after removal of the spleen one cannot say; yet a few autopsies held upon the patients from one to three years after they have been deprived of their spleen, give us this information. Accessory spleens which at the time of operation were too small to attract attention have grown to the size of a walnut. Furthermore, fragments of the splenic tissue left upon the stomach and other viscera grew and preserved their normal characteristics. Schiff and Heitzen have endeavored to point out relationship between the pancreatic digestion and the function of the spleen. The pancreas of an animal deprived of its spleen loses its digestive properties. In contemplating splenectomies the surgeon must now feel he is sacrificing two organs. Since, however, beyond the cavil of the physiologist one can do fairly well without the spleen we are not likely to be deterred by their experiments. How well one's functions can be conducted without spleen is excellently illustrated in Tanton's case in 1700 (Morgani, De Sedibus et Caus. Morb. 111 ep. LXV), in which the spleen was removed from a child. She grew to womanhood and bore children. It does not appear in this case that the splenectomy in any way influenced the anatomic and physiologic develop-

ment of the endometrium or Johnson's lymphoid structure; yet ample evidence is obtainable that endometrial diseases frequently occur in the history of splenic disease.

The symptoms of splenic hypertrophy are divided into two classes, first constant and second occasional. Of the first we have progressively enlarging abdomen, pain, weight and dragging sensation, anorexia, nausea and frequently most obstinate vomiting, vertigo, insomnia, dyspnea, emaciation and anemia. The occasional symptoms are hematuria, epistaxis and hematemesis. I wish in this connection to remark upon the constancy of insomnia as a symptom. In almost every detailed report it is mentioned and may be explained, I think, by the existing anemia.

I do not think it necessary to discuss here the physical diagnosis of splenic tumors and hypertrophy.

Our acquaintance with intra-abdominal disorders is so much more intimate than formerly that in the future errors in diagnosis will be quite the exception. There are two complications which occur in the life history of enlarged spleen deserving special mention, torsion of the pedicle and ascites. I am able to gather altogether eight cases of torsion of the pedicles. To these if it were proper I would add a case reported by me in the *Medical News*, April 1890, of splenic hypertrophy with torsion of the pedicle, diagnosed as uterine fibroma with torsion of the pedicle. The woman died while preparations were being made for operation, the autopsy revealed the true nature of the case. Of the eight cases I reported all were women, six were multiparæ, two may have been though were not so stated. In four cases symptoms of torsion became quite manifest after labor or abortion. The symptoms of rotation of the spleen briefly stated are the following: Acute paroxysmal pain of the twisting character, more or less sharp; nausea, vomiting, frequently obstinate constipation so much so as to suggest intestinal obstruction; sausage tympany; tumor enlarges rapidly, becomes hard, tense and very tender. These symptoms remarkably simulate hemorrhagic pancreatitis.

The second complication to which I would call your attention is that of accumulation of ascitic fluid. It was present in eleven cases; nine of these patients died. Death was due to hemorrhage no doubt, though it is not so stated. The splenic hypertrophy in these cases was associated with, if not due to, hepatic cirrhosis, and after removal of the spleen by reason of the obstruction offered to the portal circulation there were double causes for increased vascular tension. Therefore a patient presenting this complication is predisposed to hemorrhage, a fact that should have due weight in determining the propriety of an operation. The first operation done in America was performed by Alston. Subsequently there were 28 additional operations performed, resulting in 11 deaths and 17 recoveries. Our honored fellow, Prof. E. S. Lewis of New Orleans, appears as the most successful American operator, he having removed the spleen in two cases of malarial hypertrophy. In one case the physical signs warranted the diagnosis of uterine fibroma. When the abdomen was opened he quickly discovered his error, but drew up the spleen, ligated its long pedicle and removed it. The second case was correctly diagnosed as an enlarged and displaced spleen. Both patients recovered.

Our honorable president Dr. Louis McLean Tiffany kindly gives me the following notes of his case:

Mrs. —, age 45, came into my care December, 1893, suffering from a tumor in the left side of the abdomen. It was freely movable from side to side as well as up and down, but always extended six inches below the left ribs. When standing the tumor presented below the navel in the middle line; toward the linea alba the finger could be pressed underneath the tumor recognizing a more or less sharp border, broken in two places by depressions which suggested that the tumor was an enlarged spleen. The history of the patient showed that she had suffered for years from irregular attacks of malarial fever and that the tumor had grown for seven or eight years slowly. It was thought at first that the attacks of malarial fever were accompanied by pain in the tumor. At present not only is discomfort complained of, but inability to eat and digest food also. Examination of the blood showed slight relative increase in white blood cells. The spleen was removed Dec. 29, 1893. An incision sufficiently long was made from the umbilicus downward to the left of the linea alba, and from the umbilicus upward and outward as far as necessary. The spleen at once came into view with a long pedicle. The omentum was adherent to the under surface and was tied off in segments. The vessels entering the spleen at the hilum were separately uncovered and tied. Two small spleens not larger than walnuts were left. All went well, the patient recovered without trouble. Examination of the tumor showed that it was 25 c. long, 14½ c. wide, 7 c. thick and weighed 11,000 gr. It was hard and inelastic: the capsule tense and much thickened. In places it was very opaque, apparently by fibrous deposit. On section it was of a dark red color, nearly black; the pulp could easily be pressed out leaving large and prominent trabeculae which crossed in all directions. Microscopic sections were stained with eosin and hematoxylin. They showed enlarged blood vessels, the spaces between the trabeculae contained large numbers of red corpuscles and a good many white ones. The sections looked like hemorrhagic infarctions, the walls of the blood vessels were thickened and infiltrated with small round cells. The capsule was thickened and infiltrated similarly, the glomeruli were seen with difficulty. Trabeculae were increased in size and number and infiltrated with round cells. There was much coloring matter present and there appeared to be a general increase in connective tissue throughout the whole organ. The appearance justified the diagnosis of subacute indurated splenitis. The blood was normal when the patient left the hospital.

AMERICAN OPERATORS.

Goodell, leukemia, death; Markoe, simple hypertrophy, recovery; Miner, simple hypertrophy, death; Powell, wound and hernia, recovery; Alston, wound and hernia, recovery; Myers, malarial hypertrophy, recovery; Markham, wound and hernia, recovery; Markoe, malarial hypertrophy, recovery; Strong, leukemia, death; Willien, wound, death; McGraw, malarial hypertrophy, recovery; McGraw, simple hypertrophy, death; Nilsen, simple hypertrophy, recovery; Deaver, traumatism, death; Simmons, malarial hypertrophy, death; Rod-dick, traumatism, death; McCann, simple hypertrophy, recovery; Conklin, simple hypertrophy with torsion, recovery; Bond, simple hypertrophy with torsion, death; Pane, malarial hypertrophy, recovery; Bark, leukemia, death; Saurason, malarial hypertrophy, recovery; Penrose, simple hypertrophy, death; Yourkin, simple hypertrophy, recovery; Stephen, simple hypertrophy, recovery; Lewis, malarial hypertrophy, recovery; Lewis, malarial hypertrophy, recovery; Tiffany, malarial hypertrophy, recovery; Douglas, malarial hypertrophy, recovery; total number 29, deaths 11, recoveries 18.

THE EXTENSION CORSET AND ITS INDICATIONS.

BY ALEX. C. WIENER, M.D.

CHICAGO.

Lewis A. Sayre revolutionized the treatment of tubercular processes of the spinal column by the propagation of absolute immobilization and freedom from pressure of the diseased portion. That the results obtained by his method were unprecedented is amply evidenced by the fact that his principles have made a triumphal tour around the civilized world and that the use of the plaster of paris corset has come to be considered indispensable in the treatment of Pott's disease.

The symptoms of tubercular infection of the spinal

column, first described by Perceval Pott in 1783, have been dilated upon by Sayre in so clear and scholarly a manner that every physician ought to memorize his words, so as to always have them at command; for how many beginners in practice fail to diagnose properly the early stages of Pott's disease and owing to their lack of skill expose themselves to the serious charge of perpetuating for life in a fellow creature a deformity which is the constant source of physical and mental agony? We are still further indebted to Lewis A. Sayre when we observe that his principles are now being applied to the treatment of tubercular diseases of the hip and knee joint, thus constantly lessening the indications for operative interference, so that the young patient may be spared an extensive operation, painful treatment and a tedious sickbed.

Although Sayre, Phelps and others have clearly demonstrated the utter uselessness of the Taylor brace, these bandages are nevertheless sold in large quantities to the public by truss makers, who apparently have faith in the suggestive value of such a support, as it is impossible for them to demonstrate that a real extension and support is exercised by an apparatus which slips down upon the pelvis or excoriates the skin when charged with the weight of the head and trunk. But unfortunately, unlike hysteria, Pott's disease is caused by infection with the tubercle bacillus and precious time is wasted in using worthless instruments, the serious consequences of which are not slow to make themselves felt.

A. M. Phelps in his valuable paper on Spinal Supports, makes the following remarks on this important subject. "Previous to Sayre's investigations the Taylor brace has been exclusively used for the extension and fixation of the vertebrae, but many disadvantages resulted from its use, in that a mother or nurse being able to remove it at any time often handled the child in such a manner as to produce traumatism and injury to the diseased vertebrae. Further, the steel bars had to be frequently removed or excoriations would occur. When they do give support, they are uncomfortable, which is one of the strongest arguments against their use in Pott's disease of the spine. In place of this troublesome instrument, which is devised in a hundred different forms, Lewis Sayre introduced the plaster of paris corset to be applied while the patient is hanging in Sayre's suspension apparatus.

"We all agreed," continues Phelps, "that the best orthopedic instrument ever devised is the human hand. Guided by intelligence it applies forces for the correction of deformity more delicately and perfectly than any inanimate object ever invented. Plaster of paris is applied to the deformity. While it is yet in a plastic state the hand molds it to the correct position and holds it there until it becomes hardened or set. Can you not see that now the plaster of paris is effective as a brace or support only in proportion to the amount of cerebral matter concerned in its use? In the absence of the latter it is worthless."

Phelps' specific statement of the requirements of a brace brings us to the leading principle of the extension corset, which was first made by Hensing. Every inch of the bars used in the construction of the corset must be fitted to the figure, so that when the various parts are put together no pressure will be felt anywhere on the underlying soft parts. The work of fitting and correcting must be prosecuted with untiring exactness, until every part fits the body snugly, rest-

ing upon it without pressure. Herein lies the chief objection. The vast amount of labor which every corset involves is the principal reason why these corsets will never supplant the plaster of paris corsets in the clinical practice. A mechanic can prepare the steel bars according to given measurements, but the real work, that of fitting inch by inch, must be done by the orthopedic surgeon himself with hammer and rule in hand and the anvil at his side. These instruments are of equal importance in the operating room of the orthopedic surgeon as are those which are used in operations. In this method in adjusting steel bars the requirements made by Phelps are complied with. Just as the plaster of paris is molded by the hand of the surgeon in applying the Sayre corset, so the surgeon guided by a thorough anatomic knowledge fits the steel bars to the configuration of the body, making ample use of his "cerebral matter," Phelps' paraphrase of common sense, for which a substitute never was and never will be found.

Extension Corset for lateral curvature of the spine.

A plaster of paris cast is taken of the patient while hanging in Sayre's apparatus. This cast filled with plaster represents the figure of the patient. A corset is cut according to measurements from French coutil, which should fit accurately but somewhat loosely, to leave room for the braces. The hip part consists of a steel bar which, starting backward from the os coccygis, runs upward to the spina posterior superior, and crossing the crest of the iliac bone laps over the anterior abdominal wall, terminating one inch above the Poupart ligament, thus riding, as it were, and resting on the crest of the iliac bone, with both shanks clasping the whole iliac region. A steel ring is then fitted in the arm-pit, upon which the shoulder rests firmly, as upon a crutch. After both these parts have been connected by steel bars, which must also closely follow the outlines of the body, so that their combined length will be greater than that of the spinal column, it is evident that, since the whole weight of the

shoulder and head rests upon the lower part of the corset, the deformed spinal column will first be relieved and then extended. After the spinal column has been raised so far that the given length of the side bars has been reached and no further extension can take place, the screws in the longitudinal slit of the bars must then be loosened, the space between the pelvis and the arm rest enlarged and fastened in this position. Thus, the correction conforms with the growth of the body as well as the improved condition of the diseased spine. The corset should always be drawn tight, fitting the body closely and if possible, should be worn at night. Elastic bands properly placed enhance the efficiency of the steel bars in the correction of the deformity.

At the end of his article Phelps gives the following indications for the different devices: 1, plaster of paris corsets for acute Pott's disease; 2, wooden corset for lateral curvature and cured or convalescent cases of Pott's disease; 3, the Beely corset for mild forms of lateral curvature, especially in girls; 4, the aluminum (Phelps) corset for permanent bracing; 5, the celluloid corset (Lorenz) in a way takes the place of aluminum.

Extension Corset, side view.

While fully recognizing the value of these various apparatus, more especially on account of the simplicity of their construction, still the superiority of the extension corset for permanent extension must be acknowledged, because the effected spine is equally relieved from pressure and immobilized. This is evident from the instantaneous cessation of the reflex muscular spasms and pain. The length of the side bars can be readily adjusted. The corset may be taken off for constitutional treatment with ease (baths, etc.). Above all, it does not in any way interfere with extensive open air exercise which is essential in the treatment of these affections. Hoffa and Heusner are the most enthusiastic advocates of the extension corset in Germany, while Lorenz, too, uses the Hessing device in the construction of his corset, excepting only that the pelvis bar is replaced by a capsule of celluloid. The Lorenz corset, however, is too heavy and inflexible and the celluloid casting does not conform to the subsequent changes in the trunk during the course of treatment, as does the elastic French coutil. If the seat of disease be at the thoracic or cervical vertebrae, a collar should be added which is wider at the back of the head and finds its support on the mastoid process

and forward under the lower jaw. Exactly in the center of the mastoid process a steel bar projects from each side which conforms accurately to the depressions between the muscles of the neck and the protruding collar-bone and reaches downward to the middle of the trunk. Here the bar is attached to the shoulder brace by means of an elastic band. The head may be immobilized or kept movable, according as the screws are drawn.

Admission to a hospital is desirable in having the corset prepared, so that the patient may be always on hand. Even after the corset is finished it is better for the patient to remain a few weeks longer, so that any defect may be noted and remedied and instruction may be given the mother or nurse as to the exact manner of fitting the corset.

It is easy to understand that at first patients, especially if children, feel uncomfortable in the corset. In the beginning, therefore, it is advisable to leave the corset on for only a few hours and to draw the string gradually until the maximum is reached. Care must be taken to distinguish between the feeling of discomfort which is common to almost every new garment and the actual pressure of a steel bar, which is indi-

Extension Corset, back view.

cated by a redening and soreness of the skin and must be relieved at once.

Constitutional treatment should go hand in hand with local treatment. The majority of children suffering from tuberculosis of the bones are afflicted with anemia, lack of appetite, a tendency to nervousness and weakness of the heart. They have a pronounced dislike of nitrogenous foods, *i.e.*, meat and eggs and frequently milk also. Obedient to this hint of nature I have for a number of years prescribed a vegetarian diet with strict exclusion of beverages and of medicines, containing alcohol and have had the satisfaction of observing an increase in appetite and subsequent gain in weight. Beginning with milk, rice and apple sauce we change to heavier foods as the children are allowed freedom of movement, such as buckwheat, oatmeal, barley, sago, spinach, peas, beans, potatoes, the fruits of the season raw and cooked, etc. Small quantities of rich unskimmed and freshly cooked milk may be given and raised by degrees until a quart a day is reached. Often Horlick's malted milk proves useful for a change. Cod liver oil combined with phosphorus, lactophosphate of lime (Merck's) and extract of malt or iodids should only be given after

the children have gained in strength and their use should be discontinued if nausea or loss of appetite result. An effective means of improving the appetite and general health is warm sea-salt baths. It is advisable to begin with washing the whole body with sea-salt solution in a well warmed room, the water being lukewarm in the morning and warm in the evening. The whole procedure should not last more than three minutes and the skin should be dried, not by rubbing with a towel, but by gentle touching, so as not to wipe off the salt crystals which are precipitated in the pores of the skin. When the baths are found to agree with the patients, full baths should be taken three times a week, the duration not to exceed five minutes and the temperature of the water being about 98 degrees. In proportion as the patient grows stronger the temperature of the water may be gradually lowered. In the beginning the baths should be warmer, about 98 degrees, and should not last longer than five minutes, especially if there is any complication of the heart. By degrees the temperature may be lowered to 90 degrees and the duration may be increased to thirty minutes. It is difficult to give any special rules in this connection. The frequency, duration and temperature of the baths are regulated by the condition of the patient and the good judgment of the physician. In general, baths should not be given more than four times a week and the temperature should not be under 90 degrees. The loss of calories from the system is not excessive. The stimulation of the peripheral nerves is so much greater in cooler water, which is of importance, first, on account of the strong irritation of the sensible nerve ends on the surface of the skin, as well as an irritation of the cerebral centers of sensibility, and, second, on account of hardening the system. By hardening we mean the accustoming of the nerves of the skin and of the mucous membrane of the upper air passages to exposure to cold, which leads to an increased generation of warmth with increase of appetite and stimulated metabolism in the organism and also stimulation of breathing. The salt contained in the water exercises a merely mechanical action, since after drying, the crystals of salt remain in the pores of the skin, where they act as an irritant on the nerve ends and blood vessels of the skin. For feverish patients there is no more reliable and gentle means of lowering the temperature and relieving the tormenting thirst as well as the debilitating night sweats. After the bath the patient should remain in bed for one hour and be careful to prevent perspiration, so that the pressure of the blood is not lowered to too great an extent and the heart's action weakened. Special care should be taken in the case of patients with complications of the heart and lungs. When possible visits should be made to the seashore during the season, where bathing in the surf, and the sea breezes exercise very salutary effects. The excellent results I have observed from the sea-salt baths makes me an enthusiastic advocate of this treatment in every case where there are evidences of constitutional disturbances either of tubercular or rachitic origin. But many mothers anxious that their children be restored to health as quickly as possible overdo the bathing to such an extent as to counteract the good effects. The physician, therefore, should insist on seeing the patient at least twice a month and should not allow the baths to be given longer than two months in succession.

In the natural course of tubercular infection of the

spine a cold abscess will be formed surrounded by spongy granulations which penetrating into the spinal channel press on the spinal cord. It is very rarely the case, however, that pressure symptoms alone attend degenerated and sunken vertebrae. In these serious cases, in which paraplegia and total paralysis of the lower extremities have developed, the immediate application of an extension corset is necessary, which must be worn day and night, or for which a weight extension on the head may be substituted at night. Laminectomy is justified only when the pressure of the tuberculous pus and granulated tissue has become so great as to paralyze the bladder and rectum, and the patient's life is threatened by septicemia due to bed sores.

Although a discussion of the operative treatment of Pott's disease is beyond the scope of the present paper, still it may not be irrelevant to state that from a critical review of the literature in this connection the ultimate results of this operation are not such as to warrant the procedure without positive indications. Beside septic infection, hemorrhage and the difficulty of access to the diseased part, a miliary infection has been observed in some and a return of the paralysis in others, although all pathologic symptoms may have disappeared with surprising rapidity immediately after the operation. Another fact which has not received proper attention is, that an edematous swelling has been observed at that portion of the spinal cord which corresponds in the diseased portion of the vertebrae, and this continued after the removal of the pressure and eventually resulted in a return of the paralysis of the extremities. This edema lasts about two years. As yet its anatomic cause is not demonstrated. It is not improbable that iodid of potassium may reduce this edema and in this way the mysterious specific effect of this remedy on paralysis in Pott's disease may be explained.

In so far as the spinal cord is relieved from pressure, there is certainly a promising future in store for the operative treatment of Pott's disease. Judging from the effects of operative procedure on the more accessible joints, however, one is inclined to doubt that such procedure will ever bring the process to a standstill, and, for the present, conservative orthopedic treatment will have the better results to show as its methods are perfected. The universal introduction of the extension corset together with Sayre's plaster of paris corset will mark a most important advance.

I will restrict myself to a few typical instances. The following case was referred to me by Dr. E. W. Lee in the accompanying letter:

Dear Doctor:—I herewith send you a boy ten years of age, whom I saw for the first time only a few days ago. I found him with a temperature of 102.5 degrees, pulse 140 weak and irregular, vomiting and constant nausea, so that he could not keep anything on his stomach. A tenderness was found in the upper cervical region. The head was turned to the right like a torticollis, almost resting on the right shoulder; loud bruit on the mitral valve. I suspected a local meningitis starting from a tuberculosis of the upper cervical vertebrae.

Yours etc.

E. W. LEE.

Passive and active motion of the head was impossible. No swelling was to be found. Digital percussio of the occiput and the subsequent rapid improvement fortunately failed to substantiate Dr. Lee's well founded suspicions. From the symptoms, I concluded that the process was seated in the atlo-axoid articula-

tion, and this was confirmed by the great tenderness in the region extending from the first to the third vertebra on the right side.

The boy was admitted to St. Joseph's Hospital and an extension with weights applied. The weights were gradually increased from one to seven pounds. Sea salt baths were prescribed and gave immediate comfort and relief. As soon as the vomiting had subsided vegetarian diet with plenty of milk was instituted. The corset was at once prepared. The boy was discharged at the end of four weeks, looking bright and well, with a gain in weight of eight pounds and wearing a tight but comfortably fitting corset with a leather collar attached, which held his head corrected to the left side. Without support the head had an inclination to turn to the right, but could be moved without pain, the tenderness of the upper cervical vertebrae on palpation having entirely disappeared. The apparatus he wears is almost entirely concealed under his clothes.

Karl B., Case 2.

How serious would have been the consequences had this boy been compelled to stay in bed or even wear a jury mast! With this strange-looking instrument he would have confined himself to the house frightened away through the taunts of his comrades, thus wanting the stimulus of outdoor exercise and cheerfulness, whose importance can not be overestimated in restoring metabolism and augmenting the vital forces in chronic diseases.

Through the kindness of Dr. Fischer I had an opportunity in Buda Pesth last September to examine a remarkable case of tubercular caries of the thoracic portion of the spinal column involving the second to the seventh vertebrae. Karl B., 28 years of age, has the following history: Both parents died of tuberculosis of the lungs. He had a kyphosis since his seventh year, which gradually and imperceptibly increased in size without causing him any pain. In the beginning of January 1891 suddenly without any apparent cause pain set in in the middle of the kyphotic part, which was soon followed by paralysis

of the lower extremities, the legs ceasing to act almost instantly. The reflex action in the legs increased, the sensibility decreased. When seated the patient held his shoulders so high that they were on a level with the tops of his ears. The kyphotic part formed an angle of 90 degrees. A lateral deviation was not noticeable. About one centimeter below the most prominent part of the kyphosis there was a painful spot, and from this point emanated the paralytic feeling above mentioned. The action of the bladder and of the bowels was not disturbed. Diagnosis: Tubercular kyphosis of the thoracic vertebrae, complicated with compression of the spinal cord. Every other means of treatment having failed he was admitted to

Karl B., with corset and collar.

Fischer's orthopedic hospital in Buda Pesth to be treated with an extension corset. Suspension of but a few minutes' duration relieved him very much and enabled him to lift his feet with ease, the kyphotic part becoming stretched about one centimeter and the spinal cord being relieved from pressure. At first the patient could hardly wear the corset, but he gradually became accustomed to it. After ten days the constant reflex contractions of the legs ceased and he made his first step in a frame support. To make the extension of the spine as effective as possible the patient was provided with a leather collar embracing the posterior part of the head and chin, by means of which the head was supported and the vertebrae stretched still more. When the writer saw the patient two years later, he walked about without a corset, only using two canes on the street. The pain in the back had left him and the reflex action and sensibility in the lower extremities were normal. His general health was very good.

In cases of lateral curvature of the spine in the sec-

ond and third stage, the extension corset has proven indispensable. In these cases the spinal column is only supported in order to prevent the muscles, which have been greatly strengthened by daily gymnastic exercises and massage, from again losing their tone through over-exertion. Special care must be taken to construct the corset so as to conform to the rapid changes in configuration. From the foregoing it is apparent that all patients suffering from injury to the spine and in need of temporary relief are enabled to walk about by the wearing of these corsets, whereas without this support they would have been compelled to remain in the extension bed. In this connection I would refer to my paper, "Ambulatory Treatment of Fractures of the Lower Extremities," published in the *Railway Surgeon* in February, 1896, in which the same principles were discussed.

So far we have been considering only diseases of the spinal column, whereas the universal character of the extension corset is still more in evidence in the successful treatment of an affection of the spinal cord, in the therapy of which even neurologists have achieved but indifferent success, that much investigated disease, locomotor ataxia.

Recent research has shed but little light on the nature of this malady of the posterior column, which in its first stages is characterized by symptoms so vague and baffling that only a neurologist is in a position to make an accurate diagnosis. Under these circumstances Leyden acknowledged that no plausible theory has yet been advanced for the progressive degeneration of the nervous system and that we must for the present be content to consider them as peculiar processes. Even the strenuous efforts of Charcot and his pupils to classify locomotor ataxia among the systemic diseases were futile. In the therapy of the disease, too, but little little progress has been made within the last decade, although it would have seemed, that the fact, that in about 80 per cent. of the cases the disease was preceded by syphilitic infection would have given rise to better results by the institution of an antisiphilistic treatment. The suspension method is the only original innovation, which has been made in the treatment of locomotor ataxia. Added to the electric treatment, which is imperative, it is a mechanical means of great value, although it is by no means all that can be desired. This mechanical treatment of locomotor ataxia was first employed by Dr. Motschukowsky, of Odessa, with great success, and his results were published in the *Wratsch* in 1883. Dr. Motschukowsky reached the following conclusions:

1. For two or three hours after suspension walking becomes easier and steadier. After eight or ten sittings it becomes permanently firm and steady.

2. The shooting pains cease entirely and do not recur even during thunder storms and changes in the atmospheric pressure. Some patients who had previously experienced much pain during north and northwest winds became entirely indifferent to the changes of wind.

3. The retarded pain current is considerably hastened, while the parasthetic feelings, such as chills, formication and girdle sensation subsided.

4. After twenty to thirty sittings there is a gradual subsiding of the ataxic symptoms. The Romberg symptom disappears, the tactile sense improves and the atrophied muscles increase in size.

5. Urination and defecation are once more under

the control of the patient. The quantity of indican in the urine decreases, the sexual functions are restored, the gastric pains become milder and less frequent.

6. In some cases the eyesight is improved; the pupils become more movable and dilated; there is a gain in weight. In no case has a return of the knee phenomena been observed, and no improvement has been noticed in the dilatory skin and muscle reflexions.

Motschukowsky has ascertained by exact measurements, that the length of the spinal column increases from one to three centimeters while suspended in Sayre's apparatus, in consequence of which the relation of the spinal cord to the spinal channel is undoubtedly altered, so that the nerve roots assume a more vertical position, though without being perceptibly stretched. Suspension also increases the pressure of the blood, the breathing becomes costal and the vital capacity of the lungs grows larger. Motschukowsky is of the opinion that the white substance not yet infected may preserve its physiologic functions for some time by favoring the establishment of collateral circulation. What Motschukowsky especially commends in his method is its mildness as compared with operative and mechanical stretching of the nervi ischii, which succeed in reaching but one part at a time and the first of which is frequently followed by trophic disorders, the second being annoying and painful to the patients.

As contra-indications to his method Motschukowsky enumerates the following:

1. Disease of the heart and compensative derangements.

2. Sclerosis of the arteries and aneurysms, anemia in a high degree and a tendency to faint.

3. Pulmonary cavities and emphysema.

4. Previous apoplectic, epileptic or epileptoid attacks.

The success of the treatment is less apparent in the first stages than in the secondary.

Charcot, in the *Progrès Méd.*, 1889, fully confirmed the statements made by Motschukowsky. Out of fourteen cases he had observed eight that were considerably improved by suspension. Wm. J. Morton concurs with him in the following words: "My experience leads me to confirm in every particular the results observed in the eight cases at Salpêtrière. We shall have to admit that the aggregate of improvements and cures, whether temporary or permanent, is far beyond that which has been attained by any other means, and for that reason this method must be regarded as the most signal advance yet made in the treatment of this hitherto intractable disease."

Weir Mitchell has modified Sayre's apparatus for this special case so ingeniously that even those seriously ill may be safely treated with it. Yet notwithstanding these indisputable facts the suspension treatment has of late years been entirely discarded, chiefly, in my opinion, because the majority of patients growing tired of frequent suspension even in the most comfortable apparatus, would not allow the physician to carry the treatment to a satisfactory end. Only recently, however, Dr. Brower, in an elaborate article published in *The Corpusele* in 1895, refers to the abandoned treatment in the following words: "My experience has taught me that suspension is of value in the stage of incoördination. I would recommend suspension treatment three times a week, lasting from

five to fifteen minutes, according to the effect on the patient. I think it should be continued as long as possible."

Bechterew is convinced that even where no anatomic changes are found in the eye the power of vision is materially increased by suspension. (*Neurolog. Centralblatt*, 1893; On the Influences of Suspension on Visual Derangements in Affections of the Spinal Cord.)

It is impossible to assert that the statements of men like Charcot, Brower and Morton are erroneous. Why is it, then, that the treatment of locomotor ataxia by suspension has been abandoned? When we consider that, although suspension should last but half a minute at first, and should only gradually be increased to thirty minutes, and further that the patient should be treated only every other day, the salutary effects of this method are nevertheless apparent in the extension of the vertebræ as well as in the probable stretching of the nerve roots, the question involuntarily arises: Why are not the vertebræ kept permanently stretched and the good effects perpetuated? No instrument is better adapted to this purpose than the extension corset, the application of which removes the contra-indications mentioned by Motschukowsky and does away with the disadvantages of the suspension apparatus. The corset should, therefore, be regarded as a permanent suspension apparatus, the object of which is to check the degenerative process in the spinal cord without interfering with the electric, medical and hydropathic treatment of the patient. In other words, the patient should continue under the specialist's care while wearing the corset, just as the treatment remains in the hands of the physician while the bloody nerve extension is made by the surgeon. In both cases the surgeon's skill is at the command of the neurologist.

The following case of locomotor ataxia is reported by Prof. Dr. von Jürgensen, Tübingen, Germany, who personally observed its progress with great care.

History: While taking the waters at Kissingen in 1884 the patient was suddenly afflicted with constipation and want of appetite. Later on a heaviness in the legs set in, the power of locomotion decreased and the carriage became stooping. In March, 1885, after having attended a dancing party he suddenly experienced a feeling of contraction and numbness in different parts of the skin, especially about the breast and arms, and at times the sexual functions were weakened. Evacuation was effected only by artificial means. Nervous pains were frequent. Treatment with massage and electricity and the use of the waters of Wiesbaden resulted in an improvement in the general health, but the above mentioned symptoms did not entirely disappear. In March, 1888, there was a severe relapse. He experienced a sensation of contraction at the throat, which made speaking and swallowing of food very difficult. He suffered from frequent and violent nervous spells. There was a rapid loss in weight. Professor Mendel, of Berlin, finding his treatment of little avail, recommended the wearing of an extension corset, which Hessing himself constructed. The neuralgic pains, the girdle sensation and the numbness of the skin rapidly disappeared. The appetite increased and digestion became normal. His gait became firmer. Although he had resumed his business vocations, it did not in any way retard improvement, and the patient could walk five miles without being fatigued. With the exception of a slight uneasiness when walking in the dark, he felt

perfectly well. His finger nails, which had previously been distorted, resumed their normal shape.

Equal success is not likely to be experienced in every case of locomotor ataxia, as 25 per cent. of the cases are not in any way, even temporarily, influenced by artificial stretching. In the remaining 75 per cent. of the cases which react more or less after a suspension of so short duration, permanent extension may be expected to effect a definite improvement in coördination.

The remaining diseases of the spinal cord—sclerosis of the lateral cords, diffuse chronic myelitis and chronic meningo-myelitis—will not be influenced by suspension at all, and permanent extension will also prove ineffectual. On the other hand, suspension will cause a material improvement in defective functions of the nervi erigentes which originate in the first to third sacral nerves and the center of erection, which is located in the lumbar part. In cases of paralysis after poliomyelitis acuta, it is necessary to use the corset in combination with supporting apparatus for the lower extremities, a description of which, however, would take up too much space for insertion in this article.

CONCLUSIONS.

1. The essential requirements for the successful treatment of Pott's disease, viz., extension and immobilization of the spinal column, are met in an ideal manner by Sayre's plaster of paris corset.

2. The Taylor brace does not meet either of these two requirements. It is therefore of no value in treating Pott's disease and for this reason should be discarded.

3. The extension corset acts like the plaster corset which is constructed according to Sayre's method, except that steel bars and French coutil are used instead of plaster. It fits as snug to the body as a plaster corset, and both form an outer skeleton, to the inner side of which the muscles of the trunk adhere closely. *a.* The plaster corset is preferable to the extension corset in the first stages of Pott's disease for children under 6 years of age, and its cheapness adapts it to clinical practice. *b.* The extension corset, on the other hand, can be readily adapted to the changes in configuration by readjusting the steel bars. It can be taken off with ease for constitutional treatment and at night, and it does not interfere with extensive outdoor exercise.

4. To insure the ultimate success of the treatment it is of the utmost importance that the surgeon himself adjusts the steel bars and exercises a general supervision, occasionally making such alterations in the fit as are deemed advisable.

5. The value of the discovery of Motschukowsky in the treatment of locomotor ataxia will not be appreciated to its full extent by the profession at large until permanent suspension by means of the extension corset has replaced temporary suspension.

Venetian Building.

FROM THE *Washington Star*:—"You feel very sluggish, do you not?" said the physician. "Doc," said the patient confidentially, "bein' ez yer me physician, I'll tell ye somethin'. I've been a professional pugilist in me time, an' between me an' you, that sluggish feelin' ye hear 'em talkin' so much about is gin'rally a complete bluff."

CONTINUOUS SUBMERSION IN THE TREATMENT OF INFECTED WOUNDS OF THE EXTREMITIES.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons, held at Chicago, Ill., Sept. 25-27, 1895.

BY FRED. J. HODGES, B.Sc., M.D.

CHIEF SURGEON C. & S. E. RAILWAY.

ANDERSON, IND.

Within the sound of my voice to-day are not a few of the men who have been conspicuous in their efforts to place surgery upon a rational basis; to earn for it a place among the true sciences. To such there can be no name so illustrious that its glamour can blind them to the defects of any surgical proposition or procedure, nor can I believe they will fail to consider and weigh the suggestions of even the humblest within the ranks.

Before such a body, not easily influenced by sentiment or selfish considerations, but zealous always for the best interests of our profession, I appear to briefly submit and support the proposition, that in continuous submersion we have the most rapid, thorough and reliable treatment for infected wounds of the extremities yet devised.

We are told that continuous submersion, by which I mean the submersion of a part for any considerable length of time from twelve or twenty-four hours up to as many days, has for years been very considerably practiced by German hospital surgeons and that it was introduced by them into this country at the St. Francis Hospital some time prior to 1872.

Such is undoubtedly the case, but the procedure has failed to impress itself upon the surgical literature of either country, as the only direct specific references to the practice which I have been able to find are articles by Frank Hamilton in the *Medical Record* for May 15, 1874, and in the January, 1873, number of the old Richmond and Louisville *Medical Journal*.

So far as the writer is concerned the treatment about to be advocated is original.

There came into my service in Cook County Hospital during 1888, a case which had originally been an infected (packing house) wound of the hand that had been poulticed, incised and drained. Later the forearm had been incised and through and through drainage practiced without improvement, so that when it came into my care the hand and forearm were everywhere infiltrated, swollen and sodden. The wrist joint was broken down, passive motion promptly eliciting the crepitus of denuded bone. The patient was by turns delirious from temperature, and maniacal from sepsis. He refused food and was sleepless, and exhausted to such a degree that seemingly death could not be postponed many hours. The nurses of one watch were stimulating him over to the next to escape having to lay him out. What was to be done? Amputation had been considered and dismissed by my predecessors, as necessarily fatal in his weakened condition. Every pocket and recess in the sloughing tissues had been reached and drained. The dressing had been changed from two to six times each twenty-four hours. Clearly no improvement was to be looked for in that direction. The condition seemed so desperate that I placed the arm in a continuous bath of dilute boric acid solution. In twelve hours the man's temperature had fallen from 104 to 99.5, and in twelve more he was perfectly rational and eating well. His further improvement was rapid and uneventful.

In what is known surgically as "infected wounds,"

there is usually present a "mixed infection." That is to say, there are present besides the pus organism, the common putrefactive germs which, working in the field prepared for them by the pus organism, add sapremia to the septicemia already existing. In either event the germs themselves are only the starting point, the seeds of the harm which the host suffers. It is only in rare instances that the bacteria in and of themselves directly harm the host, but in their growth, as the result of their life processes—their eating and drinking, we might say—they create and liberate, in the tissues of the host, a number of complex chemie substances, many of them poisonous to their host and all, at least in a degree, poisonous to themselves. Being poisonous to themselves it might be remarked, why interfere, let them stifle in their own excreta. Here the blood stream becomes an important factor. These substances acting under natural laws familiar to you all, pass readily and quickly by osmosis into the blood mass and thus not only influence the adjacent cells but those of remoter tissues, such as the heart muscle, brain, spinal cord and various nerve centers and ganglia, the integrity of which are absolutely essential to life.

The rational treatment then, of infected wounds must have as its ultimate object, 1, the prevention of bacterial growth; 2, prevention of osmosis of the ptomaines into the blood mass, commonly spoken of as absorption, and 3, such general treatment as shall counteract the pernicious effects of the ptomaines upon the vital tissues. In the past it has been attempted to secure the first results by the use in and about wounds of substances known or imagined to have a destructive or inhibitory action upon the growth of the bacteria. In the very nature of things this course could be but partially successful. Had it accomplished the desired results nothing more would have been necessary, but in point of fact, in the treatment of this class of cases in the past, the greatest dependence has been placed upon drainage and irrigation, which seek to limit or prevent ptomaine absorption. That these measures fail in a good proportion of cases, even when reinforced by stimulants and tonics, is attested by the number of deaths from infected wounds of fingers, hands, arms, feet and legs which occur in the practice of able surgeons; and the number of cases that drag on and on until, should death not occur, the patient is finally dismissed broken down in body and mind. It may seem that no one but an overconfident optimist would dare present a line of treatment with the claim that it would practically always succeed in such a dismal field, but after an experience embracing scores of cases extending over several years of hospital and private practice I come before you to-day to affirm in the most emphatic manner that continuous submersion, intelligently carried out, will in the vast majority of cases, save both the life and the limb. That submersion is a prompt and reliable measure in these cases is attested by the experience of every surgeon that has been induced to try it. How the result is produced I will attempt to explain by presenting the line of reasoning which first led to its use.

1. Many forms of bacteria will not develop at the temperature of an ordinary living room. Such as do so, develop less vigorously than at a higher temperature.

2. Many bacteria will not develop in a dilute watery medium.

3. Many have not the power of developing in strong healthy tissue but readily do so only after its vitality has been impaired by ptomaines.

4. The group of bacterial products collectively known as ptomaines are mostly crystalloids and all are capable of being influenced by osmosis.

5. Serum and substances dissolved in it, if not already within the blood vessel, will, as the result of a fundamental physical law, seek the "direction of least resistance," which in the case of a part that has been freely incised and submerged in a bland fluid is towards the fluid and away from the blood mass.

To these propositions personal experiment and experience have added the following:

6. Avoiding extremes, the temperature of the bath is immaterial.

7. The utility of the bath depends upon the fundamental physical properties of fluids rather than upon any "drug effects," hence pure water is the best fluid for submersion.

To give even the briefest synopsis of the cases treated by this method would be tedious and uninteresting, but I can not pass without relating the salient points of two histories that well illustrate points I wish particularly to impress upon the Fellows of this Academy.

An employe of our straw-board plant "infected" a slight wound upon the index finger of the left hand. The finger was industriously poulticed for two weeks so that at the end of that time, I found him with hand and forearm immensely swollen, temperature over 104, pulse 120, soft and easily compressible. Much of the time for a week he had been delirious but was at the time of my visit more rational. His physician, his friends and even he himself, considered his case hopeless. I had him conveyed at once to the hospital where, with the assistance of my friend and associate of the Academy, Dr. W. J. Fairfield, the brawny skin and subcutaneous tissues were freely incised and the arm submerged in plain water. Within four hours from the time I first saw him, I left him resting comfortably and painlessly with a temperature under 100. In two weeks he was back at work.

Early in 1891 I was called to take charge of a man that had sustained, nine days previously, a compound fracture (Pott's) and dislocation of the ankle. I found the wound full of maggots and the leg gangrenous to the knee. His temperature was 106 and pulse 130. The gangrene, of an emphysematous type, was extending with great rapidity and wishing to check its advance, improve the patient's general condition and gain time, I freely incised the necrosed tissues and placed the leg in a dilute boric acid bath. In six hours the patient was free from fever, resting well and able to take all sorts of nourishment. After keeping the leg in the bath for twenty-four hours, I amputated through discolored and emphysematous tissue, to save the knee joint, and got primary union.

In conclusion I beg to again formally submit these propositions.

1. Continuous submersion is harmless.

2. Continuous submersion will almost instantly limit infectious gangrene and control septicemia and sapremia.

3. Continuous submersion will quickly relieve the pain and discomfort of phlegmonous inflammation or cellulitis.

4. Continuous submersion will speedily reduce temperature and pulse and overcome the consequent depression of the patient's vital forces.

DISCUSSION.

DR. H. HATCH—I want to say to the Doctor that submersion is not a new thing. It is thirty years old. When I was a boy I was accustomed, in the neighborhood where I lived, to wait on the sick whenever they would give me an opportunity. At that time there was a doctor, who is now dead, by the name of Moses Wilson, living in the same neighborhood, a graduate of Harvard, who had a boy run over by a stock cutter. This was before the time of asepsis and antisepsis, but I remember distinctly the doctor had me there for three days with a pan with the boy's foot in water all the time. He kept me pouring fresh water in and letting it run out at the other end of the pan. The boy made a good recovery. A physician wanted to amputate the leg, but the boy's father would not allow it, saying that a boy without a leg had better be dead, and the doctor pursued this plan of treatment of submerging the leg in water constantly so as to keep it fresh and clean.

DR. WEBB J. KELLY—I wish to call attention to the fact that Dr. Merz, of Sandusky, Ohio, a fellow of this Academy, has published an extensive article upon this subject and in which he illustrates his method of submersion.

DR. L. E. LEMEN—These pictures are very familiar to me in one sense of the word. They remind me of the wards of my own hospital. For fifteen years or more I have practiced submersion in all infected wounds of the character mentioned. I have had three or four tin pans made, and have one in each surgical ward in my hospital. They are about twelve to fourteen inches deep and long enough to take a leg up to the knee. In pre-antiseptic days I used to apply bichlorid or some other solution, but for the last four or five years I have used nothing but simple water, and I am satisfied that I have saved many a limb by submersion. I recall to mind a recent case. A man working in one of our smelters wounded his wrist with a piece of slag, which is brittle and sharp. He ran the slag into the wrist through the ligaments and evidently severed the palmar arch. How long he stood letting cold water run on the wrist no one knew. He could not speak English. He finally fainted from loss of blood. Some good Samaritan, a physician visiting the hospital at the time, took a piece of waste material, white cotton, and bound the wrist up with a handkerchief, and when I saw the case the bleeding had ceased. He had packed the wound with some of this waste material. I dressed the wrist. I use considerable cement in my minor surgery, but I do not want to advocate it. A few days afterward I was called to see this man and found his temperature 105.5 F. He was delirious and his arm swollen to the shoulder fully as large as his leg. Realizing that his case was a serious one as he would not go to a hospital, I sent one of my assistants to the hospital to move one of my pans to the man's residence and had his wife change the water freely. The next morning the patient's temperature was normal. We could find no pus, but subsequently two incisions were made which let out a small amount of pus mixed with lymph. If the case had been allowed to go on two or three days longer the man would have had a cellulitis, which would have involved most of the tissue of the arm. Submersion is certainly rational treatment for these wounds.

DR. C. M. DANIELS—I wish to commend the paper. I have had ten years' experience with this method of treatment. In the hospital I have charge of in the city of Buffalo, my method is identically the one mentioned by Dr. Lemen. The pans are made of tin, and I find I could not get along in a hospital without resorting to this treatment, because there are many cases of infected wounds which come to us, and it is one of the best adjuncts to our armamentarium in the hospital.

DR. HODGES, closing the discussion—I am in no wise jealous of priority as is shown by the fact that I referred to its ancient use in the German hospitals, but considering that it was successfully used in St. Francis' Hospital in New York City, by Dr. Frank Hamilton, over twenty-three years ago, it is truly

remarkable that so valuable a method of treatment should so long have remained out of general surgical literature. That is one point that I want to bring out. I believe that each year a great many wounded people lose lives that might be saved by this procedure, and it was to bring this phase of the matter to the notice of the Fellows of the Academy that this paper was presented. I have preached submersion and recommended it for the last eight years and have made many converts. I certainly overlooked the reference Dr. Kelly made, but I have repeatedly gone over the *Index Medicus* since its foundation, as well as such other indices at my disposal, without finding other than the references I have given. This article is briefly referred to in that work on *material medica* which forms one of the volumes of Wood's Library.

If through the presentation or discussion of this paper a single member of this organization who has not previously done so, can be induced to employ submersion, I shall feel that my time has been well spent.

METHOD OF OBTAINING THE BEST POSSIBLE ASEPTIC CONDITION DURING OPERATIONS DONE AT PLACES OTHER THAN HOSPITALS.

Read at the Second Annual Meeting of the American Academy of Railway Surgeons held at Chicago, Ill., Sept. 25-27, 1895.

BY J. F. REGER, M.D.

SURGEON R. & O. RY., LITTLETON, W. VA.

Pregnant with glory as are the annals of surgery from its earliest history to the middle of the nineteenth century, illuminated as it has been through the darkness of its endless struggles by the wisdom of such men as Hippocrates, Harvey, Jenner and the two Hunters in the old world, and Physic, Mott, Morton and Gross of the new, it was left to the closing years of this century to furnish such a revolution in surgery as was never dreamed of by its most brilliant and ambitious votaries, as it was thought and taught by the most eminent authorities that ulcerating stumps, sloughing flaps, and discharging sinuses, excessive rises in temperature, gangrene, etc., were due entirely to vicious conditions of the system, humors, imperfect ventilation and poisons that were inhaled; when cleanliness was urged it was as much for cosmetic reasons as any other. When Sir Joseph Lister startled the medical world with the declaration that wounds purified or made aseptic by the use of antiseptics or germicides which destroyed microorganisms or prevented their entrance, or both, and were well drained and covered with dressings containing antiseptics and impervious to the air, would almost always, if not invariably, heal by primary intention with but little rise in temperature and with but little, if any, danger of sepsis or gangrene, he met with a storm of opposition and derision, as did Jenner when he announced that vaccination would stay the progress of smallpox, and as did Morton when he announced that ether would obtund all pain during the progress of a surgical operation. Notwithstanding all opposition the proofs were so indisputable that within a remarkably short period Listerism became an accepted fact, errors and all. The grand results obtained from operations everywhere, after his methods, were ascribed to the beneficent effects of the antiseptics used, more than to the aseptic condition obtained by the use of them. But the road once marked out, it was not long until there were numerous able reviewers each accepting the principle, but each striving to improve the methods. Operations done strictly after Lister's methods were done under a continuous spray of strong carbolic acid solutions

and the frequent sponging of the open wound with the same solutions. Reports were soon published of patients who had been dangerously poisoned by the absorption of antiseptic solutions, and methods were sought by which to make instruments, wounds, and the dressings aseptic without the use of antiseptic solutions in the wound where the parts were not already affected. This is the great desideratum we hope for. The hospitals practically have it, but what of the surgeon who does 90 per cent. more operations outside of hospital than in them, who has to deal with floors, ceilings, walls and beds which are decidedly far from clean. I think that this is a wide and useful field for discussion—a field in which there is yet much to be developed, there being, so far as I have seen, no special lines or rules laid down in regard to such operations. This is why I offer to the Academy for their criticism the method I have used with slight variation for several years. I have three satchels, one large one containing instruments, basins for solutions for sterilizing the hands and a pan for sterilizing instruments by boiling. The other two satchels are of medium size, one containing sterilized dressings, ligatures, sutures, etc., the other operating gown, aprons, towels, table covers and sheets all sterilized with steam. I keep my satchel always packed ready for instant transportation and use. I wrap my dressing gowns, sheets, ligatures, towels and table cover in pieces of canton flannel, securely pinned and keep the packages in a steam sterilizer two hours. They are never opened until the instant they are to be used. Having arrived at the house where the operation is to be done I first have the floor of the operating room well scrubbed with boiling water, some scalded jars filled with boiling water, covered with pieces of canton flannel and set aside to cool; then while some of the bystanders are scrubbing the table to be used as an operating table and a stand or two for holding instruments, I select the instruments to be used including needles and place them in my pan with a weak solution of bi-carbonate or soda and set them to boiling. I then turn my attention to preparing the patient. I have his clothing changed and have him well washed with soap and water; I then have the field of operation thoroughly scrubbed and shaved. After shaving I scrub the parts with soap suds and solution of bi-chlorid 1 to 1,000 and rinse with alcohol; then wrap the parts with a sterilized towel wrung out of a solution of bi-chlorid 1 to 1,000 until ready to operate. I then select the place in the room having the best light and immediately over the spot where the table is to stand, I have a large sterilized sheet tacked by the four corners to the ceiling; I then place the table on which is a folded quilt freshly washed, if possible to obtain one, and over all spread a sterilized sheet. My assistant after thoroughly sterilizing his hands by first scrubbing them with soap and water, next with a strong solution of permanganate of potash, then with a saturated solution of oxalic acid and rinsing with alcohol, administers the anesthetic, while myself and attendants I have chosen, sterilize our hands and put on our gowns and aprons. The stand is now covered with a sterilized stand-cover upon which is laid the unopened packages of dressings, some sterilized towels and the sterilized instruments still in the boiling solution. The patient now anesthetized is removed to the table and covered with a sterilized sheet. If it be an amputation, the injured or deceased part is wrapped in a sterilized towel wrung out of 1 to 1,000 bi-chlorid

solution, the limb is elevated and stroked toward the trunk, and the Esmarch bandage applied. The needles having been threaded and placed in a vessel containing a boiling solution of carbolic acid 10 per cent., the operation is proceeded with in the usual manner, except that I do not use sponges or irrigate or wash the wound inside. I simply sponge clean and dry with pieces of sterilized absorbent gauze. After the vessels are tied and the ligatures cut off close to the knot, I pack the wound with gauze while I place the stitches; I then withdraw the gauze and bring the edges neatly into opposition and tie. If the flaps are sound I do not use drainage. After dusting with iodoform I cover the approximated edges of the wound with a strip of iodoform gauze, then a few layers of absorbent cotton and a roller bandage firmly applied finishes the dressing. The patient is then placed in a clean bed and the dressing not removed until the eighth or ninth day. The stitches are then removed and the wound dressed as before. I have done a number of operations as described, among them a double synchronous amputation of both legs below the knee. All have healed rapidly and without suppuration, and it is seldom that I apply more than three dressings.

Gentlemen, I thank you for your attention and if my paper evoke discussion which will develop something new and useful in this field it will have served its purpose well.

DISCUSSION.

DR. HENRY W. COE—In the couple of weeks I spent about the hospitals in Chicago, I found that the permanganate of potash solution was quite frequently used at one time, but I notice now that its use has largely passed away.

DR. WM. T. DALBY—The paper read is one of considerable importance, bearing as it does on a topic of this character. As Dr. Coe has just remarked, the permanganate of potash solution has largely died out, and the promiscuous use of the bichlorid solution is not near so frequent as it has been. In cases where we operate outside of hospitals, particularly in emergency cases, it is not only handy but more convenient for the railway surgeon to carry the things mentioned by the Doctor. Boiled water is an aseptic solution without anything being added to it, and I do not know of anything better. I do not know whether it is best or not sometimes to add to our solutions bichlorid of mercury, carbolic acid, or any of the other agents. The subject of aseptic surgery and aseptic conditions, to be practiced by the railway surgeon in conditions of emergency, is certainly entitled to careful consideration, for we may be called upon at any time to treat accidental injuries where we can not have things as we want them, and we must make the best of the existing conditions and circumstances. The Doctor's paper is a good one, and he has written on a timely subject.

DR. L. E. LEMEN—I was much pleased with the paper, and in regard to antiseptics, I presume it is simply the principle of making assurance doubly sure. Aseptic surgery is what we should practice up to the point when any wound becomes septic. Then, antiseptics come in. I have not for over two years in any of my surgery, abdominal or otherwise, used anything but boiled water and neutral salt solution, and my results have been good. In a case upon which I operated not long ago, an amputation in the upper third of the thigh, I used neither a sponge nor irrigator, simply pouring my salt solution over the stump, and doing it up. On the eleventh day I changed the dressing, and on the thirteenth day the patient was declared well. I did not use an antiseptic during the whole time. I have not for a long time used iodoform, and I will tell you why. A few years ago I used iodoform in my dressings very thickly, and instead

of riding home in my carriage I took a street car. Sitting at the opposite end were two well dressed ladies, and one remarked to the other: "He has not taken a bath for a month." Aseptic surgery is what we desire to practice until such time as necessity requires antiseptic surgery.

DR. F. J. HODGES—In the class of cases we have to deal with in railway practice the environment of the patient and the surroundings are of the greatest importance in considering what is absolutely necessary to do in any given case. In an open country, where the railway surgeon is often called upon to practice his vocation, very little attention to these details will secure perfect surgical results, and cases have come to the notice of all of you in which the most important and careful operations have been performed with seemingly no attention having been paid to asepsis, and yet typical results have followed. I do not say this in a way to disparage the practice of aseptic surgery, or that aseptic precautions should not be taken, but if the loss of time is too great it is better to give the patient the advantage of the operation with such surroundings and means as you can secure, particularly in very closely and thickly populated sections of the country.

DR. C. M. DANIELS—I think the subject is one to which we ought to pay a great deal of attention. It is simply the final closing up of the wound, especially in amputations, and it means more attention than the primary preparation. The Doctor has very well outlined the method of preparing the room, the instruments and the patient, but I think previous to the application of the dressings that the last thing done in the way of thoroughly closing the stump is the most important of all, so far as the avoidance of sepsis is concerned. I quite thoroughly agree with Dr. Lemen in regard to the use of chemicals upon open surfaces, and I have abandoned their use. I do not believe it is necessary to use a chemical, not even bichlorid, iodoform, or anything else when you can secure thoroughly sterilized water, water that has been boiled in a clean receptacle with which the wound may be flushed at the last moment. I have a stream of water pouring into the wound the last thing before applying the dressing, when everything is aseptized. We close up the stump with such means as we always have at hand. Boiled water in a clean receptacle is the most important thing in the whole operation so far as avoiding sepsis is concerned.

DR. L. E. LEMEN—I would like to call attention to the use of the irrigator. I have found since I have abandoned the use of the irrigator that I have union by first intention a great deal oftener—in fact, it is exceptional that I do not have it. At an elevation of four feet, the water coming through the ordinary syringe, striking the cut surfaces of our muscles, the irrigator does far more damage than we have any idea of, and instead of using it I use a large mouthed pitcher, gently pouring from it over all the surface. I do not daub my wound with sponges, lint, or anything else. With proper hemostatic forceps bleeding can be easily controlled. I rarely use them in major operations. I know where the location of my bleeding points is, and I ligate them before I remove my tourniquet. I have had much better results since I have abandoned the old fashioned fountain syringe, as I believe that we do violence to the cut muscular fiber by forcibly ejecting water against it.

DR. C. M. DANIELS—That is my method of irrigating wounds. In amputations of the thigh, I turn the thigh up and merely flush it out, instead of making pressure.

DR. WM. T. DALBY—While we are on the subject of antiseptics I would like to ask whether or not any member has used acetanilid in dressing surgical wounds.

DR. ELISHA GRISWOLD—At the meeting of the AMERICAN MEDICAL ASSOCIATION, held in San Francisco last year, I heard a paper read by an assistant surgeon in the Army, whose name I can not at present recall, on acetanilid as a local application, or as a substitute for iodoform, and which he recom-

mended very highly. Shortly after the meeting I had occasion to dress a contused wound of the hand with it. The patient was a workman in a blast furnace. I washed the wound carefully at first in order to remove all of the septic matter, and I thought I had gotten it all out of the wound. I then sprinkled the acetanilid over it according to the directions given by the gentleman referred to. The result in that case was the development of an erysipelatous inflammation. I converted the wound into an ugly condition, so that it took the patient three or four times as long to get well as it would have done if the wound had been dressed with gauze, iodoform, or subcarbonate of bismuth. The latter has no odor and is as good as iodoform in its results. After adopting the method suggested by this gentleman I was discouraged, and I have not since applied it on a wound. I have tried it on small wounds, and I find that it acts as an irritant.

A MEMBER—Was the wound very much contused?

DR. GRISWOLD—It was not very much contused. It was a lacerated wound on the back of the hand and not a very large one, but an erysipelatous inflammation developed over the back of the hand as a result of the use of the acetanilid. After using it several times subsequently in smaller wounds, I thought the doctor who recommended it had made a mistake.

DR. REGER (closing the discussion)—I believe there is no difference between myself and my critics. I have not for several years applied antiseptics to the inside of a wound, as the paper alleges. A man is brought to you, we will say, with his limbs crushed and covered with cinders, dirt and grease, and the only place where I would use an antiseptic is in preparing the part for amputation. In crushed wounds you will always find to a greater or less distance from the wound that the tissues are entirely devitalized, and consequently with a few exceptions the surgeon can make his amputation through sound tissue. I do not irrigate. I use sterilized gauze sponges and if there is any oozing of blood after the surface is closed it must be aseptic and must absorb harmlessly. I use all my antiseptics prior to the operation. I take everything along with me to make my operation as nearly aseptic as I can. The sheet is for the purpose of preventing any particle from falling into the wound.

VAGINAL LIGATION OF THE BROAD LIGAMENTS FOR FIBROIDS OF THE UTERUS AND OTHER MINOR SURGICAL TREATMENT.

BY FRANKLIN H. MARTIN, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL, SURGEON TO WOMAN'S HOSPITAL, CHICAGO.

Vaginal ligation of the contents of the base of the broad ligaments, for the cure of fibroids of the uterus, was devised and performed by me as a new and original operation Nov. 15, 1892, and was described and published in the April number of the *American Journal of Obstetrics* in 1893. In the January number of the *American Journal of Obstetrics*, 1894, I reported six cases treated by the new operation.

The operation as originally described by me is as follows: The ligation of more or less of the broad ligament of the uterus, with its vessels and nerves, the extent of the ligation depending upon the result sought, from a simple ligation of the base of the ligament, including the uterine arteries and branches of both sides without opening the peritoneum to a complete ligation of the ligament of one side, including both uterine and ovarian arteries, with partial ligation of the opposite ligament without opening the peritoneal cavity, if possible, but by doing so if necessary.

The results sought in the operation are, first to check uterine hemorrhages by cutting off blood channels, and secondly to produce atrophy of the fibroid by, 1, depriving it of nourishment through the blood vessels and, 2, by changing the nutrition of the uterus by interfering with its nerve supply.

Immediately after publishing my first article on this operation there were two claimants for priority; Dr. Walter B. Dorsett, of St. Louis, and Prof. S. Gottschalk, of Berlin, Germany. Dr. Dorsett, in a letter to the *American Journal of Obstetrics*, claimed that he had suggested a similar procedure to my operation in an article he published in the *St. Louis Courier of Medicine* in 1890, the article bearing title of "A Case of Atrophy of the Female Genitalia following Pregnancy and remarks." In this article he made the following observation: "I believe that in the treatment of uterine fibroid . . . to ligate the uterine artery would not be an unscientific procedure. On the contrary the more I have thought of it the more I am inclined to believe that it would be the most certain mode of treatment." Dr. Dorsett, while advancing the theory, had not at that time carried it out on a living woman.

Prof. Gottschalk based his claim of priority on an article read by him at the Brussels Congress, Sept. 16, 1892, with the following title: "Die Histogenese und Aetiologie der Uterusmyome." In the latter paragraphs of this article he casually suggested ligation of the uterine arteries and stated that he had performed the operation twice. This is what he said: "The bilateral ligation of the uterine arteries appears to be the therapeutic measure in this regard for the earliest incipient stages of myoma. This offers no difficulties in its technique; it is easily performed in a few minutes. . . I have already performed this ligation in two cases in which I was able to early diagnose the development of multiple myoma with best results."

Thus these two men both suggested tying the uterine arteries for the cure of fibroids and at least one of them (Gottschalk) performed the operation twice before I described my operation. This would definitely decide the question of priority in their favor if the operation they suggested was identical with mine. Their operation is not identical in theory, in execution, or in description with mine, and therefore their claim of priority for my operation can not be substantiated.

The operation suggested by these men simply includes the ligating of the uterine artery from the vagina, while, 1, I ligate in all cases, the whole base of the broad ligament, in order, *a*, to occlude not only the main channel of the uterine artery, but all collateral branches; *b*, in order to destroy the function of the nerves as well as the arteries of nutrition; *c*, in order to diminish nerve reflexes. 2. I include, in desperate cases, not only the base of the broad ligament with the uterine artery and branches in my ligatures, but when practicable ligate high enough on one side to take in the ovarian artery. 3. I advise accomplishing this result, if possible, without opening the peritoneal cavity, but by doing so, if necessary.

TECHNIQUE OF OPERATION.

The preparation of a patient for vaginal ligation of the broad ligaments of the uterus should be similar to that demanded for vaginal hysterectomy, as

described in my article last week. Ether is used as an anesthetic and the patient is placed on the operating table in the exaggerated lithotomy position with buttocks brought to end of the table, with an assistant on either side to support the limbs and hold the vaginal retractors. A broad, short vaginal retractor above and below exposes the cervix, which is trans-fixed with a strong silk ligature to be employed in handling the uterus. The uterine canal is dilated and the uterine cavity curetted with a dull curette and thoroughly irrigated with 1:1000 bichlorid solution and then loosely packed with iodoform gauze. This procedure cleans the uterus and makes it impossible for the vaginal wounds to become infected by a septic uterine discharge. The uterus is now drawn down in order to put the broad ligaments on the stretch and then drawn to the right side so as to expose the left vaginal vault. The mucous membrane of the vagina at the utero-vaginal fold on the left side is then caught with a tenaculum and incised with a pair of curved scissors. One blade is allowed to enter beneath

trunk of the uterine artery and occasionally several branches. The curved pedicle needle is then passed, armed with No. 10 silk, strong pyoktaninized catgut or kangaroo tendon, and guided by the index finger of the left hand (Fig. 4) is made to penetrate through the broad ligament. The ligature is drawn through, the needle removed and the base of the broad ligament is thoroughly ligated at a distance of one inch or more from the uterus. The ligature is cut short, leaving it buried in the tissues of the ligament. The other broad ligament is treated in the same manner; the vagina is well sterilized with bichlorid solution and the vaginal incision accurately approximated with fine antiseptic catgut so as to completely bury the broad ligament ligatures (Fig. 5). The handling string is now removed from the cervix, and the end of the gauze strip packed in the uterus is tied to another strip and the vagina is filled loosely with a gauze drain.

The after treatment of these cases is very simple. The vaginal and uterine gauze is removed the second

FIGURE 1.

the mucous membrane and a curved incision one and one-half to two inches long is made over the broad ligament and at right angles to it (Fig. 1). By means of the index fingers of the two hands the operator now separates the vaginal tissue from the broad ligament and carefully separates the broad ligament in front from the bladder for a height of two inches and laterally for nearly the same distance (Fig. 2). The bladder should be carefully separated in this way in order to avoid the danger of wounding the organ, and by pushing the separation laterally the ureter is forced out of danger. One then carefully separates the broad ligament posteriorly to the same height as in front, without, if possible, penetrating the peritoneum. Now, by passing one finger behind the other in front, the whole base of the broad ligament, representing two-thirds of its bulk, can be grasped (Fig. 3) for a distance of an inch to an inch and a half from the uterus. In this grasp one can easily feel the throb of the main

FIGURE 2.

FIGURE 3.

or third day, and twice a day thereafter a bichlorid vaginal douche 1:2000 followed by plain douche are given. Figure 6 shows the position of ligatures when only the base of the broad ligament is ligated.

SELECTION OF CASES.

Interstitial fibroids of the uterus of moderate size are the cases in which the best results will be obtained by this operation. Subperitoneal fibroids springing from the fundus of the uterus especially would scarcely be benefited to any great extent by depriving the lower part of the uterus of its nourishment. Neither would one expect to obtain any lasting benefit from this operation in cases of pedunculated submucous fibroids. On the other hand, in true interstitial growths depending upon the whole uterus for their nourishment, cases where the tumor is the uterus, and these represent 75 per cent. of all fibroids of the uterus, wherever it is possible to tie the base of

the broad ligament from the vagina, this operation may be expected to accomplish prompt and decided relief of symptoms and a rapid reduction of the tumor. The cases in which the most satisfactory results must be expected are incipient or small fibroids of the interstitial variety which show themselves late in the menstrual life. Here, we have a uterus which is small enough so that it has not risen above the brim of the pelvis, one which can be easily reached from the vagina so that its broad ligaments are accessible from below. Such a fibroid, too, from the age of the patient will reach a state of quiescence as soon as the menopause is established. In such cases, then, a major operation is particularly undesirable, because it is not imperatively demanded and because of a reasonable chance of relief at the approaching change; on the other hand the symptoms (with severe hemorrhage usually as the principal one) are such that immediate relief is earnestly sought, if one can be reasonably certain of obtaining it without submitting to a dangerous and radical procedure. These are ideal cases for this operation.

Another class of cases in which this operation has been employed with gratifying success and in which it will probably find favor with the most radical operators, are those of continuous and profuse hemorrhage in which the desperateness of the drain is such

FIGURE 4.

that the patients are depleted to such a degree, that no radical procedure can be thought of, until a minor operative procedure has checked blood waste and recuperation is accomplished. My fourth and sixth cases were like the above. In the fourth case hemorrhage was very profuse and the patient was completely exsanguinated and so weak that she had not been out of bed for several months. Some time before I determined to submit her to my operation an attempt had been made to remove the appendages, or, if possible, when the laparotomy was in progress, the uterus. From complicated adhesions and the weakness of the subject neither operation was possible after the abdomen had been opened. The tumor was large and the elevation of the uterus in consequence was great, and it was with the utmost difficulty with the aid of the most competent assistants, that I finally succeeded in ligating thoroughly the base of each broad ligament. Both ligaments contained several arteries, some of them as large as the normal radial artery. They were all tied in mass. Hemorrhage stopped from the instant of tying the last ligature and it has never recurred. It has now been over three years since I operated on this case. The uterus has reduced until it is but slightly larger than normal. The woman (I examined her but a few months ago) is perfectly well.

She has a slight menstrual flow each month, and is free from pain.

Case six was of a severe hemorrhagic nature in a typical interstitial fibroid of three by five inches in diameter. The woman was too weak and depleted for a radical operation. I did my operation on her and the result was marvelous. In three months' time she had recuperated so that any radical operation might have been done without danger.

Dr. Humiston, of Cleveland, reported to me a case in which he used my operation as a procedure of last resort, in a patient nearly moribund from hemorrhage. She was so weak that he only attempted ligation on one side. The woman stopped bleeding instantly and eventually recovered. Hence, the operation may with propriety be employed as a rational temporary expedient in desperate cases of whatever variety, where uterine blood loss is conspicuous.

CASES.

In selecting cases for this operation I have been very careful. In the majority of them I have operated on, there seemed no alternative. All were desperate ones, like cases 1, 2, 3, 6 and 8, or they would not submit to a more radical procedure, and milder means, as electricity, ergot, etc., would not accomplish satisfactory results. I have been more conservative in adopting the operation, I am afraid, than the results in the few cases I have operated on would justify. One reason for not adopting the operation in a larger number of cases is that I wished first to learn of the remote results. It is now over three years since my first operation and most of the operations which I have performed were during the first year. I have,

FIGURE 5.

therefore, a three years' history to analyze in the majority of my cases. In the following report there are no instances in which, at least, a year has not elapsed since the operation.

Case 1. This was an interstitial fibroid in a maiden lady 36 years old, in size extending above the umbilicus. The hemorrhage was exhaustive and the patient greatly reduced in consequence. Her heart was hypertrophied and her condition was such that no surgeon with a proper care for his statistics or his patient's life would have ventured a hysterectomy. She was operated on by my operation Nov. 15, 1892. The hemorrhage decreased about one-half for several months after the operation. The tumor in the first four months materially decreased in size. In May, 1894, the hemorrhage is reported much modified, and no longer a source of alarm. The patient at that date considered her condition greatly improved, hemorrhage cured, tumor materially reduced and pressure symptoms subsided. March 12, 1896, four years and three months after the operation the patient reports herself well. The original fullness produced by the tumor she can no longer feel. No pain. The last flowing of any consequence was November, 1894. Since then the flow has been very slight until last July, when it practically ceased. "I have color in my lips and cheeks. I walk two miles or more every day," she writes. This report is certainly very gratifying.

Case 2. The second case was a married woman 40 years of age who had been under electrical treatment for a hemorrhagic myofibroma of the uterus. The galvanism decreased the size of the growth but did not materially lessen the exhaustive hemorrhage. The tumor was of the interstitial variety and

the uterus appeared the size of a three months' pregnant uterus. When the patient entered the Woman's Hospital for operation December, 1892, she had been having almost continuous hemorrhage for several months. Upon exposing the uterus with the retractors at the time of the operation, the cervix was large, blue and vascular. As the vagina was large the operation was very easily executed. The ligature on the left side included fully two inches in width of the broad ligament at a distance of at least an inch from the uterus. When I tightened this first ligature one of the spectators, a well known gynecologist, called my attention to the fact that the cervix had perceptibly paled in appearance. The broad ligament was easily exposed on the right side, and fully as much of it ligated as on the left. If there had been any doubt of the procedure affecting the vascularity of the uterus, it vanished when the second ligature was tied. The cervix immediately paled until it was nearly as white as a piece of cartilage.

The covering of the broad ligament was so loosely attached in this case that I could easily feel the main channel of the ovarian artery, and it would have been an easy matter to have included it in the ligature.

After over three years I can promise this case a perfect cure. The uterus has reduced to normal size. The hemorrhage has ceased completely. All pain has disappeared. A slight menstruation, normal in quantity, occurs each month. The patient's health has improved so that from a state of almost complete invalidism she is transformed into to a strong healthy

FIGURE 6.

woman. The improvement has been progressive from the day of the operation. I have seen this case within the month (March 1896).

Case 3.—This patient was operated on in January, 1893. She had an incipient interstitial fibroid of two years' standing which was profusely hemorrhagic in nature. I tied the base of both broad ligaments including the uterine arteries and their branches. The relief was immediate. The menstruation for the next four months was scanty. The patient gained in health and strength rapidly. The tumor, which was the size of a four months' pregnancy at the time of the operation decreased markedly in size within three months. Four months after the operation I lost track of this case, as she lived in a distant State and neglected to keep me posted. Her last letter gave a report of perfect health.

Case 4.—This patient had a large, bleeding fibroid filling the pelvis, which extended to the umbilicus. The uterus and appendages were firmly adherent and immovable. Laparotomy had been attempted on the case, with the object of removing the appendages or the tumor. The abdomen was opened, but the adhesions and unusual complications rendered it impossible to remove the tumor or even accomplish the oblation of the appendages. The patient was so unusually reduced from loss of blood at the time of my operation that she had not been able to be out of bed for three months.

I operated on the patient in January, 1893, at the Post-Graduate Medical School of Chicago. The operation was accomplished with great difficulty because of the large size and immovability of the uterus. Finally, however, after consum-

ing more than an hour in time I succeeded in ligating thoroughly the two broad ligaments well above the uterine arteries and their branches.

In June following I made the following report on the case: "The flowing ceased immediately and the patient was relieved of her drain for over two weeks. She then had a few days' flowing, which resembled an ordinary menstruation. She has rapidly and steadily improved since that time. She has menstruated regularly but scantily, and without pain. She can at this time (June, 1893), five months after the operation, attend to her duties as a housewife, and considers herself cured. The tumor has become reduced in size until it is no longer noticeable as a deformity, and so that the patient herself is no longer conscious of its presence."

Since the foregoing report was written in June, I have seen this patient several times, the last time within the month. The patient was then examined by several physicians, one or two of whom on independent examinations, failed to notice any abnormal enlargement. The uterus is still somewhat larger than normal, but is not more than three or four inches in diameter, while the testimony of at least three experienced diagnosticians will bear me out in the estimate that its former diameters were not less than four and a half by eight inches. The patient is in good health now, Jan. 1, 1895; menstruation is regular but scanty, and she is free from pain. The patient, so far as I know, has remained well.

Case 5.—This case was a woman with an interstitial fibroid about three by five inches. She was about 30 years of age, and the growth had been noticed for three years. Her principle symptoms were profuse menorrhagia with severe menstrual pain. The case was referred to me by Dr. F. H. Greer, of Columbus, Neb. I did my operation on the woman Jan. 8, 1893. She had a little subsequent temperature, and one month after the operation the ligature sloughed from the left broad ligament. Four months after the operation Dr. Greer reports the woman well. "Menstruation scanty, no pain. Fibroid diminished in size until the uterus is about normal. Patient claims that she is cured." This report was made in June, 1893. I have been unable to get any history subsequent to that date.

Case 6.—This was the wife of a physician of more than ordinary ability and reputation. The patient was about 36 years of age, slightly above the average height, with well-proportioned frame, but poor in flesh, with a skin blanched and a body almost exsanguinated. The uterus was about the size of a three months' gravid uterus. The tumor was uniform and evidently interstitial. The uterus was in normal position. The cervix was nearly two inches in diameter, the os patulous.

The history of the growth dated back, undoubtedly, several years. The patient had borne no children. The menstruation had for nearly two years increased in quantity and duration, until now, while coming with absolute regularity, it lasted fifteen days, and that in spite of vaginal and uterine tampons, the recumbent position, ergot, hydrastis and the rest. She flowed each month until she was completely exhausted, scarcely recovering in the next thirteen days sufficiently so that she could assume the upright position without fainting. Accompanying this unusual discharge was uterine pain, which in its severity brought the patient to the point of unconsciousness. During the four days in which the woman could drag herself around in the latter part of each intermenstrual period she did so with the greatest discomfort on account of the pressure and neuralgic pains of the pelvis. Upon examination of the broad ligament from the vagina the finger could detect on either side the large, pulsating artery as it fed the tumor. The latter was movable, the appendages apparently normal, the broad ligaments accessible. In fine, here was an ideally typical case—a hemorrhagic fibroid of the uterus, a bed-ridden patient, an authentic diagnosis, an unusually interested physician to carefully watch and estimate the result, and one who enthusiastically demanded a trial of the new operation. Under the circumstances it seemed to me that much depended upon this case, as though the fate of this operation must necessarily be more than usually linked with this particular patient.

I operated on this case Aug. 2, 1894, at the Chicago Hospital, with Dr. Robert Dodds and Dr. Oksschet as assistants. The left broad ligament was carefully dissected from the peritoneal covering behind, and from the bladder in front, until fully two-thirds of it could be grasped by placing one finger behind it and another finger or instrument in front of it. When grasped in this manner several beating branches of the uterine

artery, together with the main artery itself could be detected. This entire mass was then ligated in two sections with No. 12 braided silk, the silk cut short, the parts irrigated and the vaginal wound closed with catgut. After treating the opposite side in the same manner, the vagina was cleansed and loosely packed with iodoform gauze. When the operation was finished the throbbing arteries, which could be distinctly felt before, could no longer be found. The cervix, which was large and purple previous to the operation, became pale and cartilaginous in appearance as soon as the ligaments were secured.

The patient remained in the hospital three weeks. The first menstruation was due the day following the operation. It began the next morning, but was so slight and painless that the patient would not believe that it was her menstruation until several days had elapsed and no other flow appeared. It lasted about three days and was barely perceptible; absolutely no pain. The after treatment consisted in vaginal douches after removing the gauze, light diet and the recumbent position for two weeks.

August 30, the second menstruation reappeared: there was a little of the old pain, but not sufficient to require anodyne of any kind: the flow was half the usual amount and lasted six days. September 28, the third menstruation appeared: the amount was normal in quantity, lasting but four days; the pain was slight. October 26, the fourth menstruation appeared: the amount normal in quantity, lasting but four days: the pain was slight. The patient was seen and examined by me just before the last menstruation. She had gained several pounds in flesh, her cheeks and lips were red and she was a picture of health and robustness. Her feelings were in accord with her appearance, as she enthusiastically assured me that she felt perfectly well. On examination I found the uterus was reduced in size. It was little, if any, larger than normal. Its bulk had decreased one-half. The cervix was small and normal. No arterial pulsation could be felt in either broad ligament or around the vault of the vagina.

The next report I received was in January, 1894: "I have to report," the husband says, "that Mrs. X. menstruated from December 19 to 24. That the amount was above the same as before, *i. e.*, slightly above the normal. Pain rather excessive for two days (possibly due to rheumatism and neuralgia). After flow had ceased I examined and found ligature in vagina and also small sinous opening to left side of cervix. Since then there has been slight discharge from same. She had been suffering some pain at that point, no pain since ligature came away." He adds enthusiastically: "Taken all in all, the result so far is a grand success." Jan. 17, 1894, he writes: "Mrs. X. is up to-day (the fifth day) after the easiest menstruation she has had in her life; pain moderate and on one day. This in face of the right side still discharging. In the next two months I expect to have a well woman. The uterus is now practically normal."

I have lost track of this patient entirely, and I regret that I am unable to complete so interesting a history. If the husband of this patient should read this report I hope that he will communicate with me.

Case 7. Mrs. S., Denver, Colo., aged 35, uterus about double the normal proportions, containing two or more centers of development and an extremely hemorrhagic tendency, was the seventh case operated on. The case had been treated unsuccessfully by curettement, electricity and the ordinary remedies for checking uterine hemorrhages. The uterus was retroverted but free from adhesions. The patient was prepared carefully, and at the Woman's Hospital, on Nov. 11, 1893, I ligated the base of both broad ligaments, and shortened the round liga-

ments. The uterus was drawn well down, and each broad ligament, after incising the mucous membrane covering them in the vault of the vagina, was dissected free from the bladder and rectal attachments and then ligated with two strong ligatures. These ligatures were placed high enough to include the uterine artery, all its branches, and all of the contents of the base of each broad ligament. The ligatures were cut short after they were tied, the mucous membrane of the vagina was reunited with a running catgut ligature, and the vagina packed with iodoform gauze. The round ligaments were then shortened and the uterus left in a position of anteversion. Three days later the gauze was removed from the vagina, an antiseptic douche was given and a Smith-Hodge pessary was inserted. The antiseptic douches were then continued daily. The first menstruation was due four days after the operation. It did not appear. The second menstruation also failed to appear, notwithstanding the fact that menstruation had ordinarily been exhaustive.

One of the wounds caused in the operation for shortening the round ligament suppurred, and obliged the patient to remain in the hospital until the latter part of January. Dizziness was complained of about the time when the menstruation was due. This symptom continued with different degrees of severity for some time, gradually disappearing. February 13, three months after the operation, the first flow appeared. The patient writes: "First menstruation came on the 13th of this month, without pain, but quite profuse for first two days. Since then has continued, including to-day (the 18th). Discharge light."

March 19, 1894, the patient reports: "Am feeling fairly well this month. Had pain in back with last menstruation, which commenced March 13. First three days quite profuse; last four days very little. No dizziness this month." April 18, she writes: "Menstruation came on four days in advance of schedule time; continued one week. Am in fairly good health."

December 14, 1895, two years after the operation, the husband writes that his wife suffers considerably with vertigo, especially severe immediately before menstruation. "The operation performed by you has in a measure been successful, as the menstrual discharge is much less than before the operation and the womb is in much better position."

March 26, 1896, the husband writes: "Her menstruation is not profuse and she has less pain; her general health about the same" (as in her last letter). "I think the riding of the bicycle improves her general health and strengthens her in those parts wherein she is weak."

Case 8. — Mrs. Z., Muscatine, Iowa. About 35 years of age. No children. Multiple fibroid of the uterus approximating in size a four months' pregnancy. Hemorrhage profuse, followed for a week by excruciating pain. Patient became extremely exsanguinated at each menstrual period. Frequently the flowing would last for two weeks. The uterus had been curetted. Electricity failed to control the hemorrhage and only partially modified the pain. The irregularity of the uterine canal undoubtedly accounted for the failure of the electricity. Nov. 28, 1893, the patient submitted to my operation for ligation of the broad ligament. The tumor was developed more to the left side into the left broad ligament. I succeeded in separating the broad ligament for a height of two inches. On the right side a large double ligature was employed, while on the left side first a double and finally a second one higher and farther away from the uterus was applied. The ligatures were cut short, the vaginal vault closed with catgut and the vagina packed with iodoform drain. The first menstruation was due three days following the operation. A slight watery discharge occurred instead of blood. Two days following the operation the patient complained of pain similar to that which ordinarily occurred after menstruation. Feb. 1, 1894, the patient's husband writes: "She commenced her menstruation January 25, and it was continued until to-day, February 1, one day less than last time. Had one day of some pain; not bad. She is getting stronger and can get around the house without being very tired, although

she has not yet ventured out." February 26, the report is: "Mrs. Z. was sick this time six days, the same as last time. Had considerable pain two days which was very severe, the same as she complained of before the operation. She is getting along very nicely. She is now able to go out, and takes a walk every day." March 26, the husband writes: "I am ready to make another report, but not as good a one as I would like. Mrs. Z. was sick on time and the flow was very little compared to what it has been, lasting but three days, but she had a great deal of pain—some before she was sick, and it was quite bad for two days after the menstruation. . . . Everything seems to be working very well if she could only get rid of that pain." April, menstruation still decreasing in quantity; the pain decreasing. "There was one day of pain," the husband writes, "and the flow amounted to but very little." May 6, he writes: "Mrs. Z. has been feeling splendidly all this last month. Last week was her time to be sick again. The flow did not amount to anything, just enough to show. . . . In regard to her general health, it is excellent. Eats well, sleeps well and goes out every day the same as other women. Has gained her natural amount of flesh and a little more." I examined the patient May 19. The uterus was reduced in size one-half. Patient in perfect health.

March 13, 1896, two years and four months after this woman's operation, I received the following report from this patient: "Since the operation I have gained twenty pounds or a little more up to date. My menstruation period is about one-half the time and amount it was before the operation. The pain is very much less than I had before the operation, but it has not left me altogether. . . . I have the strength of the average woman now, while before the operation I was compelled to be in bed over half the time. Between my menstruations I enjoy as good health as any one could ask. . . ."

Case 9.—Mrs. C., aged 41, a resident of Iowa, consulted me for a bleeding painful fibroid of the uterus in May, 1894. The tumor was interstitial, uniform in contour, enlarging the uterus to the size of a four months' pregnancy. The hemorrhage at menstruation was profuse and lasted six or eight days at a time. The menstrual periods were accompanied with considerable uterine contractive pains. The patient complained of a great deal of heaviness in the pelvis and pains caused by the pressure of the tumor. The patient was weak, rather exsanguinated and nervous. I concluded that the case was a suitable one for my operation. The operation was done May 19, 1894. The lower portion of the uterus was so large and filled the pelvis so completely that it was with a great deal of difficulty that I accomplished the satisfactory ligation of both broad ligaments. However, when the operation was finished I was well satisfied that both uterine arteries had been thoroughly shut off.

The patient improved from the first. There have been no more hemorrhages. I have examined the patient two or three times since the operation, once within six months. The tumor has decreased in size, but has not disappeared. The pains and pressure symptoms are much better. The woman is apparently a healthy woman and does very much as other healthy women. In reply to my letter of inquiry she said March 12, 1896, one year and six months after her operation: "Since the operation I have had but few hemorrhages, while previous to that I had them very frequently. I am now quite regular, though I never go to my full time—about three weeks. I have less pain, but the heaviness still remains. I am better in health and strength than before the operation."

Judging from my other cases I expect this woman to gradually recover. My fear was, when I adopted this operation, that collateral circulation would speedily overcome the result of ligating of the blood supply. Experience, however, shows that the results of the operation are greater the farther away from the operation we get.

Case 10.—Mrs. S., aged 35, a resident of the central portion of the State, came to the Woman's Hospital in August, 1894, to

consult me about an interstitial fibroid. She had borne no children. The uterus was large, regular in contour, hard, and about four by six inches in diameter. It was freely movable in the pelvis. The woman gave a history of severe monthly hemorrhages which lasted anywhere from six days to two weeks at a time. Accompanying the flooding were severe contraction pains. The woman was bloodless, pale, weak and extremely nervous. In all other respects she was normal.

I did my operation on the case in August, 1894, with the assistance of the house staff of the Woman's Hospital. It was easily performed on account of the movability of the tumor and the looseness of the broad ligaments.

September, 1894, the patient wrote: "It is now six weeks since I have menstruated. The previous pains are not any better. My bladder trouble (pressure) is much relieved." October, 1894: "I have menstruated since my last letter. The quantity and length of time was small. Had a good deal of pain the first two days."

November 13, 1894. "Menstruation three weeks apart. I flowed more than usual."

December 17, 1894. "Pains some less. My changes came at the correct date, but was greater in quantity than it should have been."

January 29, 1895. "I flow a great deal more than I think I ought. I have to change my napkins six or seven times a day."

March 25, 1895. "I was a little better my sick week this month. The flowing did not last so long as it did before my operation, but more than is right. My pains are gradually improving."

May 27, 1895. "I flowed very freely and had a great deal of pain this month."

Case 11.—Mrs. Y., the wife of a very intelligent physician of Indiana, consulted me in November, 1894. She had an interstitial fibroid about the size of a four months' pregnancy. She was 43 years of age. I operated on her Nov. 7, 1894. Both broad ligaments were tied, so as to include two-thirds of their bulk. This occluded the uterine arteries on both sides with all their anomalous branches. I have seen this patient several times since her operation and the uterus is gradually lessening in size and the patient's symptoms are subsiding. I expect this case to prove successful with a little more time. In reply to a request from me for a statement of progress, the husband writes March 12, 1894, a year and four months after the operation, as follows: "My Dear Doctor:—In reply to yours of yesterday, I have to say that my wife, on whom you operated Nov. 7, 1894, is doing very well as far as the fibroid is concerned. It has decreased in size some, not a great deal. The menstrual flow on two occasions was quite profuse, but the last two periods have been very scanty only lasting three days, and only using one or two napkins in a day, whereas before the operation she used eight and ten each day for four or five days. She suffers very little pain, in fact none for the last month. Before her operation she suffered constantly. Her general health has greatly improved, and she has gained ten pounds in flesh, is much more cheerful, and in fact improved in every way. . . . My wife is now past 45 years of age, and I believe if the tumor does not increase in size until after the menopause, she will entirely recover."

Case 12.—Miss V., single, age 40, consulted me in November, 1894, on account of a painful bleeding fibroid. She was depleted to an unusual state, and her nervous system was a wreck. She had an interstitial fibroid with the canal of the uterus measuring four inches in depth. The uterus measured approximately three by six inches in diameter. The organ was movable. Hemorrhage occurred only at regular menstruation periods. At this time it lasted a week or ten days and was very profuse. Accompanying the flow was great prostration of the patient and also most excruciating pelvic pressure symptoms. This condition of affairs had been going on for months until the patient from blood drain and harassment of pain had been brought to a deplorable state of health.

March 5, 1894, I ligated the base of both broad ligaments. The operation was accomplished with ease because the uterus was movable and the broad ligaments loose. The patient recovered nicely from the operation. The next two or three menstruations were much more normal, the quantity of flow being very small and the pain scarcely perceptible. The woman was placed on tonics and urged in every way to increase her blood supply. Her nervous system reacted slowly. Her menstruations later became more profuse and was accompanied on several occasions by quite severe pain. While but a short time has elapsed since the operation the patient is gradually improving.

March 12, 1896, one year and three months after the operation, she writes: "The amount of menstrual flow averages

about one-half the amount it was before the operation. Have gained a little in flesh. Have considerable pain. Still have nerves although under better control than formerly."

This patient has improved in many ways. During her intra-menstrual periods she is comparatively well and is able to go about and to do more work than she should attempt, whereas previous to her operation she was unable to do much. While she had been neglected for a long time and her health had reached a low ebb, I can not but believe that she will gradually improve as a direct result of the diminished flow. Her tumor decreased in the first four weeks fully one-third. It has not increased perceptibly to the patient since she left my care.

Case 13. Miss B., age 26, consulted me in January, 1895, for a bleeding intramural fibroid. The uterus was about five inches long and had a canal three and three-quarter inches in depth. The canal was a little irregular. In the fundus of the uterus could be felt two distinct centers of development, one on the interior surface about two and one-half inches in diameter, and projecting from the main body of the uterus one and one-half inches. It was hard and had the unmistakable firm consistency of a fibroid mass. On the posterior surface of the fundus at its junction with the neck was a second center projecting from the uterus about one and a half inches. This mass was irregular and was fully two inches in diameter. The symptoms which brought this patient to me were prolonged and exhaustive hemorrhages and uterine pains. The lady is a vocalist of unusual talent and these symptoms interfered seriously with her profession. The case was a typical one for hysterectomy, especially as the left ovary was enlarged and cystic, but as that would involve the removal of the ovaries the patient objected to this because of the popular but unfounded fear that removal of the ovaries impairs the voice. I therefore decided to perform my operation on the case. When the patient was under the anesthetic I confirmed absolutely by bimanual manipulation my diagnosis as given above. February 1, 1895, I operated on this patient. She left the hospital in two weeks. She did not have an unfavorable symptom. Menstruation practically ceased from the date of the operation. There was but the slightest show each month. No pain whatever. In less than a month she was able to attend to her professional duties and was stronger than she had ever been. This perfect condition of affairs continued until about Dec. 8, 1895, ten months after her operation. At this time I was called because of a sudden attack of severe pain she had experienced in the left side of the pelvic region. The pain was accompanied with profound prostration and shock. I diagnosed ruptured cyst of the left side and advised a laparotomy. In making my examination I was surprised to find a perfectly normal uterus. I performed laparotomy on this patient Dec. 28, 1895, and removed a ruptured ovarian cyst of the left side and punctured a small cyst in the ovary of the right side. This gave me an opportunity to examine the uterus which I had treated by my operation a little over ten months before. On the anterior portion of the organ corresponding to the location of the anterior fibroid described above I found buried in the wall and projecting a half inch, a fibroid center one-half inch in diameter. On the posterior surface, corresponding to the other center which I palpated at the previous operation, was another center distinct but even smaller than the anterior one. These were both exhibited to the house staff and physicians present at the operation. The behavior of this case was most gratifying until the complication of the ruptured cyst arose. This fortunately gave me an opportunity of examining by direct sight the results accomplished by the first operation.

I have no doubt but that those two fibroid centers would have been starved out eventually and the case actually cured without any further interference.

General Summary: Thirteen cases operated on in which more than a year has elapsed since the operation:

Case 1. Age 40. Operation Nov. 15, 1892. Very large bleeding fibroid. Present condition: Tumor much reduced. Hemorrhages ceased. Patient well.

Case 2. Age 40. Operation December, 1892. Fibroid interstitial, size of three months' pregnancy. Profusely hemorrhagic. Present condition: Tumor disappeared. Absolute cure.

Case 3. Operation January, 1893. Interstitial bleeding fibroid of two years standing. Four months after operation. Last report: Tumor reduced, patient much improved.

Case 4. Age 38. Operation January, 1893. Very large adherent interstitial fibroid. Excessively hemorrhagic. Patient bed-ridden. Two years afterward: Uterus reduced almost to normal size. Hemorrhage ceased. Patient well and strong.

Case 5. Age 30. Operation Jan. 8, 1893. Interstitial fibroid three by five inches in diameter. Profuse hemorrhage. Report four months after operation: Uterus normal; hemorrhage ceased.

Case 6. Age 36. Operation Aug. 2, 1894. Interstitial fibroid. Profusely hemorrhagic and painful. Patient much reduced. Tumor three by five inches in diameter. Six months after operation much improved. No later report.

Case 7.—Age 35. Operation Nov. 11, 1893. Incipient interstitial bleeding fibroid. Two years after operation: Tumor reduced; hemorrhage ceased.

Case 8.—Age 35. Operation Nov. 28, 1893. Painful, hemorrhagic interstitial fibroid, size of four months' pregnancy. Two years and four months after operation: Tumor much diminished; hemorrhage ceased; pain less but not entirely relieved.

Case 9.—Operation May 19, 1894. Interstitial, painful, hemorrhagic fibroid. Tumor size of four months' pregnancy. One year and ten months after operation: Tumor slightly diminished; hemorrhage materially reduced.

Case 10.—Age 35. Operation August 1894. Tumor interstitial four by six inches in diameter. Hemorrhage and pain excessive. Not much improved eight months after operation.

Case 11.—Operation November 7, 1894. Tumor interstitial, hemorrhagic, painful and size of four months pregnancy. One year and four months after operation: Tumor decreased in size and hemorrhage ceased.

Case 12.—Operation Nov., 1894. Tumor interstitial, profusely hemorrhagic, painful, and three by six inches in diameter. One year and three months after operation: Tumor reduced; hemorrhage less; pain not improved.

Case 13.—Operation Feb. 1, 1895. Tumor intramural, two centers of development two inches in diameter each. Profusely hemorrhagic and excessively painful; hemorrhage and pain ceased; tumor disappeared, as demonstrated by a laparotomy ten months later.

MINOR SURGERY FOR SUBMUCOUS FIBROIDS.

Pedunculated submucous fibroids may frequently be completely removed through the dilated cervix without interfering materially with the uterus. Unless the tendency to pedunculate is well established however, and the center of development comprising the tumor is the only center of fibroid development to be discovered in the walls of the uterus as shown by careful bimanual palpation, it should be treated by hysterectomy either vaginal or abdominal. An exception to this general rule would be when a pedunculated fibroid is discoverable either in the cavity of the uterus or hanging from the cervix with a long thin pedicle. In such a case the polypus should be carefully removed from the uterus, even though there were other centers of development to be discovered. The uterus as a whole, here, could be dealt with in a later operation if the removal of the pedunculated mass did not sufficiently relieve the symptoms.

The removal of an intrauterine pedunculated fibroid is usually a simple procedure. If the pedicle is small and long and the tumor is in a position where it can be easily reached with forceps, it may be grasped in a strong vulsellum and the tumor twisted until the pedicle is actually twisted in two. This can only be done with thin pedicles. If the pedicle is broad the uterus should be sufficiently dilated (the patient under an anesthetic) to expose the pedicle, if it is necessary to accomplish this the cervix may be divided as high as the vaginal junction. The mucous membrane of the pedicle should next be cut in its entire circumference. Then the remaining portion of the pedicle composed of the blood vessels, connective and muscular tissue should be twisted in the same way that one proceeds to twist off a small pedicle. If

the remaining portion of the pedicle is small it will give way by that treatment. If it is rather large and fleshy, after it has been twisted into a small bulk it may be grasped by a strong pair of curved pedicle forceps and the pedicle severed with scissors or a knife outside of the forceps. If the pedicle is very vascular the forceps may be left in place for six or twelve hours. If this does not seem necessary the forceps are removed and the uterus packed with iodoform gauze. If the forceps are left on the pedicle, gauze should be packed around them. The forceps may be removed in six or twelve hours without disturbing the gauze.

I do not favor attempting to enucleate a submucous fibroid of any considerable size if its principal bulk is buried in the walls of the uterus. Such a procedure is attended with considerable mechanical difficulty because of the position of the tumor in the cavity of the uterus: it is a difficult matter to secure hemostasis in such a location and finally one seldom reaches in such a procedure more than one of several centers of developments of the tumors which are situated in the uterus. In these cases a hysterectomy is more satisfactory.

A cervical fibroid developing toward the mucous membrane, if pedunculated, should be removed in the same manner as that described for removing a pedunculated intrauterine fibroid. A cervical fibroid of small size may be enucleated by incising its capsule, grasping the tumor with a vulsellum, and dissecting it from its bed. The cavity may be closed with buried antiseptic catgut sutures or it may be packed with iodoform gauze.

CURETTEMENT.

In many cases of hemorrhagic fibroids much of the hemorrhage and leucorrhea is caused by endometritis. A safe and oftentimes beneficial treatment for such cases is thorough dilatation of the uterine canal and curettement of its mucous membrane. While it will not ordinarily have a direct curative effect it will frequently relieve disagreeable symptoms for a long period of time. The dilatation should be gradual beginning with Goodell's dilators and afterward exploring the anterior of the uterus with the index finger to discover whether there are any projecting masses into the interior of the cavity. After thorough dilatation with the cervix exposed and grasped with small vulsellum forceps in order to steady the whole organ, a sharp curette should be made to traverse all portions of the endometrium. This should be accompanied with some form of antiseptic irrigation. The whole mucous membrane should be gone over at least three times with the curette, the canal then loosely packed with iodoform gauze, the vagina filled with the same and the patient put to bed for several days. The gauze should be removed in forty-eight hours. After that antiseptic vaginal douches must be given for several days.

THE LATIN PART OF THE BODY.—Medico Lecks: The deceased was shot between the hyoid bone and the insertion of the sterno-cleido-mastoid muscle.

District Attorney Rockaway: Do I understand you to say that wounds in this Latin part of the body are generally fatal?

TWO EXPERIMENTS IN RESTORING LOST SPEECH, OR PARTIAL RESTORATION OF SPEECH BY SYSTEMATIC EDUCATION.

BY L. PIERCE CLARK, M.D.

CRAIG COLONY, SONYEA, N. Y.

While reading one of Professor Sully's articles on Childhood, the thought occurred to me that, in many cases of aphasia in people suffering from apoplexy of the brain and also in the allied disorders of softening and actual breaking down of different portions of the brain, there existed a striking analogy between such attempting to acquire the language anew and the child's attempts in learning to speak for the first time.

I recall two cases that give interesting and peculiar illustrations of this analogy. The first, a subject of right side paralysis, had been unable to speak at all, with the exception of the words, "gully" and "damn." The former she uses at all times and the latter only at periods when she becomes very much excited. This word "gully" she repeats three or four times in varying degrees of tone and pitch, as though each repetition of the word had a distinct and separate meaning and the whole represented some phrase or thought as in normal expression of ideas. The word "gully" is generally accompanied by a knowing look, a gesture of the hand, elevation of the eyebrows and tossing of the head from side to side. These accessories of gesture and modulations of voice are evidently very necessary to herself for proper expression, because when the hand and head movements are interfered with, she becomes very angry and will take no notice of anyone speaking to her, but when released will chatter on in her one word vocabulary, not at all reluctant to engage in conversation with any one upon any subject. When she becomes extremely angry, which she does upon slight provocation, she explosively emits the single word "damn" and covers her face with her hands in apparent shame because of such exhibition of anger. She readily understands most things said to her, as indicated by her quick compliance with one's commands. Her paralysis hinders her from taking an active part in any heavy work, but she is able to keep her own immediate surroundings in perfect order and cleanliness. Of late she has become quite fond of her nurse and, strange to relate, by the persistent endeavor and painstaking care of her instructress, the patient has been induced to copy the word sounds as given to her by her nurse. She keeps close watch of the nurse's lip movements and imitates them closely. It is needless to say that her progress in regaining the language has been exceedingly slow and only by the exhibition on the part of the nurse of those cardinal virtues of the true teacher, patience and tact, has she been able to keep the patient interested. The unfortunate woman can now make known some of her wants and desires quite intelligently, such as "I want a drink of water," and "Let me go out," to say nothing of the disconnected ideas as expressed by single and salient words combined with the appropriate sign language. By this peculiar method, saying "soap—water—towel," and again "crutches—walk—door—air," these phrases are quite readily interpreted into sentences expressing the desire that she wishes to have soap, water and towel, in order that she may cleanse her face and hands, and that she would like her crutches in order

that she may walk out of door to get the air. Although her speech impairment has been very severe, yet the noteworthy fact remains that she is able to sing most of the "airs of the day" that were popular prior to her attack of paralysis; yet this statement should be modified by saying that she remembered the words of only two, but the tune of all. It seems probable that the lesion in her left brain, causing paralysis and loss of speech, has almost completely destroyed the speech center of that side and, while it may be doing some of the work laid upon it by the act of speech regained, yet it seems more probable that the corresponding center on the right side is now being educated.

She is about 44 years old and her already severe speech disorder is rendered much more difficult to be recovered from, because of her advanced years and their natural hindrance to the acquiring of any language. Nevertheless, this case illustrates how long the destructive lesion may last and yet we may hope for improvement if great care and diligence are exercised in their reëducation.

The points of analogy between this case and the child's seem to be as follows: The single word "gully, gully" doing duty for a number of other words and even sentences, as the child says "ha-a, ha-a, do-da, or ka-ke," so she says, "gully, gully," and looks at you in a distressed way, as if to say, "you don't understand my language." Again, it is interesting to note the much earlier return of the noun substantives long before the use of verbs becomes common. Indeed, it seems similar to some system of shorthand where the vowels are dropped from words, only here the verbs are omitted, thus rendering the apparent analogy less complete.

This patient has an interesting way of gaining her object like the child: for instance, as night approaches she will look imploringly at the nurse and gently smooth the coverlet with her hands while repeating the single word "bed" many times or until some one prepares it for her night's rest.

The second case is also a case of right side paralysis. This paralysis has been nearly recovered from, but the aphasic symptoms still persist in a marked degree, although nearly three years have intervened. I endeavored to teach him the language by word lessons.

When asked what he did in the line of work, his reply was "dishes cups plates and saucers, towels, dining room." The next morning, after he had been carefully drilled to pronounce the whole sentence correctly, he replied, "L. McC. (patient's name) wipes ze dishes in ze dining room." When inquiry was made as to whom he referred by the name L. McC., he replied, at first in an uncertain way, "m-e" and emphasized his words by clapping his hands to his breast. The use of his hands so frequently in expressing his disconnected thoughts, is very childlike.

After several weeks of study on his part, he was taught to say "I" instead of "me," as he invariably did at first. Although he refers to himself as "I" most of the time, yet, when he endeavors to speak rapidly or when he grows excited in conversation, he is sure to speak of himself as "me." He grasps the present participle much more readily than the verb itself. Like the child and the very ignorant adult, he very readily falls into the error of forming all his nouns in the plural with final s. He is an audist in the full sense of Professor Charcot's classification, and instead

of watching the lips of the instructor, as the first mentioned case did, he is solely concerned with the sounds of words.

In spelling small words, he quite often reverses the literal order. He always spells phonetically and in spelling some of our Anglo-Saxon words, he makes sad havoc of them. An illustration of his reversing the literal order of word construction is shown in his early effort to spell dog, viz: g-o-d, and cat, t-a-c. He has been gradually taught to spell in the popular way, but on coming to new words, he quite as often as formerly forgets and spells in reversed order. If words be pronounced several times for him prior to his spelling, he is much more likely to spell correctly.¹ He will repeat several times the word he intends to spell before actually doing so, in order to get the sounds of the letters and syllables. Illustration: "house," "scared." This act reminds one quite forcibly of the vocalist's endeavor to get the proper pitch of the note before commencing the piece of music.

In searching for the reason of his spelling in the reversed order, I noticed that he began with the letter sound heard last: this, on account of its being last uttered, was most prominent in his mind. When he spelled nose it became s-o-n-e. The final e was probably not put on the first of the word because it is not sounded in pronouncing. Why he did not place it somewhere within the word instead of at the end, or leave it out altogether, I am unable to state, unless it be for the reason that it does not give as smooth a sound to the word, when completed in any other way.

I am fully aware that, in some respects, he does not follow the child order of acquiring language. This, I think, is due mostly to the retention of his former knowledge of things or at least the skeleton framework of those lost ideas, the islets yet remaining after that general hemorrhagic submersion.

He was asked to name the objects in a picture as shown him (this was done by pointing to some birds and saying "What are they?"). After a moment's study, he replied, "robins." This child-like mistake he is constantly making, using the specific for the generic and vice versa.

It was interesting to note, in the ten months in which I was giving him instruction, the ear out-running the eye in education, when the auditory education would be discontinued, until he was equally educated by ear and eye. It did not occur to me until I had been giving him instruction for eight months, that his hand needed training too. When I asked him one day to write out the lesson, he could do none of it. For weeks he labored to gain control of written language, but he never learned it as well as auditory or visual impressions. I think the partial paralysis of his arm restricted the use of the hand in writing, to some extent.

An example of his wrong phonetic spelling is given in the following words, such being in his orthography: -ben(ch), (ch)air, (sl)eep. His quick ear led me to think that he could be taught to say many things occurring in every day life, in an orderly and connected manner, thus making fairly smooth sentences expressive of his wants. In this I have not been disappointed, as he has acquired the count of money and

¹ Two autopsies have shown me the great difference between the speech center in a deaf mute and in a man who spoke seven languages. Not only was there great dissimilarity of the convoluntary folds, the one being simple and rudimentary in construction, the other being well developed, but there was also marked difference in the cell outline (under high power microscopic lens), thickness of different cortical layers and complexity of cell arrangement.

from such simple words as am, an and man, he is now able to spell and use words like scared, velvet, rabbit, basket, sing, dances, etc.

It will undoubtedly be much more difficult to get him to take up new ideas than it would be for a child, because if his speech center is not entirely destroyed by disease, it is at least damaged to such an extent that education of the opposite side must take place before he will regain much of his lost speech. The destructive lesion has probably abolished the association fibers connecting the word hearing centers in the brain with the word memory center or has interfered with the telegraphic communications to such an extent as to render memory impressions indefinite and imperfect.

This education of the right side of the brain is so rare in man that there is but little precedence or racial predisposition to its development, and, consequently its growth, to meet the exigencies thus suddenly thrust upon it, must be at best very slow and imperfect. For ages children have been taught to use the right hand and develop that side of the body in preference to the left, yet, notwithstanding all this, we occasionally see children using the left hand instead of the right for a long time. I have seen many children in whom the use of the left hand could not be stopped. The most that could be done was to allow them to become ambidextrous, which I am convinced is the best thing that could happen, not only to this but to all classes. I believe that, in these cases, the tracts leading to either side of the brain are equally as easy at first to transmit impressions, but after a few corrections, the nerve impulses become accustomed to traveling along the left side tract to the left center. If it were not for the fact that the left speech center in the child's brain at birth possesses the hereditarily acquired potentiality for development, it seems to me that the right side would take up the task of speech equally as well.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES.

REPORT OF THE COMMITTEE ON SYLLABUS.

(Concluded from page 775.)

BACTERIOLOGY.

On account of its intimate bearing upon the problems of disease, bacteriology, as presented in the medical school, should be studied closely in connection with pathology. The laboratory method should be employed in introducing the student to this subject, and progress is much facilitated when the student possesses an elementary knowledge of practical biology and some training in the methods of laboratory work. It therefore seems desirable to assign bacteriology a place in the first half (semester) of the second year's course, immediately preceding practical pathology which is begun in the second semester of this year. At least three laboratory exercises of two (calendar) hours each a week for fifteen weeks should be spent in the work. Two lectures, or conferences, weekly, may also be employed during the semester. Instead of the usual lecture it would seem advisable to devote the two weekly lecture hours to conferences in which the teacher discusses with his classes the various phases of the problems which naturally have suggested themselves in the course of the laboratory work. Later in the course, when a good store of observations have been made by the class, a few sys-

tematic lectures may be employed to discuss problems which are of a purely theoretical nature, or which are too difficult to be worked out in the class-room.

No single text-book fulfills the requirements of a course of this kind, and while the student may be encouraged to purchase one or more of the standard text-books, a laboratory library with various text-books, and including especially a file of the leading bacteriologic journals, should be provided for the use of the students.

The most important thing to teach the student in the bacteriologic laboratory is *how to work*. He should be instructed in bacteriologic technique so that he masters the various methods and can put them into independent practice. Instead of flooding the student with a great variety of imperfectly studied specimens in a frantic effort to illustrate all the disease-producing bacteria described in the text-book, teach him the technique of the bacteriologic laboratory and the use of the library so that he has the means for working out the problems which will present themselves when he sets out to work for himself.

Each student should be supplied with a full equipment of apparatus and material of a *simple kind* so that individual practice may be obtained in all of the methods demanded in the course. Everything in the student's equipment should be as simple and inexpensive as possible. Cheap tin stew pans and spoons, and tin funnels are more economical than corresponding pieces in glass. Instead of one or two large and complicated steam sterilizers for general class use, a small-sized Arnold sterilizer or a cheap tin apparatus on the principle of the steamer used in cooking should be given to each student. Salmonsens's cracker-box is a better dry sterilizing oven for the beginner in bacteriology than the elaborate ovens of Rohrbeck or Muencke. A simple, double-walled drying oven claims the advantage over an elaborate and expensive thermostat for the purpose in hand.

Every detail in the manufacture of the various kinds of culture media should be carried out by the student. He cultivates his own bacteria; makes all the temporary and permanent preparations; inoculates animals and recovers the bacteria; all by his own handiwork. Instead of depending on the stock of pure cultures with which most bacteriologic laboratories are provided, the teacher should require the student to obtain his own pure cultures of both non-pathogenic and pathogenic bacteria from the *raw material*. The hay bacillus should be obtained from the hay, the potato bacillus from the potato, the *staphylococcus aureus* from a boil or pimple, the colon bacillus from feces, and so on as far as possible.

The pathogenic microbes are naturally of the greatest importance to the student of medicine, and in a short course like the present one it will be found necessary to confine the work pretty closely upon those bacteria which are associated with human pathology. On the other hand, the time spent upon the non-pathogenic bacteria must be short. For the preliminary technical training, however, the non-pathogenic bacteria must be chosen instead of the pathogenic species, which would be unsafe to place in untrained hands. By exposing a slice of sterilized potato to the air the student can usually obtain several varieties of harmless bacteria, together with yeast and mold. Several of these accidental species may be studied in detail upon various culture media, by the hanging-drop, and in stained preparations the separation of

bacteria can be learned by practice on samples of tap-water, while the methods of bacteriologic analysis of water, ice, milk and soil are at the same time illustrated. In this introductory work the general principle of morphology and physiology of bacteria will be acquired by the student and the way opened for the study of classification. With the data obtained in this work the student should now attempt to classify one or more of his unknown species, making use of the keys in some such work as Eisenberg's Bacteriological Diagnosis or Sternberg's Manual of Bacteriology.

When this introductory work is completed the study of some of the disease-producing bacteria may be commenced. A few of the more readily obtained types, like the pyogenic cocci from acne pustules and the *bacillus coli* from the feces of man or the domestic animals, should first be chosen by the student, and the species should be isolated, studied in detail and identified by each member of the class. No rule can be made for the order of this portion of the work, for much will depend upon the supply of material. Aside from those ever-present harbors of pathogenic bacteria, like the skin and mucous membranes, which may be called upon to furnish the student with specimens, material from a variety of pathologic conditions like the pus of appendicitis, the membrane of diphtheria, the spleen of typhoid, the lung of pneumonia, which constantly find their way into the bacteriologic laboratory may be utilized for further class-room study. Here the technique of the smear preparation, alike of secretions, exudates and of tissue can be learned. Suppose, for example, that the surgeon sends to the laboratory a sterilized test tube full of appendicitis pus. Each student in the class makes plate cultures from the pus, and then studies it microscopically as a fresh preparation and finally makes smears which he fixes and stains in various ways. When the cultures develop they are studied in detail and compared with the bacteria found in the fresh and stained pus. Thus the student obtains a good picture of the relation of the bacteria to the morbid process, and incidentally he learns how to work independently. Only a few examples like this need be given to a student to furnish him with the proper foundation for future independent work.

Somewhere in connection with the foregoing work the technique of blood, pus, sputum examination, and the culture test for diphtheria can be introduced and duly emphasized.

The final step in the identification of a pathogenic bacterial species, that is, the experimental inoculation of a susceptible animal and the recovery of the bacterium in the blood and tissues by smears, sections and cultures, may be acquired by the study of a mouse or a guinea pig which the student inoculates with anthrax. Here, also, the technique of a bacteriologic autopsy in all its details can be learned. Once having learned this method the student may test the pathogenic activity of some of the species which he has isolated, as for example, the *bacillus* of diphtheria.

Only when the student has learned to work and has learned from his own experience the relation of bacteria in their various habitats, should he be furnished with cultures out of the laboratory stock. There is then no objection to furnishing him with examples of the more important pathogenic bacteria which he would not be likely to encounter in his class room work, such as the spirillum of cholera and the *bacillus* of tetanus, for instance.

The laboratory study of the bacterial products, of immunity, of bacteriologic therapy, and many other advanced lines of work must be left for elective courses.

The application of the knowledge gained in the above mentioned course should be made in the third and fourth years' courses. In the third year's course, when special pathology is studied, a bacteriologic examination of the morbid material brought into the class room should go hand in hand with the study of the gross and microscopic lesions in all diseases of infectious origin. In the fourth year's course, also, the student should be given the facilities for making bacteriologic examinations of the material obtained in the medical and surgical clinics and at the bedside. In this way the practical bearings of his knowledge of bacteriology will be indelibly impressed upon the student, and constant practice will keep the technique fresh so that, upon leaving the medical school, he can at once apply his knowledge in private practice or in his hospital course.

It must be evident that no laboratory text-book will meet the requirements of a course of this kind. The teacher must supply his students with syllabi prepared to cover the particular work in hand, especially in the early part of the work. In these syllabi careful technique directions should be given, along with suggestions as to the observations which the student is to make and to record, along with appropriate drawings. The slip system of taking notes and drawings has much to recommend it, and it should find its way into all lines of laboratory work. A convenient size of slip for laboratory work is $5\frac{1}{2} \times 8\frac{1}{2}$ inches with portfolio to correspond.¹

LABORATORY EQUIPMENT.

The efficiency of the laboratory depends in a large measure upon the care devoted to the enormous amount of detail required to obtain the proper kind and amount of apparatus and material, to care for it when obtained, and to properly distribute it for the use of students and teachers. This can not possibly be left to the teachers in the various departments, but must be concentrated in the hands of one man who will attend to it impartially for all the laboratories in the institution. This should be the duty of the curator. The person selected to fill this important office must be possessed of peculiar abilities and command the entire confidence of the management of the institution. He should be given general instructions regarding the policy of the management toward the laboratories and complete information as to the resources at his command. Beyond this he should be allowed to work out the details without interference.

The curator must be provided with ample store rooms and a laboratory in which to prepare reagents and fit apparatus. This room should have a table with lead-covered top gently sloping to a drain at one end, water and gas pipes tapped at short intervals with attachment for rubber hose. The curator should be competent to prepare all reagents used in the microscopic laboratories and the ordinary solutions used in chemistry, which means that he should have a good general knowledge of chemistry.

He must first procure for himself all apparatus and material for a manufacturing laboratory, beakers, evaporating dishes and flasks, from the small sizes issued

¹ Teachers unfamiliar with the slip system of taking notes will find a detailed description in Wilder and Gage's *Anatomical Technology*, 1882, pp. 45-52.

to students up to those of several liters' capacity. Graduates, measuring flasks, pipettes, a druggist's balance, a counterpoise balance for weighing liquids, and by all odds let all weights and measures be in the metric system. Bunsen and dental burners, retort stands, tripods, an assortment of corks, xx, from number 1 to 24, rubber tubing, bottles in abundance, from one-eighth ounce morphin up to five gallon seltzer; a list so long that a day or two will be required to make it out. Then in a book he must set down everything that is to be manufactured, adding to this list as new requirements arise, checking off each item as it is finished, making a record of the amount made, when made, indicating the formula used and referring to the place where the formula may be found. Only a small part of his duties can be outlined here, but where special instructions are necessary they will be given under their appropriate heads. Everything issued to students in the shape of material and reagents must be labeled. For this purpose order from the druggist's label printer gummed strip labels the size of a druggist's shake label. A large number of these will be required, but they are inexpensive, about thirty cents per thousand. The following list will do for a basis and may be modified to suit:

LIST OF LABELS.

—% acetic acid.	Fehling's solution,
—% chromic acid.	quantitative.
—% hydrochloric acid.	Flemming's solution.
—% nitric acid.	FeS.
Sulphuric acid.	Grape sugar.
Agar agar.	Guaiac.
AgNO ₃ .	Glycerin.
Albumin fixative.	Gelatin.
Absolute alcohol.	Gentian violet.
—% alcohol.	—Hematoxylin.
Alum carmine.	K ₂ Cr ₂ O ₇ .
Ammonia.	KClO ₃ .
Analín.	Labels.
Analín water.	—Methyl blue.
Baryta mixture.	Miller's fluid.
Benzine.	Methyl violet.
Bismarck brown.	Molybdic acid sol.
Borax carmine.	NaNO ₃ .
Bromin Water.	Oil bergamot.
Canada balsam.	Oil cloves.
Carnoy's solution.	Oil cedar.
Carbol-fuchsin.	Peptone.
— Carmine.	Paraffin, hard.
Chloroform.	Paraffin, soft.
Chlorin water.	Phenylhydrazin chlorid.
Colloidin.	Rubrin.
Congo red.	Salt.
CS ₂ .	—Safranin.
Cupric acetate solution.	Sulphur.
Distilled water.	Sodic carbonate sol.
Dahlia.	Turpentine.
Eosin, aqueous.	Uranic acetate.
Eosin, alcoholic.	Ultramarine blue.
Eosin in glycerin.	Weigert's deodorizing sol.
Fehling's solution,	Xylol.
qualitative.	

A week or ten days will be required to get these out.

IMPORTATION OF APPARATUS AND MATERIAL FREE OF DUTY.

The import duty on apparatus and material used in the laboratories averages about 40 per cent. Provision is made in the law whereby institutions of learning may have these duties remitted.

Each laboratory teacher should be required to make out a list of things he wishes to use and an estimate of the probable quantity. From these the curator makes his list which will include but once the name of every article used in all the laboratories of the entire institution, he can then make his own estimate

of the quantity needed. The curator should familiarize himself with the work being done in all the laboratories so that he may judiciously trim the order to fit the appropriation, so that if economy is necessary it may be applied where it can best be borne. An order was once given including five orders for nitrate of silver, a pound package, a half pound, a quarter pound and two ounce packages. The price varied from \$8 for the pound to a rate of \$16 per pound for the ounces. In a \$2000 order where one teacher's quota was about \$200 he called for 100 grams of an organic preparation the price on which varied from \$1250 to \$1600. This list with price was "o.k.'d" by the purchasing committee and would have been ordered had it not been cut out by the curator. Of the curator's list half a dozen or more copies should be made and sent to as many importing houses with a request for quotations. Ordinarily the price should include delivery at the laboratory.

All material so obtained must be used in the institution and heavy penalties may be exacted should any of it be given away or sold. Two to five months are absolutely necessary to get goods from Europe. Experience, however, teaches that six months is not too much time to allow and if this time is allowed there will be fewer disappointments.

The number of different kinds of apparatus should be kept as low as possible. For instance, have but one style of beaker, one style of flask and one style of evaporating dish.

Five sizes of each will be ample. Each size must have a separate place in the store room and it will be easier to provide places for five sizes of one style of beaker than for five sizes of each of five different styles. A little judicious consulting with demonstrators will make this feasible. It is difficult to detail the annoyance and expense caused by a disregard of this rule. Ten different teachers will call for ten different kinds or makes of the same thing and it will require the services of half a dozen men to take care of the supplies which one might otherwise easily do. When the goods arrive some representative of the institution must go before the collector of customs and make oath that they are intended for use in the institution and that they will not be sold or otherwise disposed of. The goods must be examined by the customs authorities either in the customhouse or at the college when they are unpacked. The latter is preferable and should be requested.

TAX-FREE ALCOHOL.

Alcohol intended for scientific purposes may be withdrawn from bond without payment of internal revenue taxes. Instead of its costing \$2.75 per gallon it may be obtained for about 50 cents, a saving of \$80 or \$90 on a barrel. To accomplish this the curator must make out a bond which is to be signed by two persons who are not officers of the institution, and who are citizens of the United States. This bond must be for an amount at least twice as great as the tax on the quantity of alcohol to be withdrawn at any one time. Thus a two hundred dollar bond will only allow one barrel to be withdrawn at one time, therefore the bond should be for at least \$500 in which case a second barrel may be withdrawn before the first is entirely used up and the bond released. He must now go to a bonded warehouse and get the "description" of a barrel of alcohol and have the barrel set aside, he must take this description together with the bond to the

collector of internal revenue for the district in which the institution is located. These papers are sent to Washington and in a week or ten days a permit to withdraw for scientific purposes, the described alcohol will be received by the curator from the office of the Secretary of the Treasury. Some time and annoyance to all parties to the transaction will be saved if the application be made early in the month so that the alcohol may be delivered before the last day of the calendar month, otherwise it must be rebounded. The curator will now be required to sign a receipt which says he has *already received* the alcohol; this is to be sent to the collector who will then issue an order on the manufacturer or storekeeper to deliver it to the college. A page in the curator's record should be devoted to alcohol. Here is entered the description of every barrel of alcohol, just as in the application, with space for the date of receipt and date of release.

In the bond a time is mentioned when proof that it has been used according to law must be submitted to the collector. This time is usually six months or a year. At the expiration of this time or when application is made for more, the curator must present to the collector this proof, which is simply his affidavit to that effect.

LABORATORY TABLES.

A convenient laboratory table for microscopic work may be of the following dimensions:

Top, 7 ft. 3 in. x 2 ft. 2 in.: from the floor to top of table 2 ft. 6 in. It will have four cupboards 18 inches wide, 12 inches high and about 2 feet deep.

The upper part of the cupboard is occupied by a drawer 3 inches deep. The box containing the student's kit of apparatus just fits in under the drawer. The stools for the students to sit upon while at work should be 22 inches high. This table will accommodate two students at a time and afford accommodation for two classes. Two desks are to be placed with their backs together one inch apart and the space between bridged over by a board 3 inches wide. A gas pipe comes up in this place and runs the length of the table 3 inches above it. A four-way T opposite each place is fitted with a gas tap for each student.

The gas pillars instead of brass should be cast iron with the slit cut larger; these being much more convenient for slipping the rubber tube on and off. These double tables are placed with their ends to the windows if daylight is to be used. If gas is to be used for illumination, burners having chimneys are necessary, as an open gas flame is too unsteady for microscopic work. Some of the patented incandescent gas lamps furnish a white light which is very serviceable. Incandescent electric lights are said to be unsatisfactory owing to the yellow color. Perhaps kerosene lamps are best though somewhat troublesome to keep in order.

This gives each student $3\frac{1}{2}$ x 2 feet of table space which is ample for most of the work but not too much. The door on this cupboard should be fitted on the *outside* where the hinges are placed so that it will swing round through three-fourths of a circle and thus be where it will not be broken.

If it is hinged to the left instead of to the right it will swing under the student's own table and thus not interfere with his neighbor.

LOCKS AND KEYS.

This is rather a large item of expense but it will

not do to get a poor lock. Ability to settle with students satisfactorily depends in a large measure on the integrity of the lock. A Yale lock with corrugated key is not too good. Stipulate with the manufacturer that he mark each key (*but not the lock*) with a consecutive number and this number must be continuous for all the locks, having a similar key in the institution. Each laboratory must be designated by a number or letter, and all the doors having a lock in each laboratory must be numbered consecutively.

Each lock and its two keys will come wrapped in a separate paper or box; take these at random, or better still, mix them up with some care; now take a book ruled as follows with horizontal lines and three vertical columns.

	KEY.	LAB.	DOOR.	
	1	A	24	
	2	B	36	
	3	C	48	
	4	D	91	

In the first column the numbers are consecutive and there are as many lines as you have locks. The first column is headed KEY, the second is headed LABORATORY and the third is the DESK or DOOR in that particular laboratory. After the desks are all in place and numbers on, take the locks and key list, go into the laboratory, begin at one end, select a lock at random, place it in the cupboard or drawer it is to be put on, mark the laboratory and door in their appropriate columns and on the line corresponding to the number as the key. Follow this up till every door has its lock and every line and column on your key chest is full. The curator must do this himself and never trust it to workmen. A carpenter follows, puts on the locks and leaves the key in each one. When this is done the curator takes a portable key board and gathers up the keys. The keys are to be kept in a drawer where they are protected from moisture, dust and the fumes of chemicals. Such a drawer may be fitted up in the following manner:

The drawer selected should be three inches deep. Set in a loose false bottom three-fourths inch from the top. Rule this off in squares one inch each way and where the lines intersect bore holes just large enough to allow the keys to drop down to the shoulder. Number the holes with the gummed paper numbers made by Dennison and varnish the whole drawer. A drawer eleven by twenty-one inches will contain 200 holes. Each hole will contain the two keys of the lock whose number corresponds to the number on the hole.

When desks are to be assigned, one key for each lock in that laboratory is taken on a portable key board and issued as places are assigned. The duplicate key is never allowed to go out of the hands of the curator and taken out of the drawer only to unlock the desks for the purpose of examining the contents, or when first key is lost. If a student loses a key he is charged the full price of the lock. The lock is removed and replaced by another. If a key is broken it is replaced for 25 cents. This prevents students from carrying the keys away and then "going through" that desk the next term when occupied by some one else. A key picked up anywhere can be at once loca-

ted by reference to the chart, while without the chart it is useless to anyone finding it.

MICROSCOPES.

The microscopes should be kept in a special room or cabinet where they are protected from injurious influences. This place should be fitted with shelves and these shelves spaced off with cleats and each space numbered to correspond with the number on a microscope. If the microscopes are of different quality, or not enough so that each student in the class can have one, they may be satisfactorily issued in the following manner: A large sheet of paper (one for each class) is prepared with as many horizontal lines as there are students in the class and with a vertical column for each laboratory day during the term. The names are arranged on this chart alphabetically. Then if there are seven students and only five microscopes they will be issued from day to day according to the accompanying chart.

PATHOLOGY 1892-1893.

	Sept. 21.	Sept. 23.	Sept. 25.	Oct. 1.	
Bennett, G. L.	1	3	5		2
Hamilton, A. C.	2	4		1	3
Mellon, J. S.	3	5		2	4
Smith, C. J.	4		1	3	5
Thomas, A. L.	5		2	4	
Wilson, M. S.		1	3	5	
Williams, H. L.		2	4		1

The numbers being filled in before class time, then no matter who comes first he will get the microscope allotted to him for that day. There will thus be no incentive to crowding. As they are returned at the close of the lesson each is returned to its appropriate place and the curator can see at once when all are in. In case a microscope is injured or any of its parts missing the responsibility can be instantly located by reference to the chart. Lamps, dissecting microscopes, micrometers, oil immersion objectives, drawing apparatus, etc., can be kept and issued in the same way and at the same time. Microscopes should not be allowed to go into the chemical laboratory except with the most careful precautions to protect them from injury. The evolution of injurious gases in the rooms where they are kept or are in use must not be tolerated for a moment. If a large class is to begin the study of the microscope (and every class should study the microscope before studying microscopy), a number of students with some experience should be invited to assist the teacher at first lesson, at least, so that there will, if practicable, be an instructor to each microscope. This will be of real advantage to both the beginner and the student who assists.

STUDENTS' KITS OF APPARATUS AND MATERIAL.

Order from a box factory as many boxes as there are students expected. A good quality of packing box will do, made of dressed lumber, seven-eighth inch ends and one-quarter inch sides and bottom, without covers, of such dimensions that they will fit into the cupboards in the laboratory tables. Boxes 18 inches wide, 24 inches long and 8 inches deep will about fit the tables described, and will cost not to exceed \$12 to \$15 per hundred. Printed lists of the apparatus and material to be furnished each student are provided where laboratory courses in two or more subjects are conducted in the same room and with the same students the outfit for them all may conveniently be combined into one kit. These kits are best fitted

up by arranging the boxes in a row on a table, then taking a tray containing a sufficient number of the first item on the list, walking down the row and putting in each box the number called for. Then follow with a tray of the next article, and so on till all are filled, and lastly put in one of the printed lists. The boxes are then piled up out of the way and are ready for distribution to the students on the day in which classes in the laboratory are assigned. When the box is delivered to the student he is required to take it to his place in the laboratory, check up the kit with the printed list, sign his name and desk number to the latter and return it to the curator as a receipt. These lists are now put separately into envelopes bearing across the end the name of the student to whom it belongs. The envelopes are arranged alphabetically and placed on end in a drawer prepared for the purpose. Each student is furnished with a small tablet of order blanks, plain pieces of paper 2½x5 inches, and henceforth every order on the curator for anything must be written on one of these slips and bear the name and desk number of the student. No orders on other paper will be honored. As these orders are filled, they are checked with a blue pencil and put into a convenient box. As the close of the term approaches these slips are assorted by an assistant and put in the envelopes with the printed slips. When the kits are returned to the store-room at the close of the term the curator and his assistant checks them up with the contents of the respective envelopes, puts a price on each item missing, dirty or damaged, marks the amount on the outside of the envelope and returns to each envelope its contents. Each envelope now contains the complete itemized account of a student and is preserved until a final settlement is made and the student receipts for settlement, when it is to be burned.

The amounts on the outside of the envelopes are entered in the curator's record book in the proper column and the total charged against each student is found by adding together the various charges on his line. The diagram of a page in the Curator's Laboratory Record will explain this more fully.

Everything possible should be issued to the student individually and charged up to him, then if he wishes to be wasteful and extravagant it will be at his own expense. Nothing should be "on tap" except gas and water. Each laboratory should have a gas meter and the gas charged to the class, and the cost divided equally among the members of that class. Slides, cover-glasses and other material are often prepared by the demonstrators for distribution to this class; but this is a faulty, pedagogic method and should not be permitted. Students must obtain everything from the store-room on their personal order and there should be no bottles "on the side" from which they can help themselves. Every one should be required to leave his desk clean and in perfect order on quitting the room. Habits of cleanliness and order should be insisted upon, and any indication of rowdiness repressed. Smoking should not be allowed in any of the laboratories. Young men who believe that it is the student's prerogative to smoke while at work, chew tobacco and spit upon the floors of laboratories or lecture rooms, mark up walls, whittle and break up furniture and otherwise bring into the school the habits of the hoodlum should be promptly advised to become sewer builders, street pavers or enter some other occupation where their habits will not be an

offense to all decent people. The medical profession is surely not in need of such material.

The following lists represent kits which have been found suitable for the work in the laboratories named.

NAME DESK No.
LABORATORY OF BACTERIOLOGY.

See that your apparatus and material is all here and in perfect order, then sign your name at the top and return this slip to the curator.

Check here.

\$ cts.

Agar agar	
Apple corer	
Blotting paper	
Bunsen burner and tube	
Cotton	
Cheese cloth	
Droppers, 3	
Forceps, cover glass	
Filter papers, 1 doz., 25 cm	
Flasks, 1,000 c.c., 3	
Funnels, 2	
Gelatin, 40 grams	
Grape sugar, 5 grams	

Note book, peptone 15 gm., 6 petrie dishes, Pillsbury box, platinum needle, potato knife, granite-ware pan, tripod, salt, slide concave center, sponges for cleaning desk, test paper, 100 test tubes, test tube brush, towel, wash bottle, 2 wire baskets.

STAINS AND REAGENTS IN BOTTLES.

Aniline water, balsam, nitric acid, sodic carbonate solution, glycerin, carbol-fuchsin, gentian violet, methyl blue aqueous.

LABORATORY OF EMBRYOLOGY, HISTOLOGY AND PHARMACOLOGY.

Alcohol, 3 camel's hair pencils, cheese cloth, oblong cover glasses 2 sizes, cover glasses, circles, drawing paper, 3 droppers, eraser and brush, filter paper in strips 1 package, cover glass forceps, fine pointed forceps, 2 glass rods, 1 box labels, tripod magnifier, 12 morphin bottles and corks, 2 teasing needles, 1 box hard paraffin, 1 box soft paraffin, 2 pencils hard and soft, 6 French drawing pens, 2 Pillsbury boxes, 2 porcelain dishes, $\frac{1}{2}$ gross plain glass slides, concave center glass slide, section lifter, 2 pairs scissors fine and coarse, sponge for cleaning desk, towel, tin pan, 5 test tubes, 6 watch glasses, 1 solid watch glass.

STAINS AND REAGENTS IN BOTTLES.

Alum carmine, balsam, borax carmine, eosin aqueous, Carnoy's solution, colloidin and clove oil, chloroform, chromic acid solution, gentian violet, hematoxylon Delafield, hydrochloric acid, Mueller's fluid, oil of cloves, oil of cedar, safranin, 1 per cent. solution silver nitrate, xylol and carbolic acid.

LABORATORY OF BIOLOGY, HISTOLOGY AND PHARMACOGNOSY.

Alcohol, beaker, benzine, blotting paper, glass blowpipe, 1 oz. q. s. bottle, 3 camel's hair pencils, cheese cloth, colloidin, $\frac{5}{8}$ inch No. 2 box cover glasses, cork sheet, drawing paper, 6 drawing pens, 2 drawing pencils, india ink, eraser and brush, dissecting pans, 3 droppers, 12 filters, 2 forceps, funnel, 2 glass rods, 6 4 oz. screw cap jars, one 16 oz. screw cap jar, 1 box labels, tripod magnifier, notebook, 2 needles, paraffin hard and soft, Pillsbury box, box black pins, 2 porcelain dishes, 1 retort stand, 3 retort rings, scissors, scalpel, $\frac{1}{2}$ gross glass slides, sponge, 5 test tubes, test tube brush, towel, wash bottle, 6 watch glasses, 1 solid watch glass.

STAINS AND REAGENTS IN BOTTLES.

Alum carmine, albumin fixative, balsam, borax carmine, chromic acid sol., eosin aqueous, gentian violet, hydrochloric acid, hematoxylon, Delafield Müller's fluid, oil of cloves, oil of cedar, safranin, silver nitrate sol., ultramarine blue.

LABORATORY OF EMBRYOLOGY, PATHOLOGY AND SURGICAL PATHOLOGY.

Alcohol, absolute alcohol, quart tin basin, blotting paper, 3 camel's hair pencils, cheese cloth, cover glass circles, cover glass oblong (18 large, 18 small), drawing paper, drawing pencils, 6 droppers, eraser and brush, fine pointed forceps, coarse straight forceps, weight forceps, box labels, tripod magnifier, 12 morphin bottles and corks, 2 needles, paraffin hard and soft, scissors, $\frac{1}{2}$ gross glass slides, concave center slide, sponge, 3 test tubes, test tube brush, towel, solid watch glass, 6 watch glasses.

STAINS AND REAGENTS IN BOTTLES.

Acetic acid, alum carmine, ammonia, albumin fixative, balsam, Bismarck brown, Carnoy's sol., colloidin, chloroform,

cupric acetate sol., eosin in glycerin, eosin in alcohol, hydrochloric acid, hematoxylon Weigert, hematoxylon Delafield, methyl blue, oil bergamot, oil of cloves, Weigert's decolorizing sol., rubin, xylol and carbolic acid.

LABORATORY OF CHEMISTRY.—A.

Burette, 5 beakers, Bunsen burner and hose, file, 2 packages filter paper, filter stand, 2 flasks, 2 funnels, funnel tube, 2 feet glass tubing, 2 glass rods, hydrogen sulphid tube, mortar and pestle, pincers, platinum needle, 2 porcelain dishes, retort stand, 3 retort rings, sand bath, 10 test tubes, test tube rack, test tube brush, pipe stem triangle, urinometer, wash bottle, water bath, 3 watch glasses, wire gauze.

REAGENTS.

Anilin blue, baryta mixture, congo red, eosin, Fehling's solution quantitative, Fehling's solution qualitative, gentian violet, tr. guaiac, phenylhydrazin chlorid, sulphuric acid, potassium dichromate, sodium nitrite, sodium chlorid, sulphur, ether, alcohol, iodic acid, bromin water, chloroform, hydrogen peroxid.

LABORATORY OF CHEMISTRY.—B.

Aluminum wire, 5 beakers, blow pipe, Bunsen burner and hose, file, filter paper, 4 and 6 oz. flasks, 2 funnels, funnel tube, 2 feet glass tubing, 2 glass rods, hydrogen sulphid tube, pincers, platinum foil, platinum needle, porcelain dish, retort stand, 3 retort rings, sand bath, sponge, test paper, 10 test tubes, test tube rack, test tube brush, towel, pipe stem triangle, wash bottle, 3 watch glasses, wire gauze.

REAGENTS.

Red lead, ferrous sulphid, potassic chlorate, carbon disulphid.

CURATOR'S RECORD BOOK.

In order to reduce book-keeping to practical limits a special book is required. It may be of any convenient size, but where there are a number of laboratories and many students the following is a good size. The page is seventeen and one-half inches high and the double page twenty-three inches wide. It is check-ruled so that there are one hundred horizontal and about one hundred and forty vertical lines on a page. Every other horizontal line is heavier than the rest. The account of each student is placed on one of the heavy horizontal lines, making fifty on a page. Five vertical columns are allowed for the account in each laboratory. The heavy lines are numbered both at the left and right of the double page. The names of the students are written on the left, their accounts in the respective laboratories filled in the proper column and when settlement is made the student signs his name at the extreme right of the same line. Thus each student's account occupies but one double line and is a matter of permanent record. This book must also contain a complete inventory of all the microscopes and other permanent apparatus, with description, manufacturer's and private marks to be used for purposes of identification. Also, alphabetically arranged a list of *everything* in the original purchase, with columns for the amounts purchased each year, and the price paid. This is necessary as a basis for the price to be charged students and for future orders.

WM. OSLER, Pres't, Baltimore.

BAYARD HOLMES, Sec'y, Chicago.

Ohio Cigarette Law. The Ohio law with regard to selling cigarettes has been very materially amended in several respects, and now is, that whosoever sells, gives or furnishes to any minor under 16 years of age any cigarette, cigarette wrapper, or any substitute for either, or any cigar or tobacco, upon conviction thereof, shall be fined not less than \$25 nor more than \$100, or imprisoned not less than two nor more than thirty days, or both, for the first offense; and fined not less than \$50 nor more than \$300, and imprisoned not less than five nor more than sixty days for the second or any subsequent offense.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, APRIL 25, 1896.

VIVISECTION AND LEGISLATION BY CONGRESS.

The anti-vivisectionists, mainly through the societies to prevent cruelty to animals, usually known as Humane Societies, are actively at work coöperating with the society in Washington to secure by Congress such legislation as will prohibit all laboratory experiments on animals in the District of Columbia. If they succeed in obtaining the enactment of the bill now pending, it will close the biologic laboratories attached to the Surgeon General's Department, the Bureau of Animal Industry of the Department of Agriculture, and Marine Hospital Service, and stop the investigations now in progress which promise important contributions to the science of medicine.

These efforts consist in personal solicitations of members of Congress, the distribution of literature setting forth in startling language the cruelties of medical men in general, and especially of the experimenters, petitions to Congress from the allied organizations throughout the country, and personal letters to members of Congress from their constituents, who are engaged in this crusade against investigation and science.

The medical profession throughout the country does not seem to take much interest in the contest at Washington. A few remonstrances have been presented to Congress, but there has not been any general expression of opinion on the part of the profession either in individual or organized opposition. An act of Congress limited in its operation to the District of Columbia, may seem to be a very trivial matter, but it will give such an impetus to the efforts of the propagandists that every State, city and medical college in the country will soon realize the disastrous results of such inactivity on the part of the

profession. The time has surely come when the medical profession of this country should assert itself with spirit, force and determination.

The medical profession is not the only class of citizens interested in this question. The discoveries of the causes and prevention of the diseases of animals by the Bureau of Animal Industry have, perhaps, saved several of the live stock industries from total destruction, certainly so in some of the States.

The Cuban imbroglio in the Senate and the A. P. A. complications in the House seem to have completely arrested the progress of local medical legislation. Senator GALLINGER, in charge of the Medical Practice bill, and Senator BACON, in charge of the Medical Testimony bill, have not been able to secure the consideration of either of these bills by the Senate. The House Committee continues to timidly tinker with the Medical Testimony bill. It seems to be afraid somebody will get hurt by reporting a bill which everybody admits is just and wise. The Hon. JOHN W. BABCOCK, of Wisconsin, is the most efficient chairman of the committee of the House on the District of Columbia it has had for many years and is anxious to promote the progress of scientific medicine by such legislation as the profession may demand, but he lacks the support of the profession throughout the country. If the medical journals could be induced to present the important subjects of legislation before the profession at large and invite attention to the necessity of united action and effort, much good might be accomplished.

The Medical Society of the District of Columbia is the largest and most active medical society in Washington. It has a membership of nearly three hundred, with an average weekly attendance at its regular meetings of about one-third of its membership. It is the body from which all proposed legislation relating to local medical and sanitary matters emanates. Through its committee on Public Health, its members are kept advised of all necessary sanitary reforms, conducive to the healthfulness of that city. For several years past it has been very active in its efforts to secure legislation by Congress to improve the sanitation of the city, but the progress of success has been very slow, because of the lack of interest of the majority of the members of Congress in all matters relating to the District of Columbia.

THE NEGATIVE ETHICS OF SURGERY.

The forthcoming seventh annual report of the Boston City Hospital will contain an essay by DR. DAVID W. CHEEVER, emeritus professor of surgery in Harvard University, upon the morals of surgery. According to the *Boston Medical and Surgical Journal*, this essay will touch upon some of the times and scenes when the surgeon refrains or turns back. One branch of his subject, DR. CHEEVER opens with the reflection: What is more distressing than a death upon the table?

What injures our art more than a fatal operation, which pathology proves to have been useless, or even more, unnecessary?

When to operate: If we confine our selection of cases to those which clearly come under the cardinal rule for operation, namely, to relieve suffering, or to prolong life, or both, we shall have little difficulty in the choice. Is life imperiled? should be the first question. Can we probably relieve the suffering? the second. But when asked to operate, shall we accept only good risks, and refuse the doubtful or hopeless cases?

When not to operate: When to decline is the real difficulty of decision to be met. Do not operate without the full consent of the patient and friends, if possible. See that some responsible party understands what operation you intend to do, and what may be reasonably expected from it.

Do not operate in a state of shock, unless hemorrhage, apnea, or obstruction of the bowels, as in hernia, is going on. If you have time, consider fully the systemic condition of the patient—the integrity of the heart, arteries, kidneys. In a case of no emergency, the age and prospect of life of the patient are to be taken into account. A person of seventy years, having an expectation of life of five or six years, is in a very different category from a youth of sixteen, who has a reasonable expectation of life of sixty years. You would take a risk with the latter which you would not with the former.

Do not operate in glandular infiltrations so extensive as to preclude perfect removal. Do not operate where you can not remove the whole disease, as in a tuberculous organ, if you excise a part; or a sarcoma of the antrum where you can not extirpate the sphenoid cells. To these rules we would make two important exceptions:

1. To relieve agonizing pain operate on any slight chance; for unless the suffering can be palliated, the patient had better die than live.

2. In a "forlorn hope" so called, after you have fairly stated the risk, the patient is entitled to an operation if he wishes, and if he takes the responsibility: but even here you must limit yourself to cases where there is a single, or some, chance of success.

During an operation when must we stop? When the patient fails? Not always. That failure may be due to ether, or even to simple nausea. Pause, stimulate, consider maturely, before abandoning your task.

Stop when you have reached the end of all you can take out, in a malignant tumor, for instance.

Stop in an operation in the abdominal cavity when a glance or touch reveals that the tumor is not removable, and has grown into vital parts. Do not explore it farther, or you will get where you can not stop.

Stop in an operation on the surface of the body when stopping will not imperil life as much as going on: in syncope, with a weak pulse, with sighing respiration, with a colliquative sweat.

"THE THOUGHT MACHINE."

Those who confine themselves to the regular types of literature or science miss a great deal of pleasure. The most perfect illustrations of humor are most solemnly and seriously meant. There can, for example be nothing more provocative of mirth than some of

the publications to-day being issued by the homeopathic press. The *Medical News* a year or more ago gave some selections from one such book that would have warmed every cockle of Mark Twain's heart if that excellent authority in humor, though not in medical science, were not a homeopathist himself. Likewise in the many periodicals, books and leaflets devoted to faith-cure and such delusions there is hardly a page that does not delight the lover of fun.

We have before us a number of one such periodical labeled *Freedom*, in which is a full-page description of "A Wonderful Machine." It is put forth in all seriousness—an added element of the ludicrous—and we only regret our inability to make more lengthy quotation than we have permitted ourselves. This truly wonderful machine is said to have been devised by JULIUS EMMNER of Washington, D. C. If the machine could do what is suggested by the name and description, one should at least be placed on the desk of every member of Congress, and its uses would seem of marvelous applicability in many walks of social and professional life.

From the description given it would appear that the machine bears much resemblance to the phonograph, but there is this marked difference, instead of talking into it, one only thinks hard at it. Fearing that we may misunderstand or misreport the account we are compelled to quote:

"The 'Thought-Machine,' continued the inventor, 'effects the tangible coupling of material and immaterial forces, with electricity as my motive power and chemistry as my recorder. The chemically sensitized surface of a cylinder, while undergoing decomposition by the electric current, receives the magnetic thought-waves which stream from the physical brain of the operator, and portrays them—vibration upon vibration, form upon form—with microscopic fidelity, in an imperishable message. Now, the separate actions of all these forces—electricity, the chemical sensorium, and the magnetic currents of the human brain—have long been thoroughly understood. But the Thought-Machine combines the actions of these three distinct forces in an apparatus where such faultless electrical, chemical and mechanical conditions are subject to the operator's will that the delicate mind-currents, conveying his thoughts, are engraved upon the sensitized surface as a continuous, unerring registration.'

"MR. EMMNER then requested silence for a moment seated himself before the Thought-Machine, adjusted it for recording and opened the electric circuit. The mechanism began its smooth, noiseless motion, the cylinder revolving on its axis, pressed softly by the electric pencil passing along its face. Then, as the inventor brought his head within a foot of the recorder, directing his mind upon the machine, a thin, cloud-like thread wound spirally about the glistening film, from left to right. This was the thought record, which after several minutes of silent work, had overspread the entire film with its smoky tinted coils. The record finished, MR. EMMNER released a circuit button, the mechanism stopping as noisily as it began, and invited a test of the record, no better idea

of whose accuracy can be given than to state that by arrangement with the inventor, a number of thoughts forming the descriptions in this article have been thought into and received from the Thought-Machine, in perfectly logical sequence. The wizard of thought then continued to chat pleasantly to the correspondents.

"Some notable developments from experimenting with thought-records," said he, 'are that languages, as well as words, have each their distinct, intelligible records; that emotions of like kind have like vibratory records, while superimposed records of violently different emotions tend to produce temporary insanity in the re-thinker; that animal 'sagacity' so-called has likewise a characteristic vibratory record, well nigh amounting to a language, but also deleterious to the human re-thinker; that thought is the explosion of the mind as vocality is the explosion of the mouth; that a captive human being, held forcibly against his will within recording distance of the machine, involuntarily registers his thoughts; that thought has color as well as vibration, and that it is conveyed, with varying distinctness, to all the ganglionic and nervous-vital centers of the body.

"The uses of the Thought-Machine will be more extensive than can possibly be predicted,' continued MR. EMMNER. 'To the law it will be invaluable for the involuntary conviction of criminals by the automatic registration of the thoughts of their crimes. The last wishes if the dying can also be given an irrefutable record, of vital importance in the settlement of estates. In medicine it must prove equally indispensable for treating the insane, whose condition can be unerringly found by this delicate but unsympathetic examiner; while, in connection with the electroscope, it will prove an inestimable help for diagnosing nervous mental diseases. In fact, a broad area for experiment in chemical electricity and psycho-physiology is opened by the new machine.

"To the business man in the intricacies of commerce, and to the author in the niceties of higher composition, it will prove alike a boon, and to inquirers in every field of science, it will furnish a new and reliable means of verification. So that the practical effect of the Thought Machine in our daily life will thus be to save much of the most valuable thought of the world which now goes to waste, and to lighten labor by facilitating its transmission to mankind."

It will be noticed that there is a complete omission to reproduce some of these records—these "thin cloud-like threads wound spirally about the glistening film, from left to right," and no hint is given as to the interpretation or nature of this new language which is to take the place of "vocality, the explosion of the mouth," of the rest of us ordinary mortals. Why should the "wizard of thought" much longer continue to "chat pleasantly, etc.?" Why shouldn't he look hard at his hearers and work his thoughts by will power directly into their minds, without the aid of any vocality or crude thought-machine. The professional reader will at once notice the medical suggestiveness of this new kind of X-rays. RÖNTGEN is certainly outdone. Why should not the machine be brought before an abnormally acting stomach, or hidden tumor, and by extraordinary "sensitization" make the

viscus or neoplasm think hard at the apparatus, and thus learn *its* thoughts—for according to the theory it must have, nay, *be* "thought."

What an opening is disclosed to medico-legal science! We suspect BERTILLOX must look to his laurels as well as RÖNTGEN, and that our police bureaus and courts of justice will soon be outfitted with Thought-Machines. What a great saving in all legal trials! All the judge and jury will have to do will be to arm themselves with a machine like a "kodak," and go pointing it at the criminal, witnesses, and lawyers, and, lo! on the revolving cylinder will be the record of every hidden thought divulged in "thin cloud-like threads, wound spirally, etc."

The editor of *Freedom* is able to go the inventor "one better," and appends an editorial footnote as follows:

["A simpler explanation of this apparently marvelous thing is that thought is a substantial entity, and is capable of being photographed. And the Thought Machine is nothing more than a camera adapted to this purpose. I have known for many years that thoughts are things, and that they can be charged with a purpose and sent anywhere, no matter how far, in order to fulfill their mission. I have *seen* thought myself. I have seen it pass as a fine, silvery, shimmering stream from me to a patient when I have been treating him. It could have been photographed I am sure; and then by the process of enlargement, which photographers employ, I have no doubt but its meaning could have been made to appear—if not in words, then in unmistakable symbols, or perhaps harmonious musical chords, or softly blended colors—something anyhow that would have meant harmony and strength and beauty.—ED.]

Verbum sap.!

THE DESPISED OFFICE OF MOTHERHOOD.

"You dear sweet baby! Mother feels perfectly drefful 'cause you didn't win first prize." In these terms, a handsome young woman, fashionably and expensively clad, at a recent exhibition in the city of New York, addressed—*her cat!* A crowd of other anxious "mammias" and "muzzers" washed and combed and beribboned their "blessed darlings" before each day's opening of the cat-show.

These are the women, daughters of wealthy parents, who announce before their marriage that they do not intend to have any children, who declare that a rosy infant nursing at its mother's breast is a vulgar, indecent spectacle, and who consign to a menial the task of dressing and feeding the little babe whose conception they strove by syringe, sponge or baudruche to prevent, and these failing sought to forestall by other means of which their knowledge is a fearfully suggestive fact. The naked South Sea Islander, who intuitively worships the unknown God of Nature, or the pagan of the churches, who calls his God Buddha or Allah and his Savior Saddartha or Mahomet, has far less need of Christian missionary endeavor than these

bejeweled creatures of fashionable society, who are defying the precepts of the Jesus they profess to revere and the sweet example of the blessed Mary, who sanctified the office of motherhood in her own person. Physicians will do well to ponder on this aversion to child-bearing, which ought to be the ambition of every healthy, happily married wife.

A new word from the prolific Greek—*anerotic*—has come in vogue in the course of the discussion as to the causes of the admitted unfruitfulness of the better classes of American women. That the majority of the women of this day are endowed with only a moderate degree of sexual propensity is undoubtedly the fact, and by many this may be regarded as a providential provision against immoral indulgence by the unmarried and a restraint upon conjugal excesses, but apart from the extinction of a normal physiological function, which can not be commended, the unproductive effects upon the community are deplorable. The deficiency of children in modern well-to-do families and the consequent diminution of paternal, filial and fraternal bonds are aiding to destroy that most charming institution of our grandsires, the ideal American home. The new woman craze is the natural outcome of the weakening of home duties, ties and demands. Having no longer the absorbing occupations of the nursery, play-room and domestic schooling, to engage time and thought, the epicene woman mounts her bicycle, joins her club and fondles cats and dogs instead of children.

A careful inquiry into the ultimate causes, which have made maternity unattractive will probably find that reprehensible social customs are first responsible for the physical deterioration and the latter the proximate cause of unfruitful union. The demands of modern fashionable life and its pseudo-fashionable imitators are so largely in the direction of public entertainments where display is the feature, that domestic reunions and harmless diversions have fallen into disuse and the daughters of plain folk, like those of the wealthy, are only interested in meretricious theatrical doings and the insanitary indulgences of the ball-room. Intemperate dancing by adolescent girls is more to blame for genital disturbances than any one other cause. The homely dances which began and ended early have been supplanted by those which do not commence until after the hour when the young girl should be asleep in bed, and continue until daylight, the jaded creature having to overcome her exhaustion by stimulation with beef tea, strong coffee, champagne, or the latest maintainer of energy, kola. It requires no profound knowledge of female anatomy and physiology to realize that an immature menstruating girl can not sit up until midnight and then undergo the physical exertion of a ball-room belle for hours on successive nights without establishing a train of symptoms indicating serious impairment of her normal

sexual development, especially when that girl super-adds a vicious style of dress, which aims to diminish the diameter of her waist beyond the possibility of the contained organs remaining in situ. Though mothers and daughters do not heed, is the family adviser any the less derelict, who does not show them how pressure upon the mammae results in their atrophy and unfits them for their prime purpose and how displacement of the pelvic viscera induces painful strains, which are so common that the XXth century woman without a backache ought to be the envied of her sex. The normal function of the sexual period has come to be so abhorrent, that the interference of the menstrual recurrence with prospective gaieties only incenses the pleasure-seeker who attempts to retard or prevent it at any hazard. Whether lack of the development of the erotic sites of the female sexual apparatus is a progressive degenerative incident due to these and other concurrent causes and is a primary reason for the avoidance of conjugal duties, the fact is that such a condition is becoming a frequent topic in medical discussions. Inquirers as to the causes of prostitutions agree that sensual gratification is an inconsiderable factor in the recruitment of the class of public women. The love of dress, thirst for excitement, acquiescence for the sake of the professing lover, evil example, curiosity, poverty, unwillingness to work, all these have their victims, and ruin hundreds where the mere gratification of passion allures individuals. Sociologists may look for the explanation of the frequency of divorces in the dissatisfaction of husbands, who find themselves bound to women to whom sexual relations are repugnant, whose horror of maternity is overpowering, and whose unwelcome offspring are denied their natural sustenance through maternal incapacity or selfish disinclination. The surviving daughter is sure to be trained in her mother's violation of all the laws of female hygiene and to become in turn even more indisposed and less fitted for maternity.

The remedy for the unnatural aversion to motherhood, whatever its cause, while within the province of the medical adviser, is not to be found in aphrodisiac medication. "Give him bromid; don't dose me with damiana," significantly protested a wife in whom an injudicious physician was trying to arouse the sleeping venery. The removal of physical impediments, such as preputial adhesions, must be supplemented by instruction as to conjugal duties and responsibilities and by reform in social customs, which latter, however, it is perhaps idle to expect in this generation.

THE JOURNAL SPECIAL.

Take the JOURNAL special train for Atlanta. Stop over tickets allowed, on return trip, at Chattanooga and other points. Leaves Chicago, Sunday, May 3, 12 M.; Big Four Route, Illinois Central Station.

EXCRETORY MATTER IN EXPIRED AIR.

An interesting series of observations is being carried on under the direction of PROFESSOR ATWATER of the Wesleyan University at Middletown, Conn., on the respiratory excretion and the animal heat in the human subject. PROFESSOR ATWATER and a colleague have for several years been perfecting the apparatus and have now probably as perfect a respiration calorimeter as is possible at the present time, and have, moreover, found among their associates intelligent and willing subjects for experiment; one of them, PROFESSOR TOWER, of the Wesleyan University, having already served for one series of observations covering five days, and a colleague, MR. A. W. SMITH, for a still longer series. This is a kind of physiologic experimentation to which not everyone would be willing to submit, and yet one that can not be objected to by any anti-vivisectionist.

The earlier experiments of PETTENKOFER with this method of determining the respiratory products were necessarily imperfect and his results as regards the measurement of the heat given off still more so, and at best only coarse approximations to the facts. By enlisting in the experiments the intelligence of the subjects and securing an especially high grade of this requisite the value of the investigation ought to be materially augmented, and altogether the conditions in these experiments appear to be particularly favorable for the attainment of valuable results. Their theoretical importance in elucidating the questions of physiologic conservation of energy is very great, but more interest will probably be generally taken in their practical applications in demonstrating the value of different diets as favoring work in general or in employment of various kinds. In this way they can throw light on many economic problems and be of direct service to the world.

PROFESSOR TOWER has published an account of his five days' seclusion in the calorimeter chamber, which is of interest as showing the easy practicability of such experiments. When the results are fully worked out and given to the world one can better judge as to their success and value, which last can hardly fail to be considerable. With the continuation of the observations it is to be hoped that many important questions will be solved, and that the more or less imperfect data obtained from PETTENKOFER's observations which have been so long one of the chief sources of our information on this subject, will be very extensively and adequately supplemented.

CORRESPONDENCE.

"A Question of Priority in the Abortive Treatment of Typhoid Fever."

To the Editor:—"La politesse ne coûte rien." In the issue of the JOURNAL of March 21, 1896, under the caption "A Question of Priority in the Abortive Treatment of Typhoid

Fever," there appears over the signature of Arthur J. Hall, a remarkable criticism of the paper on typhoid fever which I read before the Mississippi Valley Medical Association at Hot Springs, Ark., on Nov. 21, 1894. From this critique I make the following quotations: "Dr. Woodbridge expounded his so-called abortive treatment of typhoid fever, giving three polypharmic formulæ, with instructions for their use, and claimed he had had twelve years' experience with this treatment. The formulæ contain guaiacol carbonate to the extent of 33 $\frac{1}{3}$ per cent. This claim of twelve years' experience with guaiacol carbonate is at variance with a statement of the manufacturers of the drug." Now it is not true that I did in this paper or in any other written or oral communication, claim to have had twelve years' experience with any one drug or any single combination of remedies. On the contrary, I have on several occasions denied having been guilty of any routinism in the treatment of typhoid fever, until forced to it by the necessity of simplifying (that it might be published in an intelligible form) the somewhat complex course of medication which constitutes my method of managing the disease, and later by the results which I have invariably obtained from the use of the tablets and soft capsules which are prepared for me by Messrs. Parke, Davis & Co.

Moreover, I have outlined in several of my articles the whole series of investigations in the fruitful field of the application of antiseptic medicine to the cure of diseases, which finally culminated in a choice (for the abortive treatment of typhoid fever) of the three formulæ mentioned.

If Dr. Hall will turn to page 210 of my book, "Typhoid Fever and its Abortive Treatment," he will find this explanation: "The narration of my failures and partial successes with all of the various agents from turpentine and the sulphites to iodine, which were one after another used and abandoned, would be a waste of time and space and would, I fear, exhaust the reader's and hearer's patience, although it might save future explorers the trouble of testing unreliable antiseptics. The only one of these earlier remedies which I still occasionally use is turpentine. Creasote has been displaced by its active principle, guaiacol, and that by the more potent and non-toxic guaiacol carbonate."

Thus the evolution was a natural one from creasote to guaiacol absolute and from guaiacol absolute to guaiacol carbonate: just as eucalyptol was suggested to my mind by the use and beneficial effects of turpentine.

If Dr. Hall had taken the trouble to inform himself he would have learned that the whole subject has been discussed until it has become so trite that there is nothing new to say upon it, and if he will give the matter that careful consideration which its importance merits, he will discover that something more than the "excellent results" which he has observed from the "so-called Woodbridge treatment" may be expected if it is intelligently applied, and that the "amelioration of symptoms" which may be obtained alike from carbonate of guaiacol and many other intestinal antiseptics does not constitute all of the results of the "abortive treatment" for typhoid fever, "the claims" of which are "well-founded."

The article closes with: "Dr. Woodbridge may be entitled to credit for introducing the drug to the profession in the United States, but I believe it would have redounded more to his credit had he told us to begin with that he imbibed his inspiration from the experiments of Dr. Hoelscher, of Mühlheim on the Rhine."

I regret having left anything unsaid or unwritten which could have "redounded to his (my) credit," but I had advised an abortive treatment for typhoid fever more than ten years before Dr. Hoelscher published or made his experiments, and had used carbonate of guaiacol long before I ever heard of Dr. Hoelscher and long before Messrs. Schering and Glatz (in 1894) issued the little advertising circular from which it appears that

Dr. Hall extracts the learned quotation which he evidently wishes us to accept as coming from the *Allgemeine Medicinische Central-Zeitung*.

For comparison I reproduce Dr. Arthur J. Hall's quotation and beside it the original, which the advertisers do not mark as a quotation.

FROM DR. ARTHUR J. HALL'S
LETTER.

In the *Allgemeine Medicinische Central-Zeitung*, 1893, Nos. 45 and 46, Dr. Fritz Hölscher gives an interesting account of his experiences with guaiacol carbonate as an intestinal antiseptic, more especially in typhoid fever.

I am at a loss to understand by what peculiar process of cerebration Dr. Hall creates evidence that Dr. F. von Heyden's successors at Radebeul, Germany, had never heard of my having treated typhoid fever with guaiacol carbonate because Messrs. Schering and Glatz of New York have mentioned the fact that Dr. Hoelscher had done so, and while I have no means of knowing that Dr. Heyden's successors had then or have yet heard of me, I protest against Dr. Hall making public declaration to the contrary unless he has some better source of information than an advertising circular issued by a New York drug house.

I protest, too, against Dr. Hall taking it upon himself to fix so high a standard of morality for me, while he has himself garbled my language, misstated my claims, and accused me of an offense of which I am *not*, and he *is*, guilty.

Can it be that he is endeavoring to pose as a reader of a standard German medical periodical which he seems not to have seen? Does he wish to palm off a quotation from a little advertising circular of an American drug house, as coming from a German publication of recognized standing, without giving the credit which is justly due the advertiser, while criticising me for failing to mention the partial success of Hoelscher in the treatment of typhoid fever, which I had so completely mastered so many years before?

I am, etc., JOHN ELIOT WOODBRIDGE, M.D.

A Wisconsin Diploma Mill.

SEATTLE, WASH., April 10, 1896.

To the Editor: Knowing that the JOURNAL as well as its many readers will give its help to discourage frauds in the profession, and especially in regard to "Bogus and Cheap (so-called) Medical Schools and Colleges," I therefore send you the following "interesting" correspondence:

A few weeks ago my attention was attracted to the following advertisement which appeared in the *Pharmaceutical Era* bearing the date of March 12, 1896:

"WANTED Pharmacists who desire legally to append M.D. to their name. Address Medico, 1809 Fond du Lac Ave., Milwaukee, Wis."

I at once wrote to the "Medicus" and in due time received the stock printed letter marked I. This last letter I also answered stating that I was very desirous to practice in the interior and for him to forward the questions. In due time letter marked II came to hand and the questions to be answered. With these I also enclose marked III.

Is it possible that the Wisconsin legislature granted a charter to such an institution? Can it be possible that a city has such an array of eminent medical men as she contains to day, will permit such an *ulcer* to live and thrive in their midst? Can not something be done to prevent the traffic of medical diploma vending? There is no telling how many of these bogus sheepskins have been sold. Medical men of repute and standing should by all honorable means stamp this Hydra out of existence.

FROM SCHERING & GLATZ'S
ADVERTISEMENT.

In the *Allgemeine Medicinische Central-Zeitung*, 1893, Nos. 45 and 46, Dr. Fritz Hölscher gives an interesting account of his experiences with guaiacol carbonate as an intestinal antiseptic, especially in typhoid fever.

Medical examiners on boards of health should carefully scrutinize each and every diploma that comes under their observation, that it should not read emanating from this "institution." It is, too, very deplorable that such a well known and worthy journal as the *Pharmaceutical Era* should lend its columns to such an enterprise.

The so-called president, directors, secretary and treasurer are all "M.D.'s" and yet I can not find any of these names among the thousand medical men in the Medical Directory of the United States.

Trusting you will give this such publicity as your wisdom may think worthy, I remain

Very respectfully, EMIL BORIES, M.D.

I.

WISCONSIN ECLECTIC MEDICAL COLLEGE,
1809 Fond du Lac Avenue,
MILWAUKEE, WIS., March 24, 1896.

MR. EMIL BORIES, Seattle, Wash.

Dear Sir:—Replying to your letter of application of March 19, for particulars of our College, we have pleasure in forwarding with this our latest prospectus, which if you will carefully go over, will explain to you our mode of working. And after reading, if you will submit to us, fully and confidentially any doubts or seeming difficulties which may have suggested themselves; will on our part to do all we can to give (in extenso), thoroughly satisfactory replies and explanations.

Further, it would be of great benefit if in your reply, you would give us some idea of what medical knowledge or experience you have. This knowledge will enable us the better to advise you how to act, so as to obtain the desired M.D. degree. The obtaining of a medical diploma is a very great event in any person's life, as the legal append of M.D. gives to its holder an authority, and a certain position which can not be obtained in any other way. It raises the individual in the social scale no matter who he, or she may be.

We would ask your attention to the fact that we have this week made very large reduction in our fees which ought to bring them within the reach of all who are qualified. The fees which are inclusive of charges of every kind are reduced to \$35.

We shall be glad to, and indeed expect to hear further from you, and to answer any or all questions you may desire to submit.

We are yours very sincerely,
WISCONSIN ECLECTIC MEDICAL COLLEGE,
FRED RUTLAND, M.D., President.

II.

WISCONSIN ECLECTIC MEDICAL COLLEGE,
1809 Fond du Lac Avenue,
MILWAUKEE, WIS., April 3, 1896.

MR. EMIL BORIES, Pharmacist, Seattle, Wash.

Dear Sir:—Yours of the 29th received with thanks. I enclose with this our examination blanks. The instructions are very simple, make your answers by number and also make your answers as brief as is consistent with making yourself clearly understood. Then, when through take your answers to a Notary Public and make a declaration in his presence that, they are your own unaided work. Send your answers to us and if found to be 75 per cent. correct, we can legally confer the degree and issue diploma.

Yours very respectfully,
FRED RUTLAND, M.D., President.

III.

EXAMINATION BLANK.

1. State your name in full, age and nationality.
2. Have you ever studied medicine in any medical school or college— if so, for how long.
3. Or under a preceptor or physician.
4. Or in private studies.
5. Have you ever practiced medicine either as a profession or otherwise. For how long.
6. What school of medicine do you prefer.
7. What do you understand by the term an element.
8. Define a chemical change.
9. Define the term Decomposition.
10. Define the term *Materia Medica*.
11. Define the term Therapeutics.
12. Define the term Pharmacy.
13. Define the term Toxicology.
14. Define the term Obstetrics.
15. Name say thirty or more remedies which you consider in the front rank as being of most service to man.

16. What is the office and use of the Brain in the human anatomy and to what diseases is it most liable?
 17. Same of the Lungs.
 18. Same of the Heart.
 19. Same of the Liver.
 20. Same of the Spleen.
 21. Same of the Kidneys.
 22. Same of the Intestines.
 23. Give an outline of how the bony frame work of the body is built up and name some of the more important bones.
 24. Same of the Arterial and Venous system.
 25. Same of the Nervous system.
 26. Outline your treatment of Bronchitis, Cancer, Consumption, Diphtheria, Erysipelas, Fever (scarlet), Measles, and any other troubles you have particularly studied or treated successfully.
 27. What treatment would you give a case of poisoning by Belladonna, Digitalis, Chloroform, Carbolic acid, Nitric acid and Nit Silver.
 28. What is a Tonic Medicine?
 29. What is an Alternative?
 30. What is an Antipyretic?
 31. What is a Cathartic? Name two or more of each of these classes.
 32. What is the first stage of labor? What is the second stage of labor? What is the third stage of labor?
 33. How would you reduce a dislocation of the elbow joint?
 34. How would you reduce a dislocation of the hip?
 35. What is the essential difference between sterility and impotence?
 36. Do you consider it good practice to administer as a regular thing such a class of medicines to a sick person which would under ordinary circumstances make a healthy person sick?
 37. Give your ideas of what characteristics a physician should have to make him or her successful.
- Please return this list with your reply papers.

Dr. Reuben D. Mussey.

LEXINGTON, KY., April 20, 1896.

To the Editor:—My attention was called to your very interesting and able address contained in the JOURNAL of April 4 several days after I had written you acknowledging the receipt of a number of copies of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. I was a student under Dr. R. D. Mussey when he was a professor of surgery in Miami Medical College in 1856 and 1857, and he was my first teacher in surgery. He used to exhibit the specimen of the neck of fractured femur with bony union within the capsular ligament, the same that he took to Europe with him and showed to Sir Astley Cooper. Our class was always of the impression that he was the first to call attention to the fact, and I believe he so stated in his lectures. I saw in the last JOURNAL that Dr. Edward J. Brown advises that this honor belongs to Dr. Phineas Spalding, of Haverhill, New Hampshire.

If so, Dr. Mussey was never aware of the fact, and he was accorded the honor generally by surgeons of America. I was delighted to read your address on the biography of a great and Christian surgeon. I remember vividly his counterblast on tobacco and lectures on intemperance, and to which he would often refer in his lectures. With kind regards,

I remain yours, etc., F. M. GREEN, M.D.

The Oldest Alumnus.

CONCORD, N. H. April, 13, 1896.

To the Editor:—The JOURNAL of April 11, p. 748, says: "Death of the oldest Alumnus of Jefferson Medical College." Now while that is true, yet I would call your attention to the fact that the AMERICAN MEDICAL ASSOCIATION has a member in Newport, N. H., who was 86 years old February 17, and therefore from February to September older than Dr. Gemmell, but as he did not graduate at the Jefferson Medical College until 1836, he has not the distinction of being the oldest alumnus.

Dr. John L. Swett was born in Clairmont, N. H., February

17, 1810. Graduated from Jefferson Medical College, in 1836, and located in Newport, N. H., the same year. He has done a good business and commands the universal respect of the profession and the public.

Yours truly,

G. P. CONN, M.D.

"The American Medical Association."

TECUMSEH, MICH., April 20, 1896.

To the Editor:—"The AMERICAN MEDICAL ASSOCIATION—what is it?" A "Correspondent" asks the *Record* the above inquiry (see p. 843). It would be a difficult matter to state whether or not the above paragraph emanated from the brain of the editor of the *Medical Record* or the printer's devil; it is unworthy of the former and scarcely worthy of the latter. Permit me to state for the benefit of the *Medical Record* that the AMERICAN MEDICAL ASSOCIATION is the only association that represents the medical profession in this country; that it is large enough to hold the brainy editor of the *Record*, and that it is even worthy of every "effort that he may make to get there"; that it possesses the best medical journal in America, and its editor knows how to run it. Very respectfully,

J. F. JENKINS, M.D.

ASSOCIATION NEWS.

Rush Monument Committee.

In consequence of the tardy returns from the members of the AMERICAN MEDICAL ASSOCIATION, who were constituted members of the Rush Monument Committee, returns of the several collections they have made will be received by the Secretary, Dr. George H. Rohc, Catonsville, Md., until Thursday, April 30, by which time it is earnestly hoped the pledges made at the Baltimore meeting will be redeemed. It must be remembered that these obligations were voluntarily assumed and without a dissentient voice. It is expected, therefore, that the returns to be reported at the coming annual meeting will be proportionate to the enthusiasm with which the present plan of obtaining contributions was adopted.

ALBERT L. GIBON, M.D., Chairman.

8 West 127th Street, New York City.

Section on Neurology and Medical Jurisprudence.

The following subjects will be discussed and papers presented:

THE ETIOLOGY OF INSANITY.

1. Discussion opened by W. F. DREWRY, Petersburg, Va.
2. Paper by SMITH BAKER, Ithaca, N. Y.
3. Intoxication and Insanity, J. T. SEARCY, Tuscaloosa, Ala.
4. Remarks by FREDERICK PETERSON, New York City.
5. Inebriety in the Etiology of Insanity, J. N. QUINBY, Jersey City, N. J.
6. Duestro Case and Its Bearing on Alcoholism Epilepsy and Paranoia, LUDWIG BREMER, St. Louis, Mo.
7. Insanity in Children, E. D. FERGUSON, Troy, N. Y.

EXPERT MEDICAL TESTIMONY IN DISPUTED MENTAL CASES.

8. Discussion opened by CHAS. H. HUGHES, St. Louis, Mo.
9. Paper by L. HARRISON METTLER, Chicago, Ill.
10. Medical Aspect of Crime, JNO. C. LE GRAND, Anniston, Ala.
11. Necessity of Reform in Medical Expert Testimony, DANIEL R. BROWER, Chicago, Ill.
12. Paper by SAMUEL AYERS, Pittsburgh, Pa.
13. Remarks by J. J. M. ANGEAR, Chicago, Ill.
14. Proposed Regulation of Medical Expert Testimony, A. WALTER SCITER, Herkimer, N. Y.
15. Remarks by FREDERICK PETERSON, New York City.
16. Expert Testimony in Disputed Cases of Inebriety, T. D. CROTHERS, Hartford, Conn.
17. Remarks by HAROLD N. MOYER, Chicago, Ill.

MEDICAL ASPECTS OF CRIME.

18. Discussion opened by DANIEL R. BROWER, Chicago, Ill.
- Topic: Some of the Physical and Psychical Peculiarities of the Habitual Criminal.

19. Physical Criminology or Symptoms of Crime. ARTHUR McDONALD, Washington, D. C.
20. Paper by THOMAS D. COLEMAN, Augusta, Ga.
21. The Physiology and Psychology of the Congenital Criminal. JAMES WEIR, Owensboro, Ky.
22. Medical Aspects of Crime in Relation to Insanity and States of Mental Enfeeblement. H. E. ALLISON, Mattewan, N. Y.
23. Medical Theories of Crime. W. O'DANIEL, Bullards, Ga.
24. Crimes Prevention in the Large Cities. G. W. INGRAHAM, Binghamton, N. Y.
25. Paper by ALBERT C. CORR, Corlinville, Ill.
26. The Physician and Criminal. J. B. RANSOM, Dannemora, N. Y.

OTHER PAPERS.

27. Medical and Surgical Treatment of Epilepsy, FREDERICK PETERSON, New York City.
28. Modern Methods of Treating Epilepsy. W. X. SUDDUTH, Chicago, Ill.

51. Electricity and Light as Therapeutic Agents. W. S. WATSON, Fishkill-on-the Hudson, N. Y.

W. J. HERDMAN, Secretary.

Section on Materia Medica, Pharmacy and Therapeutics.

TUESDAY, MAY 5 AFTERNOON SESSION.

1. Address of Chairman The Practice of Pharmacy as a Liberal Profession, F. E. STEWART, Detroit, Mich.
2. How Much Pharmacy should be Taught in Medical Colleges? G. WALTER BARR, Keokuk, Iowa.
3. The Teaching of Materia Medica and Therapeutics in Our Colleges, DANIEL R. BROWER, Chicago, Ill.
4. Methods of Education in the Departments of Materia Medica and Therapeutics, H. W. ROGERS, Cleveland, Ohio.

Discussion: Opened by WARREN B. HILL, Milwaukee, Wis.

WEDNESDAY, MAY 6 MORNING SESSION.

5. Serum Therapy,
 - (a) Principles of Serum Therapy. Contribution from the Harvard Laboratory, HAROLD C. ERNST, Boston, Mass.
 - (b) Theory of Serum Therapy. Contribution from the Bacteriologic Laboratory of the City of Philadelphia, B. MEAD BOLTON, Philadelphia, Pa.

- (c) The Antitoxins, What They Are and How They are Prepared. Contribution from the Bacteriologic Laboratory of the University of Pennsylvania.

JOSEPH MCFARLAND, Philadelphia, Pa.

- (d) Serum Therapy in Diphtheria, EDWIN ROSENTHAL, Philadelphia, Pa.

- (e) Antitoxin in Tetanus. Contribution from the Pepper Laboratory of Clinical Medicine.

S. S. KNEASS, Philadelphia, Pa.

WEDNESDAY, MAY 6—AFTERNOON SESSION.

6. Serum Therapy—Continued.

- (f) Tubercle Antitoxin, or Antituberculin,

PAUL PAQUIN, St. Louis, Mo.

- (g) Protonuclein.

Discussion opened by GEO. L. STERNBERG, Washington, D. C.

THURSDAY, MAY 7—MORNING SESSION.

7. Suggestive Therapeutics.

- (a) Attention, a Factor in Therapeutics,

G. V. I. BROWN, Duluth, Minn.

- (b) The True and Tenable Ground of Suggestive Therapeutics, J. B. TAYLOR, Bloomington, Ill.

- (c) Practical Uses of Suggestive Therapeutics,

WILLIAM LEE HOWARD, Baltimore, Md.

Discussion.

THURSDAY, MAY 7—AFTERNOON SESSION.

8. Emergency and Stimulating Rations,

CHARLES E. WOODRUFF, Fort Sheridan, Ill.

9. Prescription Writing and Pharmacy, as Practiced in Our Large Hospitals and Dispensaries,

HENRY R. SLACK, La Grange, Ga.

10. Proprietary Medicines, O. D. BENSON, Des Moines, Iowa.

FRIDAY, MAY 8—MORNING SESSION.

11. A New and Improved Hypodermatic Case,

ELMER LEE, Chicago, Ill.

12. Guaiacol Carbonate.

V. W. GAYLE, Kansas City, Mo.

13. Discussion of the United States Pharmacopeia.

14. Report of Committee on Chairman's Address.

SOCIETY NEWS.

Mitchell District Medical Society. The 49th semi-annual meeting of this Society will be held at Shelbyville, Ind., June 29 and 30, 1896. An elaborate program is being arranged containing papers by some of the most eminent men in the profession. The Shelby County Medical Society which has more than a State reputation as entertainers, is preparing to entertain the Society handsomely. The program will be issued about June 15.

The Ohio State Pediatric Society will hold its annual meeting at Columbus on Wednesday, May 27. Those who have papers to present should at once communicate with the Secretary, Dr. Geo. M. Clouse, of Columbus, giving title of paper. The other officers of the Society are: President, Dr. S. W. Kelley, Cleveland; Vice-President Dr. J. P. West, and Chairman of Council, Dr. J. M. Dunham, of Columbus. Any regular physician who is particularly interested in pediatrics and a worker therein is eligible to become a member of this young and growing Society. Drones not wanted.

Illinois State Medical Society. The citizens of Ottawa, Ill., will be pleased to entertain at their homes all those who may attend the meeting of the Illinois State Medical Society, May 19, 20 and 21. In order to avoid confusion it will be necessary for those who wish to avail themselves of this offer to notify Dr. J. R. Hoffman, Secretary of the Committee of Arrangements. It will be impracticable for us to provide entertainment for those who do not notify us in advance of the meeting.

COMMITTEE OF ARRANGEMENTS.

Next Meeting of the Association. To the Editor:—At a meeting of Philadelphia County Medical Society held April 15, a committee was appointed to urge the members of the AMERICAN MEDICAL ASSOCIATION to favor the holding of a semi-centennial celebration of its organization. The Society also instructed its delegates to invite the ASSOCIATION to hold the

meeting of 1897, which will be the semi-centennial, in the city of Philadelphia. Will you kindly give in the *JOURNAL* publicity to this announcement and advocate editorially the acceptance of the invitation to Philadelphia.

Yours very truly,

JOHN B. ROBERTS,
JAMES C. WILSON,
WILLIAM M. WELCH,
Committee.

Philadelphia, April 17, 1896.

The Medical Society of the State of Pennsylvania will hold its forty-sixth annual meeting at Harrisburg, Pa., May 19 to 21, inclusive. The large number of papers and names of the writers assure a very "useful" meeting; the members will be well rewarded for their attendance. The Hall for the Exhibits is one of the finest in the city, a new building well lighted and with plenty of space for exhibitors. The exhibit will be confined to pharmaceutical articles recognized by the United States Pharmacopeia. It is the first of the kind held by any State medical society; perhaps we may say, by any medical society in the country. While these things of profit have been provided, those of pleasure have not been forgotten: receptions have been provided for so that the medical man and his wife can meet the citizens of the capital city of Pennsylvania. This will be the fourth time that the State Society has visited Harrisburg and some of the Committee of Arrangements have been on all four committees. No matter how many come, we can accommodate all.

Medical Association of Missouri.—Announcement. The Thirty-ninth Annual Meeting of the Medical Association of Missouri, will be held at the Court House in Sedalia, Mo., on Tuesday, Wednesday and Thursday, May 19, 20 and 21, 1896, convening at 10 o'clock, A.M., on Tuesday, the 19th. Sedalia is easily accessible from every section of the State, and we expect the largest attendance ever had by the Association. You are cordially invited to attend. We take pleasure in advising you that a rate of a fare and one-third for the round trip, upon the certificate plan from points in Missouri, has been granted to delegates; provided that not less than 100 tickets shall be certified to by the secretary. Take a certificate from the ticket agent when you buy your ticket, and if you travel over more than one road take a certificate for each ticket purchased. Present your certificate to the secretary as soon as you arrive. Do not purchase your ticket earlier than three days prior to the opening day of the meeting. The following roads have agreed to give the one and one-third fare on round trip tickets, viz: All roads belonging to the Western Passenger Association whose lines extend into Missouri; also the M. K. & T. Railway; and the Kansas City, Fort Scott and Memphis Railway, south of and via Clinton; Sedalia, Warsaw & Southern. The leading hotels will give reduced rates.

President, C. Lester Hall, M.D., Kansas City, Mo.: Secretary, Frank R. Fry, M.D., St. Louis, Mo.

W. A. Evans, E. F. Yancey, A. F. Dresel, Committee of Arrangements.

Sedalia, Mo., April 17, 1896.

National Confederation of State Medical Examining and Licensing Board.—The sixth Annual meeting of this organization will be held in Room No. 1, Hotel Aragon, Atlanta, Ga. (which offers reduced rates), Monday, May 4, 1896, at 10 o'clock A. M. The following program will be carried out, namely:

1. Introductory Remarks by the Vice-President.
2. Report of Committee on revision of the Constitution and By-Laws.
3. Discussion and action thereon.
4. Report of the Secretary.
5. Annual Address of the President.
6. Address by James Russell Parsons, Jr., Esq., Albany, Director of Examinations, University of the State of New York: Preliminary Education, Training and Practice in New York.
7. Paper—The Limitations of the Standard of Modern

Educational Requirements, as Determined by State Medical Examining Boards, by Joseph M. Mathews, M.D., Louisville, Ky.

8. Paper—(Subject to be announced), by William S. Foster, M.D., Pittsburg, Pa.

9. Some obstacles to an Inter-State recognition of a State License to practice Medicine, with suggestions for their removal, by Charles McIntire, M.D., Easton, Pa.

10. Miscellaneous Business.

11. Election of Officers.

The objects of the Confederation, though purely of an advisory nature, are to discuss questions that pertain to State licensure in medicine, with a view to a comparison and improvement of methods, a collection and dissemination of information on the subject, and to consider any and all propositions that have for their purpose the advancement of the standard of medical education in the United States. The officers of the Confederation, therefore, beg to extend a cordial invitation to members of State Examining Boards, and all ex-members of State Boards, and especially to every physician and educator who is friendly to the objects sought, to attend the meeting and participate in the proceedings.

Please indicate by a note to the Secretary whether you will attend.

By order of the Executive Council.

B. M. GRIFFITH, Secretary.

Springfield, Ill., April 1, 1896.

PUBLIC HEALTH.

Sale of Second-hand Clothing Not a Nuisance.—The supreme court of North Carolina declares, in the case of *State v. Taft*, Feb. 25, 1896, that the sale of second-hand clothing is not a nuisance in itself, but is, on the other hand, a lawful business. As a consequence, it holds that the commissioners of towns authorized to pass laws for abating or preventing nuisances of any kind, and for preserving the health of the citizens, can not pass an ordinance making it unlawful for any person to import into the town, for the purpose of selling or offering for sale, any second-hand clothing, cloth or bed furniture. But it does say that the town authorities would have the right to compel fumigation and disinfection of second-hand clothing, and that they might require proper assurances, before such articles were imported or offered for sale, that they have not been bought in or brought from markets or places where epidemics of contagious or infectious diseases were or had been recently prevailing, or they might prohibit the further sale of such stocks from which articles had been sold and had communicated disease. In the case of *Rosenbaum v. City of Newbern*, decided March 10, 1896, the same court holds valid a city ordinance which imposes a fine of \$50 for selling or offering for sale second-hand clothing without having it disinfected by fumigation, and by paying a price fixed according to the nature of the garment, as set forth in the ordinance, for the city authorities to do the fumigating. Here the court says that the right to buy or sell such articles is not an absolute one, but may be subjected to such restrictions, by the lawmaking power intrusted with the authority, as may be necessary to make its exercise consistent with the safety and security of others.

Possible Co-existence of Smallpox and Cowpox.—Dr. S. L. Abbott, of the Massachusetts State Board of Health, has had a singular case, which, as given in the *Boston Medical and Surgical Journal*, for March 19, tends to confirm the generally accepted theory of the non-identity of variola and vaccinia: "I was summoned one day to a young woman who was said to be a little indisposed, but on account of the appearance of a slight eruption it was thought expedient to call in a physician. I found her up and dressed, her symptoms not having been severe enough to keep her in bed at any time. All that I could see was a few, perhaps half a dozen, abortive pustules of varioloid. She did not feel at all sick. Its character was unmistakable, however. At the time there was a moderate epidemic of smallpox in the city, kept under control by general vaccination.

The patient had been vaccinated in childhood, which accounts for the mildness of her attack. In the same room with her was a nursing infant, six months old, which had not been vaccinated, and which I vaccinated at once. The vesicles of vaccinia developed normally, and were of such a perfect type that on the eighth day I took virus from the arm and vaccinated two interesting little girls about five and seven years old who had never been vaccinated before, the only children of a poor widow. The following day, on visiting the infant from whom I had taken the vaccine matter I was horrified to find a commencing eruption of smallpox. This developed rapidly, became very full and finally confluent—the pustules about the mature vaccine vesicles crowding upon them and entirely overwhelming them, so that they did not dry up in the usual way, but lost their individuality in the surrounding confluent eruption—and the child died in a few days. It can well be imagined that the succeeding week was not a very comfortable one for the vaccinator, who, however, succeeded in keeping his own counsel and waited for events. The vaccine development, however, went on in the vaccinated children in normal fashion, *producing perfectly normal vesicles*. In fact, it was so effectual that one more vesicle appeared in addition to those directly produced by the punctures of the vaccine quills, and close to them. No constitutional disturbance occurred, and the vesicles dried up in the usual way. There was no evidence whatever of variolous infection. A little consideration shows that the first child was vaccinated at a very early stage of the variolous infection, the system not being very powerfully impressed by it at the time, so that the vaccine virus was able to overcome it locally, establishing, so to speak, little islands of pure vaccinia which went to complete development before variola appeared on any part of the body. It seems to me that this case is of special value at the present time, when the claim is being made that the bacillus of variola and vaccinia is the same, and lately, in Paris, that vaccinia is nothing but attenuated variola. With regard to the former claim, if the assertion is true, the question comes up: What is the significance then of the bacillus? If the second is true, how could it happen that an attenuated virus, when planted in a soil already preoccupied by the same virus, did not develop with it and add to the intensity of its development?"

Michigan State Board of Health. The regular meeting of the Michigan State Board of Health was held at Lansing, April 10, 1896. The meeting was called to order by the President Hon. Frank Wells of Lansing, and the following members were present: Prof. Delos Pall, Albion; Dr. Samuel G. Milner, Grand Rapids; Dr. George H. Granger, Bay City; Judge Aaron V. McAlvay, Manistee, and Secretary Henry B. Baker of Lansing. The regular business of auditing bills and accounts was transacted. The Board voted to direct the Secretary to request health officers from whom no annual reports had been received for the year 1895, to make such reports immediately, in accordance with State law, or proceedings would be commenced against such delinquent officers. Reports by Attorney Gen. Judge McAlvay and the Secretary of the Board, who read a letter from Health Officer Duffield, showed that the report of the health officer of Detroit was being made out and might be expected in a few days. One of the most important and interesting subjects which came to the attention of the Board was in connection with a communication from Gov. John T. Rich, which suggested that the State Board of Health communicate with the proper official at each State institution in Michigan, especially the several asylums for the insane, calling attention to the prevalence of consumption in animals and in man, the danger of this disease being spread from animals to man by means of the milk supply, and suggesting a plan whereby each institution could Pasteurize or in some way sterilize all the milk used. The Secretary mentioned that the subject of the Pasteurization of milk was being taught at the Agricultural Experiment Station, at Madison, Wis. If necessary, some person might be sent to this school for instruction, who could return and teach the subject in this State. He mentioned that Mr. Grosvenor is said to be Pasteurizing milk for sale in Monroe, Mich., and that a company in Northville has been thus preparing large quantities of milk for sale in Detroit. The Board directed the Secretary to send to the several State institutions communica-

tions which shall cover the Governor's suggestions for the sterilization of the milk supply for the inmates of State institutions. In connection with this subject the Secretary read an item relative to a farmer who lost two head of cattle from tuberculosis. Later the disease developed in the farmer's family, consisting of six members, all of whom, together with two attendants, have since died with consumption. The difficulties in the way of inducing the people generally to act on this subject are many, but the Board recognizes the fact that it is of very much greater importance that the milk supplies of cities and villages should be sterilized so as to be free from tuberculosis and typhoid fever germs, than it is to protect only the inmates of State institutions. The Board directed its Secretary to prepare for publication and general distribution a forcible statement of the facts and dangers from infected milk, and methods for the sterilization of the public and domestic milk supplies. The Secretary made a special report upon the distribution of the Board's leaflets and pamphlets relative to communicable diseases, to school teachers, county school commissioners, city school superintendents, and in a number of instances to pupils in high schools. This report showed that there are about 16,000 teachers in Michigan, and that about 20,000 sets of such publications had been sent out. This distribution of leaflets was in compliance with Act 146, laws of 1895, which requires the Board to supply data and statements bearing upon the modes of spreading and the best methods for the restriction and prevention of the dangerous communicable diseases, which subject is required to be taught in every public school in Michigan.

Health Reports.—The following health reports have been received in the office of the Supervising Surgeon-General Marine-Hospital Service:

SMALLPOX—UNITED STATES.

Michigan: Bay City, Ionia, Marine City, April 4 to 11, smallpox reported; Detroit, April 11 to 18, 1 case, 1 death.
Louisiana: New Orleans, April 4 to 11, 74 cases, 23 deaths.
Alabama: Mobile, April 5 to 12, 2 cases, 1 death.
Ohio: Dayton, April 9 to 16, 4 cases.
Kentucky: Paducah, April 7 to 14, 5 cases.

SMALLPOX—FOREIGN.

Dublin, March 28 to April 4, 1 death.
Alexandria, March 5 to 11, 1 death.
Amsterdam, March 28, to April 4, 1 case.
Cairo, March 5 to 11, 2 deaths.
Cardiff, March 28 to April 4, 1 case.
Cienfuegos, March 29 to April 5, 1 death.
Corunna, March 21 to April 4, 3 deaths.
Genoa, March 28 to April 4, 2 cases, 1 death.
Hamburg, March 28 to April 4, 3 cases.
London, Eng., March 21 to 28, 33 cases.
Odessa, March 21 to 28, 14 cases, 3 deaths.
Prague, March 21 to 28, 14 cases.
Santiago de Cuba, April 4 to 11, 2 deaths.
St. Petersburg, April 14 to 21, 17 cases, 4 deaths.
Tuxpan, March 21 to April 4, 2 deaths.
Warsaw, March 14 to 21, 1 death.

CHOLERA.

Alexandria, March 5 to 11, 2 deaths.
St. Petersburg, March 14 to 21, 1 case.

YELLOW FEVER.

Santiago de Cuba, April 4 to 11, 1 death.
Rio de Janeiro, March 7 to 14, 231 deaths.

NECROLOGY.

JAMES WEST ROOSEVELT, M.D., of New York city, died unexpectedly from pneumonia on April 10, aged 38 years. He was the son of the late S. Weir Roosevelt, a nephew of James A. Roosevelt and a cousin of Theodore Roosevelt, President of the Police Board. He was an alumnus of Columbia College medical department, of the class of 1880. A widow and three young children survive him. He was a member of the Academy of Medicine, the Medical Surgical Society, the Practitioners' Society, the Pathological Society, and was attending physician at Bellevue, Roosevelt and Seton Hospitals. He was a man of versatile ability, a graceful yet forcible writer, and a specialist in affections of the thoracic viscera.

MARIE PHILIBERT CONSTANT SAPPEY, M.D., of Paris is

deceased. *Science* thus speaks of him: "The anatomist, Dr. P. C. Sappey, died on March 14, at the age of 86. He was the author of important researches on the respiratory apparatus of birds, on the lymphatics and on other subjects, but is best known for his great work on 'Descriptive Anatomy,' which was begun in 1847 and completed in 1863." His second edition, revised throughout, was published from 1867 to 1872 in four volumes. He also wrote upon special subjects, such as the anatomy of the human urethra and the pathology of hepatic cirrhosis.

JAMES P. PARKER.—The editor of the *General Practitioner* announces the decease of Dr. James P. Parker, of St. Louis, who was editor and proprietor of the *Annals of Ophthalmology and Otology* since 1890. He was born forty-two years ago on a farm near Marshall, Ala., and after receiving such education as the county schools afforded, he began the study of pharmacy and received his degree in this branch of medicine in 1883. He then entered Jefferson Medical College and graduated with the degree of M.D. in 1886.

Dr. MARY E. OSBORN, died April 5 at the Jewish Hospital, Cincinnati, aged 40 years. She graduated at the Philadelphia Woman's College in 1883, and has filled several important positions of trust with conscientious fidelity, among which were the superintendency of the Aultman Hospital at Canton, Ohio; Preston Retreat, Philadelphia, etc. The cause of death was multilocular, gangrenous ovarian cyst. Dr. Osborn was one of the best educated and foremost of America's women practitioners.

JOHN F. MCKENZIE, M.D., of Leroy, Ill. (Louisville Medical College 1874), April 14. The McLean County Medical Society met and passed appropriate resolutions.—Alfred Miller, M.D., of New Ulm, Minn., at Berne, Switzerland, March 3. He was surgeon U. S. Vol., from 1861 to 1864, and stationed at Fort Ripley.—A. H. Williams, M.D., of Hendersonville, Tenn., shot from ambush while on his professional round of visits, April 11.—F. H. Conger, M.D., of Prairie du Sac, Wis. (College of Physicians and Surgeons, N. Y., 1872), April 7.—Thos. M. Hess, M.D., of Berwick, Ill. (Rush Medical College 1871), April 9, aged 77.—W. C. Tappan, M.D., of Baltimore, Md., April 10, aged 78.—S. L. Brown, M.D., of David City, Neb., April 11, aged 80.—W. K. Mattern, M.D., Coroner's Physician of Philadelphia, Pa. (Jefferson Medical College 1882), April 16.—Chester A. Hard, M.D., of Los Angeles, Cal. (Ind. Med. College 1845), April 18.

BOOK NOTICES.

History of the Life of D. Hayes Agnew, M.D., LL.D. By J. HOWE ADAMS, M.D. Philadelphia and London: The F. A. Davis Company, Publishers. 8vo, cl., pp. 376.

The Chicago office of the F. A. Davis Company are making a clearance sale, at a greatly reduced price, of the biography of this well-known Philadelphia surgeon. The volume contains the story of the life of Dr. Agnew, with that of the ancestral records of the Agnew family. The story of the early professional life of Dr. Agnew is full of suggestiveness and encouragement to those for whom life seems a bitter mockery and a failure generally. Lives of men who have distinguished themselves in any branch of professional learning are always interesting and instructive, but doubly so when the subject of the biography has such a brilliant career as the late Dr. Agnew.

The International Medical Annual and Practitioner's Index for 1896. Edited by a corps of thirty-seven department editors, European and American, specialists in their several departments. 728 octavo pages. Illustrated. \$2.75. E. B. Treat, Publisher, 5 Cooper Union, New York.

This fourteenth edition of the well-known year book has been carefully prepared, and brought quite up to date. It is doubtless one of the first of the annuals to have articles on "remedial cycling" and the new photography, each of which topics is managed with knowledge and ability.

MISCELLANY.

Mineral Springs.—There are 1,044 in France that have been exploited, and the number of visitors in 1894 was over six hundred thousand.

The 4th International Congress of Criminal Anthropology will be held at Geneva, Switzerland, August 24 to 29. All articles must be in French.

Rommelaere Institute.—The government of Belgium has just received a bequest from M. Renier, of \$400,000, to found a medical college to be called the Rommelaere Institute.

Female Medical Students.—Out of a total of 1,004 students in Switzerland 304 are women, and they rank high in their studies.

A New Means of Livelihood.—A Paris daily recently contained an advertisement for a person of fine and distinguished physique, to attend in the waiting room of a physician, in the capacity of a "cured patient."

Are Venereal Diseases a Cause for Divorce?—This question was discussed at a recent medico-scientific meeting at Bonn, and decided in the negative, but the Russian periodical, *Wratch*, asserts that the consequences are so serious that the marriage should be dissolved at once upon their appearance.

The Centennial of the Societe de Medecine at Paris, was celebrated March 22, with great élat. A century of labors for humanity and science is a grand record, and the AMERICAN MEDICAL ASSOCIATION, but half as old, will send its greetings and congratulations to this noble daughter of the Revolution.

New Method of Injecting Serum.—Recent experiments with rabbits have shown that if the antistreptococcus serum is injected all around a patch of erysipelas, the lesion is confined within it and heals rapidly. The quantity used was only $\frac{1}{4}$ c.c. The same quantity injected elsewhere had no effect.—*La Semaine Médicale*, April 1.

Chemical Warming Oven.—The *Therap. Woch.*, March 29, describes a new apparatus that holds vessels, cups, etc., filled inside with sodium acetate, which has the property of retaining its heat almost indefinitely when once heated. Boiling water set in the apparatus was found at 150 degrees three hours later. It is designed to keep food, etc., warm for invalids, infants, etc.

Medical Experts.—Some of the medical journals of France and Belgium are urging the formation of a medical corps, to serve as medical experts in court, with a special medical and legal training for this end, which requires knowledge and talents of a high order, and should be suitably dignified and remunerated. Germany has long had a court officer of this sort (Gerichtsarzt).

Pocket Full of Spoons.—A physician recently appeared at a meeting of his medical association in this condition. He stated that he had accumulated them at the houses of his patients and measured their capacity, which he found different in every case, ranging from two-thirds to three times the standard capacity. One teaspoon held exactly five times as much as another. He had brought them to serve as a warning to his colleagues in ordering their medicines.

The Sero-therapeutic Tuberculous Truce.—Bernheim has succeeded in arresting the progress of tuberculosis with forty to sixty inoculations of a serum he prepares from human Koch bacilli, injected for five or six months into animals. When this tuberculous truce, as he calls it, is secured, he sends the patient to some fresh air cure or sanitarium to maintain this improvement, and strengthen the reserve forces of the organism.—*Union Médicale*, March 28.

The Roentgen Ray as a Moral Agent.—The *Union Médicale*, March 28, reports the case of a young woman who applied for an operation on account of pains in her arm, as she was convinced

that there was some abnormal condition of the bone. The surgeon diagnosed the case as the effect of some slight traumatism on a hysterical subject, and by taking a photograph of the arm proved to her that it was perfect. Once convinced of this, the patient left entirely cured.

Causes of Migraine or Periodic Headache.—Dr. Marcus, of Pyrmont, announces the discovery that the periodic headaches he has suffered from for forty years are directly due to changes in the atmospheric pressure. He has watched the advent of his attacks and those of others, and finds them always coinciding with a variation in the pressure, which is not always accompanied by changes in weather, but is always confirmed next day by the official weather bulletin. It seems to depend on the rapid fluctuations of pressure, and therefore he asks physicians who reside in localities where the atmospheric pressure is more stable, to investigate the subject, and possibly discover some way in which chronic sufferers may find relief.—*Therapeutische Wochenschrift*, March 29.

High Class Journalism.—We clip the following from the *New York Medical Record*: "The AMERICAN MEDICAL ASSOCIATION—What is it? A correspondent asks for information as follows: I see that the AMERICAN MEDICAL ASSOCIATION will meet in Atlanta soon. Can you give me any data on the subject or refer to any one who can—how large a society is it, date and place of meeting? I am especially interested in Jenner and vaccination and I would like to present some matter to the society, if it is a large society and worthy of the effort."

The foregoing inquiry shows the state of imbecility to which a presumably healthy brain may come when its possessor depends for information solely on the poor old *Record*.

Defective Legislation as to the Supply of Anatomic Material.—The *General Practitioner* calls attention to the troubles that are liable to arise from "shy legislation" on behalf of a proper study of anatomy. "The Medical College of Des Moines, Iowa, which is the medical department of the Drake University, has recently become troubled over the manner in which it procured bodies for dissection. Corpses were recently shipped from Omaha to this college and several arrests followed. It seems that our western colleges are particularly unfortunate in this respect. The success of the present session of the Topeka Medical College, located at Topeka, Kas., has been almost destroyed through troubles of a similar character to that mentioned above. Some legitimate provision should be made looking to the procuring of dissecting material for all colleges and thus avoid the sensational exposures which have followed each other during the past winter."

Sun Sanitarium.—The *Semaine Médicale*, April 1, describes the Rikli sanitarium in the mountains near Trieste, where the patients are kept out of doors, and exposed to the sun, wind and rain, in complete nudity, the head alone protected. The location of the institution is very beautiful, elevated, and secluded, with high walls separating the different parts of the large park. Commenting on the alleged credulity of the Germans, the writer adds that a hypnotizer of some fame was recently summoned from Dresden to Berlin, to treat an officer, général de brigade, in a large hospital there, for acute myelitis, under the eyes of the superintendent, and in spite of his protests.

A Reckless Midwife Committed for Manslaughter.—According to the *Press and Circular*, a midwife has recently been committed for manslaughter at the coroner's court, Sheffield, Eng., for attending a case of labor after having been warned against doing so. She had previously attended a case where death took place from puerperal fever, and four days after this she attended the woman whose death, also from puerperal fever, became the subject of inquest.

Second Pan-American Medical Congress.—The *Escuela de Medicina*, Mexico, February 15, announces the appointment of the

committee having this important enterprise in charge: President, Dr. Carmona y Valle; Vice-President, Dr. Lavista; Secretary, Dr. Licéaga. The date has been fixed for the 16th, 17th, 18th and 19th of next November, with an inaugural, a closing and an extra day devoted to science. Spanish, English and French are the official languages. It is hoped that there will be a large representation of "medicos" from the United States and Canada, as well as from the entire western continent. Dr. Lavista is the editor of the new publication of the Museo Anatómico-Patológico, which has just been inaugurated by the President of the Republic with much ceremony, and owes its existence to Dr. Lavista's efforts. He is also president of the Academia de Medicina.

The Life Insurance Companies on Urinalysis.—According to the *Medical Examiner*, March, one of the large New York companies has arranged to have all microscopic examinations of the urine of applicants made by expert microscopists, who are appointed for this purpose in various parts of the country. It has been ascertained that microscopic examinations are sometimes made when unnecessary, and where the cases would have been declined without them. It has also been found that reports of microscopic examinations are sometimes made by those who are so evidently unprepared to do the work needed, that for all practical purposes they are of no value. "This action," says the *Examiner*, "is a practical illustration of the importance of that which we have often urged upon both the medical examiners and medical colleges, namely, to be so prepared that, when asked to do that which legitimately belongs to their sphere of duty, they will not be found wanting. If medical examiners had been prepared to do this work, there is not a shadow of doubt but that they would still be doing it for this company. If there is still a desire to make microscopic examinations on the part of medical examiners, the common sense view of this matter is to prepare themselves for the work. Those who are prepared, and show companies that they are, will undoubtedly be retained. Colleges should see that their graduates are fitted for microscopic work before they certify that they are, by the issuance to them of a diploma."

The Anti-vivisection Movement in Massachusetts.—In the issue for April 10 of *Science* is a condensed paragraph regarding the action taken by the friends of modern methods of physiologic study: "At a postponed hearing on vivisection before the house committee of judiciary of Massachusetts, the proposed legislation against vivisection was opposed by Profs. Bowditch, Theobald Smith and J. J. Putnam, of Harvard University; Prof. Hodge of Clark University; Prof. Wilcox, of Wellesley College; Prof. Sedgwick, of the Massachusetts Institute of Technology, and others. President Eliot is reported by the *Boston Transcript* to have said that in the last twenty-five years, during which experiments in physiology had been conducted in Harvard, not a single instance of a student bringing any complaint of cruelty against the work done in the physiologic laboratories had ever come to the knowledge of the corporation. There was no abuse of vivisection in Massachusetts. The men whom this bill indirectly accused of cruelty to animals were the most humane, merciful, clear-sighted men in the community, devoted, year after year, to the most humane occupation now existing in the world. Their profession showed in their faces, and he appealed to the members of the committee to know whether they thought that the men who had appeared before them could be guilty of the charge implied by the application for such legislation."

Jennerian Anniversaries. We learn from the *British Medical Journal* that a committee has been formed in Berlin for the celebration of the Jenner centenary on May 14. Among the members are Profs. Virchow, R. Koch, von Leyden, Von Bergmann, Gerhard, König and others. The program includes an exhibition of portraits, medals, old and new instruments, writ-

ings, etc., bearing upon Jenner's great discovery, and also a festive gathering on the day itself, intended not only to "honor the benefactor of the universe," but to protest against the anti-vaccination agitation which is constantly going on. The *Brooklyn Medical Journal* for April announces a banquet-celebration that has been appointed for May 14, 1896. The *Journal* says: "On Thursday, May 14, the Medical Society of the County of Kings will celebrate the centennial anniversary of the first vaccination of the cowpox as a protection against the most terrible disease which ever afflicted the human race. Though the plague was more deadly, it only visited the civilized world at long intervals, but the smallpox was always present, destroying annually nearly a million people, and the best authorities agree that during the eighteenth century no less than 45,000 people died from the dread disease in Europe; while in some portions of Asia cities were actually abandoned by their inhabitants to escape the disease which spared no one; and in America more than half of the afflicted Indian tribes were sacrificed to its ravages. When we contrast the eighteenth century with the nineteenth all will admit that the Entertainment Committee can not go too far in making the anniversary an event which will honor not only the name of Jenner and his work, but also the medical profession of the fourth city of the Republic."

Right to Unmutilated Body of Husband.—An entirely new question to the courts of New York, and one of considerable interest, was decided by the supreme court, appellate division, in the case of *Foley v. Phelps*, Feb. 21, 1896. The plaintiff's husband fell through an elevator shaft in a building in New York city, and was taken, in an unconscious condition, to the Bellevue Hospital, where he died three hours after admission. She applied, it is alleged, at the hospital for his body, and begged those who were in charge of it not to allow or permit an autopsy to be performed, and gave notice that she would immediately send an undertaker for the body, to remove it to her home, where it would be prepared for burial. Notwithstanding this, she charges that the defendant, without her knowledge or consent, procured, assisted, aided and abetted in performing an autopsy on her husband's body. These allegations, the court says, clearly establish an unlawful act, for while the criminal law neither gives nor recognizes any right to institute a civil suit for damages, still it incontestably determines the wrongful nature of the act complained of, and a civil action will lie, and will lie in favor of the widow. Irrespective of any claim of property, the right which inhered in the plaintiff, as the decedent's widow, and in one sense his nearest relative, the court goes on to say, was a right to the possession of the body for the purpose of burying it; that is, to perform a duty which the law required some one to perform, and which it was her right, by reason of her relationship to the decedent, to perform. That right of possession, it holds, is a clear legal right, which the courts of law will recognize and protect. The right is to the possession of the corpse in the same condition it was when death supervened. It is the right to what remains when the breath leaves the body, and not merely to such a hacked, hewed and mutilated corpse as some stranger—an offender against the criminal law—may choose to turn over to an afflicted relative. The invasion or violation of this right furnishes a ground for a civil action for damages.

The Arterio-Venous Anastomosis Discovery Anticipated by Riolan.—Dr. Folet writes to *Progrès Médical* that the late anatomic surprise given to the medical world by Drs. Debierre and Gérard is referred to by Riolan, and by him ascribed to Galen. This anticipation may, in his opinion, be recalled of record without in any wise prejudicing the originality and merit of the work of his countrymen. He says, as quoted in the *New York Medical Journal*, that these arterio-venous anastomoses were pointed out without any direct demonstration or exact

description by Riolan. The majority of authors speak of Riolan's "Encheiridium Anatomicum" (1648), without having read it, and that is the reason why Riolan has been accused of being one of the most systematically obstinate opponents of the theory of circulation. The truth is, says the writer, that Riolan's theory of the general circulation was an extremely curious and mixed one, and may be summed up as follows: There are blood vessels in which the blood circulates, the aorta and the vena cava. The blood takes a centrifugal course in the large artery, the aorta, and a centripetal course in the large vein, the vena cava. But in the medium or small blood vessels, arterial or venous, the blood is stagnant, or has a sort of slow backward and forward motion in order to nourish the tissues which it washes. The excess of the arterial wave—and here, says the writer, may be seen the coincidence between Riolan's theory and the facts pointed out by M. Debierre—passes from the large-sized artery, where it travels toward the periphery, into the large-sized vein, where it returns to the center through the anastomoses which exist between the arteries and the veins of the limbs. The existense of these anastomoses can not be denied, he says, for Galen demonstrated it and daily experience confirms it. Again Riolan wrote: "The veins have this peculiarity, that, in the limbs, they manifestly communicate with the arteries. Galen proved it, and it is so clear that we should not question it." The writer states that he has referred to the chapter in Galen's work indicated by Riolan, and that he has found nothing in regard to the subject, but in the preceding chapter he has found the following incidental passage: "The arteries which are brought together by several points with veins . . ." Riolan, then, says M. Folet, was much more explicit than Galen, whose authority he invoked. The writer states that he has called attention to the foregoing passages only because of the curious coincidence.

The Late Dr. Cheek, Medical Missionary to Siam.—The late Dr. Marion A. Cheek, of Oakland, Cal., had a romantic history, as reported in the *San Francisco Examiner*. The survivors of Dr. Cheek have a claim, growing out of his adventurous career, against the Siamese government for \$80,000, the value of 176 elephants that were once his property, but which were, it is alleged, unjustly confiscated by the government. The *Examiner* says: "The story of Dr. Cheek's adventures in the East reads like a romance. He went to Siam a missionary of the Christian religion. His knowledge of medicine stood him in good stead. He ingratiated himself into the hearts of the princes of the land as well as the lowly natives, who saw in his remarkable cure of disease an unfathomable mystery. Dr. Cheek was an American. He overlooked no opportunity to better his condition. He gained valuable concessions from the Siamese government and established the business of logging teak timber to Bangkok, the capital. The returns were so great that some of the native princes in the interior cast longing eyes upon the profits the American was turning. One of them suggested a partnership. Dr. Cheek was loath to accept the proposition, but he decided that his own welfare demanded that he join hands with the dusky prince. The Doctor had an agreement with his princely partner as to the distribution of the labor. Cheek agreed to do the actual work. He went 500 miles into the teak timber district and hired many native laborers. He likewise secured 176 elephants. The Doctor had indifferent success one season. The river was low and no logging could be done. The prince became dissatisfied. He was appeased, thought Dr. Cheek, the following year, when a double quantity of timber was floated into Bangkok. Then the trouble commenced. The government took a hand. The Doctor's partner and prince assigned his interest in the firm to the royal family. The ruling powers were becoming dissatisfied with foreign interests and their extension in Siam. The excuse was readily found for action. The failure to make a

shipment of timber in one season opened the way. The government stepped in and confiscated Dr. Cheek's plant, elephants and all. This summary action ended the Cheek logging business. Minister Barrett at Bangkok has made every effort to bring the matter to a focus. The Siamese government is said to be desirous of submitting it to arbitration. The will of Dr. Cheek has been filed and probated in Alameda County. His widow and two children now reside in Oakland. They have local counsel, who are pressing the payment of the claim to their utmost."

Unobserved Gonorrhea of the Rectum.—Dr. Wallace Johnson, of Washington, writing to the *Medical News*, March 28, considers the question of the unobserved frequency of the above named symptom. On the same subject, in the February 20 number of the *Deutsche med. Wochenschrift*, in an article by Dr. Theodore Barr, Dermatologist to the City Hospital at Frankfurt-on-Main, gives some unusual figures as to the frequency of the disease when carefully sought for. He says that from June 15, 1895, to Jan. 1, 1896, of 191 female patients with gonorrhea, 67, or 35.1 per cent., of all the cases, had gonorrhea of the rectum, as was established by microscopic examination. He thinks that the supposed rarity of the disease is owing to the fact that few cases give rise to symptoms pointing to the rectum. Few have bloody or purulent discharge from the rectum and few have pain or tenesmus. Where these symptoms are present he thinks them due to excoriations and ulcerations at the anus. Dr. Barr thinks that the cause is almost always found in a cervical gonorrhea, the secretions from which are carried into the rectum by the syringe nozzle, the thermometer or other manipulations about the anus by patients of not too cleanly habits. One of his cases developed a peri-proctitis as a complication, which afterward formed a fistula, in the discharge of which the gonococci were demonstrated.

The Dwarf Peoples of Africa.—Prof. Heli Chatelain, of the Smithsonian Institute, writes to *Illustrated Africa* the following observations respecting the wide distribution of the dwarf people of Africa. He says: "The Bushmen, or San, of South Africa belong to the same race as the pygmies or dwarfs of the Central African and equatorial forests. Their stature varies between four and five feet. Their physical appearance and their language show affinity with the Hottentots, but the relationship is very remote. The San language is poorer in morphology than the Khoi-khoi, but richer in clicks. The Bushmen, like the pygmies, are exceedingly timid, and hover, as Helots, on the skirts of Bantu settlements, whom they supply with game. The Hottentots, on the contrary, are pastoral, independent, and even aggressive. They are the terror of less audacious and less advanced Bantu tribes. Perhaps no savage people on earth excel the Bushmen as hunters; and their rock paintings show decided artistic aptitude. Both Hottentots and Bushmen are not numerous enough to resist, independently, the absorbing influence of their Bantu and European neighbors. The pygmies of Central and Equatorial Africa form, most probably, one ethnic class with the Bushmen of South Africa. Their language, however, is not yet sufficiently known to warrant the expression of an opinion as to kinship with San. They are hunters and fishermen, living in temporary grass huts of the beehive shape, and keep no domestic animal save chickens. Though culturally on the lowest scale, they are said to possess many virtues; and may, under the regenerating influence of the Gospel, develop some sterling qualities and attain prominence in certain specialties."

Proposed Adoption of the Anthropometric or Bertillon System of Identification in New York City. The Police Department of New York intend to put in operation a system of anatomic identification, similar to that in use in several European countries, and in Chicago in this country. The system derives its name from its inventor, Dr. Alphonse Bertillon, now the Chief of the

Identification service at the Prefecture of Police in Paris. He called it the Anthropometric System, but the world insists on knowing it by his name. The system depends upon a series of accurate and minute measurements of various portions of the human frame, assisted by photographs. The photographs are not merely photographs of the face. These are valuable adjuncts, but are not infallible in themselves. The rapidity with which a professional rogue can change his appearance is astonishing. Photographs of particular feature are often more accurate and decisive. For instance, it is impossible among 100,000 individuals to find two ears exactly alike, except in the case of twin brothers. But photography, as already stated, is only an adjunct. The special value of the system depends upon measurements of those bony parts of the body which undergo little or no change after maturity and can be measured to within so small a figure as to be practically accurate. These are the head, the foot, the middle finger and the extended forearm from the elbow. In addition, measurements are taken of the length, the span, the trunk of the body and the right ear. Notes are made of the color of the eyes and hair, the supposed age and nationality and of any individual marks or scars upon the body. The measurements selected are those that science has indicated as being the least changing from year to year. The success of the system depends upon three facts, which Bertillon considered of great importance, and which many years of experience have rendered indisputable: The almost absolute fixity of the human skeleton beginning at and after the twentieth year of age; the extreme diversity of dimensions which the human skeleton presents when one subject is compared with another; the facility and relative precision with which certain dimensions of the skeleton are capable of being measured. The measurements adopted were as follows:

- 1, Three body measurements, consisting of height, standing, stretched out arms, height sitting; 2, four head measurements, consisting of length of head, width of head, length of right ear and width of right ear; 3, four limb measurements, consisting of length of foot, length of left middle finger, length of left little finger, length of cubit. All these measurements can be taken in a few minutes by any ordinary operator. The instruments are simple and can be obtained in Paris at a cost of about \$11. The measurements are noted upon descriptive cards about six inches square, upon the same side of which are generally placed two photographs of the criminal, front and side view, and upon the back a record of his criminal operations, convictions, terms served, etc., and his scars and marks.

Practical Notes.

Vomiting of Pregnancy.—La Torre announced at a recent meeting of the Società Lancisiana degli Ospedali, Rome, that he had succeeded in stopping the vomiting in three cases of this kind, by means of a simple tampon of ichthyol applied to the neck of the uterus. — *Gaz. degli Osp. e delle Clin.*, March 14.

Paramyoclonus Multiplex.—A typical case of this disease which had persisted thirteen years, was recently cured in five weeks with Fowler's solution, in doses increasing from 2 to 10 drops, three times a day. It was accompanied with cold lotions and galvanization. — *La Semaine Médicale*, April 1.

Effect of Castration on Skeletal Development.—Most travelers in the Orient have noticed the tallness of the eunuchs, and Poincet has called attention to the excessive growth of the bones in cases of early castration. He has recently commented on the curious fact that the exactly opposite effect, viz., stunted growth, is produced by lack of function in the thyroid glands. — *Province Médicale*, March 28.

Loretinate of Bismuth in Ophthalmia.—The *Revue Gen. d'Ophthalmologie*, March 31, states that this substance is a better antiseptic than iodoform, as it only develops colonies in forty-eight hours, while they are found in twenty-four hours with iodoform. As an occlusive dressing for the eye, loretinate of

bismuth offers superior advantages, preventive and curative, especially in cases of phlyctenular ophthalmia, for which it really seems a specific. It can be used with other treatment, which it seems to promote. Excellent to use as an accessory in cases of ocular ulcers, diphtheria, tuberculosis and epithelioma.

Blisters.—There have been some protests to Huchard's sweeping denunciation of blisters. Matthieu asserts that in hydrarthrosis a cantharides blister is invaluable, and he also uses them in gastralgia, on a space the size of a five franc piece. Adrian thinks that if the substance were applied in the form of chloroform solution, with a little squill, no bad results would follow, which he ascribes to the use of plasters that leave some of the irritant on the skin. In veterinary practice the blister is of the greatest service. All seem to agree that they are worse than useless in broncho-pneumonia, kidney and cardiac troubles, and for children and elderly persons.—*Bulletin Médical*, March 29.

Fragments of Lead in the Eye.—Valois recommends in cases of injury to the eye from some flying fragment of shot, immediate antiseptics of the eye and vicinity; also applications of ice with antiphlogistic treatment, sub-conjunctival injections of sublimate, slight compression of the eye-ball, but above all absolute repose. Later, if there is no reaction, an expectant policy is best, but if there is, and if the fragment can be seen with the ophthalmoscope, it is to be extracted. Enucleation or exenteration is required if there are inflammatory accidents, or enucleation alone if there are sympathetic complications. If the latter persist, with a probability that the fragment is still in the orbit, curettement must follow. If the fragment is producing paralysis by its pressure on some nerve, it must be sought and removed.—*Gaz. Méd. de Liège*, April 2.

Intra-peritoneal Rupture of Ovarian Cysts.—There are about three hundred cases of these ruptures on record, and where they used to be followed by grave consequences, modern asepsis has much reduced the fatality, which was 63 in 127 cases (Nepveu, *Annales de Gyn.*, 1875). The recent cases of gelatinous effusion have all recovered after laparotomy, and Professor Lannelongue reports several cases of ruptured cysts discharging fluids and pus into the peritoneal cavity, which recovered after ovariectomy, without septicemia or drainage, showing that the pus must have been sterile. Animals inoculated with the gelatinous effusion did not show any aseptic consequences. Hence, infection need not necessarily follow the escape of the fluid into the abdomen during the operation. The *Bulletin Médical*, March 29, devotes several columns to a discussion of this subject by the Bordeaux *Société de Gynécologie*.

Progress in Electro-Therapeutics.—Professor d'Arsonval's announcement that alternating currents of great frequency and high tension exert a powerful and beneficial effect on the organism, has been verified by Apostoli, who places the patient in the center of a huge solenoid, without any direct contact with the wires. The currents circulate around him, and the results have been surprisingly successful in more than a hundred cases he has treated during the last year and half. Rheumatism and gout have been most benefited, diabetes next, but the general health in all has improved, insomnia ceases, and cheerfulness, appetite and strength return with these daily fifteen minute electric treatments. The process seems to be that all the organic transformations are facilitated and accelerated *Journal de Méd. de Paris*, March 28.

Salicylic Medication Through the Skin.—When salicylate of soda is not tolerated by the stomach, salicylate of methyl can be substituted for it in cases of acute articular rheumatism, administered through the skin. Linossier and Lannois, of Lyons, have secured fine results in this way, painting the thigh with 4 grams and covering close with an air-tight pad. The healthy skin will not absorb solids nor liquids, but it will absorb gases,

and it is to the volatile properties of salicylate of methyl that its success is due in these cases. The skin absorbed it even when it was held at some little distance, showing that it was the vapors which were taken up. Almost half of the amount absorbed was eliminated in the urine within twenty-four hours. Grease or vaselin prevented absorption. Bourget has administered salicylic acid in a salve, but he mixes it with turpentine, which irritates the surface, so that it can no longer be called a strictly healthy skin.—*Bulletin de l'Académie de Médecine*, March 28.

The Alkaloid Derived from the Areca Nut.—The *British Medical Journal* quotes Dr. Mouquet, in *Nouveaux Remèdes*, regarding the therapeutic range of the hydrobromate of arecolin. This drug has a powerful sialogogue and diaphoretic action, and markedly stimulates intestinal peristalsis in horses and other animals. It has the same properties as eserine and pilocarpine, but in a higher degree, and the indications for its use are the same. Given hypodermically in doses of two centigrams to twenty-five milligrams it is found useful in animals, especially in the treatment of intestinal indigestion. Areca nut, though largely employed in veterinary practice, is little used in human medicine. The editor of the *Nouveaux Remèdes* suggests that arecolin might be worth trying on the human subject, but it would be prudent to begin with very small doses, such as two to four milligrams. Areca nut is said to be a powerful anthelmintic, the administration of which does not require to be preceded by a purge. It can be taken in milk or in soup without any unpleasant taste being perceived.

Detroit.

THE WAYNE COUNTY MEDICAL SOCIETY at its regular meeting, April 16, had exhibited a young man by the name of Lewis, with a cardiac hypertrophy, mitral insufficiency, and possibly an aneurysm of the arch of the aorta. This individual has been exhibited before the medical class at the Fort Wayne Medical College, Ind., and also before the St. Louis and Cleveland College classes. At this time compensation seems to be fully established, and the outcome would be interesting and well worth writing up, as so many individual medical men have seen and examined this man. Delegates to the AMERICAN MEDICAL ASSOCIATION from the Wayne County Medical Society have been elected.

AT THE REGULAR MEETING of the Detroit Medical and Library Association, April 13, Dr. Frank Walker read a paper entitled, "Chronic Gastritis."

HEALTH OFFICE report for week ending April 18: Deaths under 5 years, 50, total 111; births, male 63, female 55, total 118. Contagious diseases: Diphtheria, last report 7, new cases 2, recovered 5, died 1, now sick, 3; scarlet fever, last report 25, new cases 7, recovered 11, died none, now sick 21; smallpox, last report none, new cases 1, died 1; measles, last report 1, new cases 1, recovered 1, died none, now sick 1.

Washington.

WEEKLY REPORT OF HEALTH OFFICE.—The report of the Health Officer for the week ending April 11 is as follows: Number of deaths (stillbirths not included), 112; death rate per 1,000 per annum, 21.1; death rate per 1,000 per annum for the corresponding week last year, 20.2.

INEBRIATE ASYLUM BILL.—The Senate Committee has reported adversely the bill to create a hospital for the treatment of inebriety in the District of Columbia.

ANTI-VIVISECTION HEARING.—The Senate Committee on the District of Columbia held a meeting on the 17th inst. to hear the views, pro and con, on the anti-vivisection bill. A most convincing argument against the passage of such a bill was made by Surgeon-General G. M. Sternberg, U. S. A.

MEDICAL SOCIETY.—At the regular meeting of the society, held on the 13th inst., Dr. Compton reported a case of purpura hemorrhagica; Dr. Adair, U. S. A., reported a case of

appendicitis: Dr. McCormick reported a case of cancer of the stomach and hypertrophy of the heart, with specimens; and Dr. Magruder presented two specimens of cancer of the stomach.

TO FURTHER PROTECT THE INSANE.—Mr. Woodman, of Illinois, has introduced a bill in the House providing that no insane person, or person who is alleged to be insane, whether charged with crime or otherwise, shall be incarcerated in any insane asylum or hospital in the District of Columbia, or in any of the Territories, nor shall he be detained or confined by anyone until he has been brought before a court of records and adjudged to be insane. Such insane person shall be represented by counsel.

WASHINGTON OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—The 245th meeting of the society was held on the 17th inst. Dr. Bromwell read a paper on "Meddlesome Midwifery," and Dr. T. C. Smith reported a case of fibroma of uterus distending the perineum, and presented the specimen.

Cincinnati.

THE HEALTH DEPARTMENT is examining the charges made by the barbers' union that a number of shops are using the dirty towels for many of their customers, thereby spreading disease.

THE MISSISSIPPI VALLEY DENTAL ASSOCIATION held their annual meeting in Cincinnati April 16.

A NUMBER of cases of diphtheria have developed at Glendale and an extra sanitary officer has been appointed.

A CASE of smallpox has developed at Lima, Ohio.

THE TRUSTEES of the Cincinnati Hospital have decided against the present free use of such expensive drugs as listerin, trionol, phenol, etc.

A DOZEN or MORE of the most prominent practitioners of this city have organized what is to be known as the "Doctors' Headquarters." They are to occupy the Decorative Art Building on Garfield Place, and a telephone will be placed on each floor with connections with each office, a number of the different departments of practice will be represented, and in the event of an emergency call a response will be obtained from one present should the desired physician be absent.

THE FOLLOWING CASES were presented at the Academy of Medicine last week: Dr. E. W. Walker reported a case of dermoid cyst of the kidney, removed from a young child, with recovery. Dr. Joseph Ranshof reported a case of scirrhous cancer of the kidney, successfully removed from a young man about 25 years of age. Dr. E. Gustav Zinke exhibited a specimen of a large gangrenous multilocular ovarian cyst and hematoma (will be published in full in this JOURNAL). Dr. A. I. F. Buxbaum demonstrated the new method of cocaine anesthesia by cataphoresis. He operated on a tooth which prior to anesthesia was so sensitive as to prohibit the touching of its surface, but after the application of a 30 per cent. solution of cocaine on cotton and the current applied for about fifteen minutes the pulp could be manipulated without any pain on the part of the patient.

MEMBERS who contemplate attending the AMERICAN MEDICAL ASSOCIATION can obtain tickets, sleeping car berths and all desired information by addressing Dr. G. I. Cullen, 714 West Sixth Street.

THE FOLLOWING APPOINTMENTS have been made at St. Mary's Hospital: Dr. Otis L. Cameron, to succeed Dr. Ferd Kramer, deceased; Dr. T. W. Hays, Pathologist; Dr. George B. Twitchell, assistant surgeon, and Dr. Charles R. Bush, microscopist.

THE FOLLOWING series of lectures are announced by the Young Men's Christian Association: April 8, "The Physiologic Effects of Alcohol," Dr. J. A. Davis; April 18, "Personal Purity," Dr. W. H. Taylor; April 23, "The Food We Eat," Dr. W. H. Taylor; April 30, "X Rays," Dr. S. P. Kramer.

* **THE ANNUAL REPORT** of the Cincinnati Sanitarium shows that since the establishment of the institution twenty-three years ago, 2,711 patients have been admitted, while 1,242 have been discharged as cured. This is in the ratio of about 45.81 per cent., a very fair showing when we stop to consider that a recovery of 30 to 40 per cent is considered about the average of those receiving the most judicious and careful treatment.

THE MORTALITY REPORT for the week ended Friday, April 10, shows: Membranous croup 1, diphtheria 3, erysipelas 2, measles 9, typhoid fever 5, other zymotic diseases 4; cancer 5, phthisis pulmonalis 24, other constitutional diseases 3; apoplexy 3, Bright's disease 2, bronchitis 6, heart disease 9, men-

ingitis 3, nephritis 3, pneumonia 23, other local diseases 25; deaths from developmental diseases 7, from violence 5, under 1 year 23, from 1 to 5 years 23, from all causes 142; annual rate per 1,000 21.09; deaths during preceding week 123, corresponding week 1895 97, corresponding week 1894 109, corresponding week 1893 119.

THE PUBLIC SERVICES.

Army Changes. Official List of changes in the stations and duties of officers serving in the Medical Department, U. S. Army, from April 11 to 17, 1896.

Capt. Nathan S. Jarvis, Asst. Surgeon (Willets Point, N. Y.), is granted sick leave of absence for one month and five days.

Navy Changes. Changes in the Medical Corps of the U. S. Navy for the week ending April 18, 1896.

Asst. Surgeon C. M. De Valin, ordered to examination for promotion.

Marine-Hospital Changes. Official list of changes of station, and duties of Medical Officers of the U. S. Marine-Hospital Service, for the fifteen days ended April 15, 1896.

P. A. Surgeon J. J. Kinyoun, to proceed from Washington, D. C., to Wilmington, Del., for special temporary duty, April 8, 1896.

P. A. Surgeon C. P. Wertenbaker, to proceed from Delaware Breakwater Quarantine to Wilmington, Del., for special temporary duty, April 8, 1896.

Asst. Surgeon J. A. Nydegger, granted leave of absence for two days, April 13, 1896.

Asst. Surgeon W. J. S. Stewart, granted leave of absence for six days, April 6, 1896.

Asst. Surgeon Seaton Norman, granted leave of absence for fifteen days, April 14, 1896.

Asst. Surgeon S. R. Tabb, to proceed from Richmond, Va., to Chicago, Ill., for duty, April 14, 1896.

Asst. Surgeon H. S. Mathewson, to proceed from New York, N. Y., to Boston, Mass., for temporary duty, April 6, 1896.

APPOINTMENTS.

Sherrard R. Tabb, of Virginia, and Henry S. Mathewson, of Connecticut, commissioned by the President as Assistant Surgeons, April 1, 1896.

Change of Address.

Armstrong, C. L., La Due, Mo.
Butler, G. F., from 851 Jackson St. to 794 Adams St., Chicago, Ill.
Edmonds, O. R., from St. Louis to Tina, Mo.
Henkle, C. K., from St. Louis, Mo., to Independence, Ore.

The Journal of the American Medical Association

VOL. XXVI.

CHICAGO, ILL., MAY 2, 1896.

No. 18.

ADDRESS.

DR. JAMES FANNING NOYES—1817-1896: MEMORIAL REMARKS.

Delivered before the Detroit Academy of Medicine.

BY LEARTUS CONNOR, A.B., M.D.
DETROIT, MICH.

Dr. James Fanning Noyes began his earthly career in a modest farmhouse adjacent to the town of Kingston, R. I., on Aug. 2, 1817, and closed it Feb. 19, 1896, at Providence, R. I., in the elegant home of his honored and loved nephew, Dr. Robert Noyes. Between these two dates and places Dr. Noyes wrought his part in the drama of human life. In the pursuit of knowledge and doing of work he wandered far from his beloved Rhode Island, but when the end of life drew near he returned to his kindred and left his earthly body near the spot where it was given him.

It was his to live in a period of human history surpassing all previous periods. In it the practice of medicine entered upon fields of conquest heretofore undreamed of. Accurate scientific knowledge was multiplied in all directions, and its application to medicine gave astounding results. Thus the application of the laws of optics to the study of vision gave us the ophthalmoscope, a workable knowledge of the refraction of the eye and the means for so correcting its defects as to afford incalculable good to humanity. Similar instruments of precision for the study and treatment of other organs followed, till now nearly the entire body can be seen, and much that transpires within it actually heard. The discovery of anesthesia, the study of bacteriology and asepsis have rendered the surgical exploration of every organ in the body measurably safe, thus rendering amenable to treatment many heretofore incurable diseases. The chemist, the physiologist, the anatomist, the pathologist, the microscopist, the pharmacist, the hygienist, all have contributed important elements of this wonderful age. The steam and electric railways, the steamboat, the telegraph, the telephone and hosts of other mechanic arts have opened a multiplicity of medical problems of the highest interest. All these and their associated discoveries were seen by Dr. Noyes at their inception. Truly his was an age of all ages the greatest—the ripe fruit of long working, hoping, waiting.

No study of an individual life is adequate if separated from its ancestors. Each is, in a large sense, the product of the hopes, thoughts, fears, loves, ambitions, deeds of those who have gone before. Dr. Noyes came of ancestry that protested against the infringement of their religious and civic liberties in England, and sought on the bleak shores of New England opportunity to work out their ideas of the personal responsibility of each individual directly to its Maker, and to found a State based upon these ideas. In 1634 the Rev. William Noyes, a Puritan and Nonconform-

its, emigrated from England and settled at Newburyport, Mass. In this town, in 1647, the Noyes House was constructed, and has been occupied by some member of the family to the present day. Farther down the Rev. James Noyes drew up the famous Saybrook platform, was an incorporator of Yale College and preached at Stonington, where he died in 1719.

Dr. James F. Noyes was the fifth son in a family of twelve children, eight of whom grew to maturity. One brother, Edwin, became a well-known lawyer and railway man at Waterville, Me. One brother was for some years superintendent of the Michigan Central Railway. One brother still lives on the old farm at Kingston, R. I.

James was first trained in a private school kept by his sister Susan on the farm, for the benefit of the small children in the neighborhood. When older he entered a winter school kept by his father during the winter upon the farm. Later he entered the old Kingston Academy, at Kingston, R. I., in which his brother Aziel had charge of the classical department, other departments being in charge of Christopher Comstock and Hon. Thomas B. Church, father of the celebrated artist Church. Lastly he attended the Latin School for Boys, conducted by the Rev. Thomas Vernon, long time pastor of the Congregational Church at Kingston. It thus appears that most of his school training was from members of his own family.

Ill health now compelled him to relinquish the idea of securing a college education, thus changing his life, as at subsequent periods other attacks of ill health compelled changes in his professional career. It does not appear that these attacks were of a sort dangerous to life, but only to continuous mental and physical activity. Illustrative of his father's practical way in dealing with his children the Doctor related the following: When 16 years old his father placed his son in charge of a district school. Young, unsophisticated and ignorant of teaching, he was quite disturbed at the outlook, but in the early contest between teacher and pupils the discipline of the school was maintained, while the affection of the pupils had largely increased. His father was present at the end of the term, studied the situation, and remarked to his son that he need teach no longer, but rather attend school, because he had proved that he possessed material worth educating. The wisdom of this course is evident. Many young people are not worth spending money in educating beyond the common school. All professions, including the medical, are cursed with a host upon whom good money was entirely wasted. It is a pity that they had not been tested ere entering upon professional study and turned aside into callings for which their "make up" best fitted them. The world would thus have obtained the best possible work from each, and the unfortunates been rescued from the misfortune of spending their lives, as square pegs in round holes, pinched at each corner.

In 1842 James F. Noyes began the study of medicine with Dr. Joseph Potter at Waterville, Me. Two years later he took his first course of lectures at Harvard Medical School, and after a second course at Jefferson Medical College he graduated in 1846. After some further study in New York City, he was appointed assistant physician in the United States Marine Hospital at Chelsea, Mass., under Dr. James B. Loring, late United States minister to Portugal. In the fall of this year he assisted at the first public administration of ether for surgical purposes. In 1848, during the trial of Dr. Valorous P. Coolidge, at Augusta, Me., Dr. Noyes gave evidence showing that prussic acid had been used in the murder. His position being maintained by chemic evidence, conviction of the murderer was secured. This use of prussic acid being new in this country, the case attracted wide attention. In 1849 Dr. Noyes engaged in active practice at Waterville, Me., an opening being made for him by the removal of his former preceptor, Dr. Potter, to Cincinnati, Ohio. This fact, coupled with the influence of his distinguished brother, seems to have aided him in securing at once a large and lucrative practice. This rapid introduction to a large business doubtless had much to do with so undermining his health as to compel a vacation at an early date. However, while he could endure the work he did it with all the enthusiasm and energy which he possessed. The experiences thus obtained made a lasting impression upon his mind, and the older members of the Academy can recall the frequency with which he recounted his observations of medical events which occurred "down in Maine." In 1851 he left Waterville to form a partnership with his former preceptor in Cincinnati, Ohio, and continued in active work there till four years later, when failing health compelled a rest.

This rest was spent in Europe studying ophthalmology with Albrecht von Graefe, at Berlin and Vienna. The years 1858 and 1859 he spent in Paris, pursuing the same studies. While here he made the acquaintance of the late Dr. J. Marion Sims and delighted to describe Sims' first vesicovaginal fistula operation on the continent, on a patient which had failed to obtain relief from two of the best European operators. Sims' operation was perfectly successful and laid the foundation for his subsequent popularity among the French. To Dr. Noyes, Sims' triumph was patriotic as well as personal. It compelled the French surgeons to recognize the merit of American gynecology.

In 1863 his brother, then superintendent of the Michigan Central Railway, and living in Detroit, induced him to move to that city, where he remained till his retirement from practice in 1886. While he did some eye and ear work in Maine and Cincinnati, the most was done in Detroit. He was the second regular physician to engage in this work in Detroit or Michigan. The first was Dr. Hildreth, who, after a few years' practice entered the army, settled in Chicago after the war, and finally died from an accidental overdose of medicine.

Dr. Noyes' first office was in a frame dwelling on the site of the new post-office. In a few years he purchased the southwest corner of Fort and Shelby streets, and on the Shelby side of the lot erected an office building for his exclusive use, which he occupied until he sold the property in 1886. This purchase was a fortunate investment, as he paid \$9,000 and sold it for \$45,000. During his holding he received a steady income from

the rent of the dwelling-house and had his office and lodgings free.

The conditions under which he began practice at Waterville, Me., Cincinnati, Ohio, and at Detroit were all most favorable to his securing immediate and lucrative practice. Those at the two former places have already been noted. In Detroit, in addition to his brother, who occupied a high business and social position, he had cousins, W. B. and B. B. Noyes, then leading hardware merchants, and Miss Seraphine Noyes, a leader in the intellectual and social life of the city. These were pleased to acquaint their friends with the accomplishments of their distinguished relative and to introduce him to the leaders in business and society. On the organization of the Detroit Medical College in 1869 he was elected Professor of Ophthalmology and Otology, a position which he held for ten years. His record as a teacher is familiar to some of the present members of the Academy, to his students during those years and to many members of the profession. He was a member of all the local and general and medical organizations which were in any way related to his own professional life or that of his associates, viz, the Detroit Academy of Medicine, the Detroit Medical and Library Association, the Michigan State Medical Society, the AMERICAN MEDICAL ASSOCIATION, the American Ophthalmological and Otological Societies, the American Association for the Advancement of Science, the Pioneer and Historical Society of Detroit, and the Rhode Island Historical Society. He was an honorary member of State medical societies which he visited during his travels, viz., the Ohio, the Rhode Island, the Maine, and the Texas Associations. He was a Mason, and a member of the Detroit and Grosse Pointe Clubs. In 1872 he was president of the Detroit Academy of Medicine. On its organization he was elected president of the Detroit Cremation Society and signified his faith in this method of disposing of the dead by directing that his own body be cremated. He was not a prolific writer, but papers from his pen are quoted in the volumes of the *Boston Medical and Surgical Journal*, the *Detroit Review of Medicine and Pharmacy* and the transactions of the several societies to which he belonged. The published discussions of the Detroit Academy of Medicine during the period of his active practice contain frequent records of his views on a great variety of topics in all departments of medicine and surgery. He was a general practitioner of superior accomplishments before he became a specialist, and never lost his interest in any department of the entire field. He introduced a method of operation for strabismus by folding the weaker muscle and stitching it until adhesions were established and the shortening became permanent.

He took an active interest in the establishment of Oak Grove Asylum at Flint, Mich., and until his death was a trustee. Last year he provided the funds for the erection of an amusement hall for the inmates, to be known as "Noyes Hall."

He donated a large amount of money for the maintenance of free beds at the Rhode Island Hospital. For many years he had supported several young people while they were being educated for positions in which they could earn their living—his idea being to make useful citizens, capable of supporting themselves, of some who would otherwise be a burden to both themselves and others. Possibly he did this to partially compensate for his never having a family

of his own. For many years he was ophthalmic surgeon to St. Mary's, Harper and Woman's Hospitals, and he took pride in doing the work.

As a physician his manners partook of the race whence he sprung and of the customs of the physicians among whom he was educated. These covered under a gruff exterior a really kind and sympathetic heart. If the patient gave instant attention and unquestioning obedience the Doctor was a most delightful person. To other patients his words and acts as well as manner were intended to compel a proper respect for the profession in general and himself in particular. While in general practice, Dr. Noyes gained a reputation for daring and skillful surgery, and until his death he never tired of watching surgical operations. He once told the writer that he had made a mistake in dropping general for special surgery. His mental inclination was toward mechanical rather than the abstruse problems of pathology, physiology, the action of remedies, etc. In the management of medical cases he leaned heavily upon his medical friends, just as they leaned upon him in their surgical cases.

Why he never married is not clear, as he was fond of the companionship of cultured ladies and numbered them among his firm friends. The fact explains many peculiarities of his personal and professional career.

For many years anterior to his retirement from practice he was subject to occasional attacks of heart disturbance of a nature never fully made out by the most skillful diagnosticians. These attacks were very distressing to both himself and his attendants. A little extra exertion would frequently induce them. Indiscretions in diet or smoking or extra excitement were often followed by their presence. From the account of his death it would appear that he died in one of these. He thought himself that the walls of the artery supplying the heart muscle had become degenerated. His urine contained sugar for some years anterior to death, but I do not know as the relationship between this and the heart difficulty was ever satisfactorily worked out. Certainly the heart affection long antedated the urinary abnormality. However, he retained his mental powers until the last, and his death was sudden and peaceful.

After his retirement from practice his friends noted a marked change in him. His spells of moodiness and irascibility which previously had now and then enthralled him, entirely disappeared and he became one of the brightest and sunniest of men at all times. He also became interested in the comfort and happiness of those about him. He spent much time in travel, and was one of those wise travelers which become filled with the habits of the people observed, their customs, their history, the physical characteristics of both people and country, the social, educational, political and industrial peculiarities—in short, everything which it was possible for him to learn. This large increment of his mental riches, with his judgments thereupon, he placed freely at the disposal of his friends, and in such a manner as to delight and charm. Far beyond the habit of his earlier life he seemed to have a genuine pleasure in serving friends. His personal antagonisms faded away with personal asperities of speech and manner, and his entire personality mellowed and grew steadily richer in all that pertained to a genuine manhood. His hoary head became a crown of glory, shining brighter and brighter until

his spirit took its upward flight. From this study of these 78 years of a single human life we note:

1. The stock from which Dr. Noyes sprang was Puritan of the straightest sort. It was earnestly settling the fundamentals of individual and State development. Necessarily the ornaments and amenities of human life were given little attention. His ancestor left England and came to Newburyport, Mass., because he wanted an opportunity to worship God and conduct his daily affairs in accordance with ideas quite at variance with those prevailing in the land of his birth. This ancestor was a minister whose purpose was to aid in solving the problems involved in a government of the people directly responsible to God. Strange as it may seem to some, Dr. Noyes at one time had determined to become a minister, and had packed his trunk with the intention of entering a theological seminary, but a trivial incident diverted him to the study of medicine. From the date of landing on the bleak New England shore, his ancestors never swerved from their original purpose. He himself was born and reared on a Rhode Island farm, by parents sufficiently educated to conduct a private school, while they supported themselves by farm labor, taught their children those habits of industry, perseverance and thrift which characterized his career.

2. While ill-health prevented his securing a college training, he obtained all the education possible and never lost a chance to increase it during each year of his life. To the very latest moment he was adding to his store and to his ability to utilize it.

3. It would seem that he entered the profession of medicine because he loved it and all that pertained to it. It will be remembered that his medical studies covered a period of six years, though at that time but two were called for by any medical college. He was not content with study in one city, but studied in many, a fact which rendered him personally conversant with the most noted men of his student days. Further, during all his life he continued to pursue medical studies with zest, determined to keep himself in the front rank of a rapidly developing profession. Why he entered upon the study of ophthalmology is not clear; possibly the exposures incident to country practice in Maine during the winter months was too much for his physical powers, and the specialty of the eye then being a novelty, diverted him from general practice. Be this as it may, he spent much time and money in qualifying himself for his special work, and he never had any patience with those who entered medical work of any sort without the most perfect preparation.

4. Outside of medicine he was most interested in music. He thought that good music brought him nearest divine things. It stirred his whole being as it does but few. Hence he supported directly and indirectly all musical societies within his reach. His life was full of activity; in fact he was a model of industry. He never wavered in his devotion to the higher ideals of his chosen profession. He did the duties of each hour according to the light which he possessed. His affection for the Detroit Academy of Medicine never failed, his loyalty was unquestioned, and his faith in its future service to medicine unfaltering. As a man, as a patriot, as a citizen, and as a physician his life presents material for profitable study and emulation.

LONGEVITY OF PHYSICIANS.

Read before the Broome County (N. Y.) Medical Society, April 7, 1896.

BY JOHN M. FARRINGTON, M.D.

BINGHAMTON, N. Y.

All men think all men mortal, but themselves.—*Young*.

"It is a swift current—that stream of life, on which we ride. We fall asleep, and awaking, find ourselves almost home. Our companions, too, are constantly changing; at every moment new ones come aboard, and old ones leave us, and we have scarcely time to become familiar with their faces, or to make ourselves acquainted with their character or purposes, before they are summoned to the gangway the boat is lowered, and we wave them a friendly farewell. All along the sands of that silent shore, which we now so faintly see, our friends have left us; and we are awaiting the time when, cheerfully, manfully and hopefully, I trust, we shall receive our summons and depart 'alike to the inevitable grave.'"

—Extract from Dr. Frank H. Hamilton's Eulogium upon the life and character of T. Romeyn Beck, M.D., LL.D., February, 1856.

What I shall present upon the subject of the Longevity of Physicians will be more in the nature of a compilation of what I have been able to find published by my predecessors, rather than tables or deductions framed from my personal observation and experience. I shall therefore quote freely the substance, if not the exact language, of what I have found recorded. After a very diligent search for information on this, to me, interesting topic, I have been led to the conclusion, that there is quite a dearth of matter, thus far printed on this subject.

I am aware that heredity is the prime factor to be considered in forecasting the probable longevity of any member of the human family, and vocation is of secondary importance; nevertheless statistics prove that it has its influence beyond question in the life of the individual. Life insurance companies classify some vocations as extremely hazardous and decline to assume risks upon persons engaged in them. The scope of this paper is not designed to include, only for reference or comparison, any profession or vocation save that of the medical practitioner.

F. G. P. Neison, Esq., read before the Statistical Society of London, March 15, 1852, a paper "On the Rate of Mortality in the Medical Profession" accompanied with many full and elaborately constructed tables, the whole occupying thirty pages of the Quarterly Journal of the Statistical Society of London published in September, 1852. Mr. Neison's article considered the rate of mortality among two different classes of medical men: the one class being the officers of the Medical Department of the Royal Army and the other the members of the Royal Medical Chirurgical Society. The facts relating to the former were collected from the records of the Society for the benefit of the widows of the officers of the Medical Department of Her Majesty's Army established in the year 1816, and the facts, relating to the latter class were abstracted from the books of the Royal Medical Chirurgical Society established in the year 1805. Mr. Neison states that the utmost care was taken by him and the analysis was a laborious and troublesome one. The social condition of the members had an important influence on the rate of mortality and he found that the results of his analysis were not only exceedingly curious, but of great and practical importance. By social condition, Mr. Neison refers to married and single, his researches showing that the rate of mortality of the unmarried from 20 to 54 was 2.386 per cent, while the married for the same ages

was 1.872, and that from 55 to 84 the rate of the unmarried was 2.972 and the married 4.422; that is, that the mortality of single life is greater in the earlier ages and less at those ages more advanced. These tables however refer to those connected with the army. Mr. Neison's investigations relative to the members of the Royal Medical Chirurgical Society show the mortality of medical men differs but little from that of the general male population of England and Wales. Dr. Wm. A. Guy read a paper before the Statistical Society of London, Dec. 19, 1853, "On the Duration of Life among Medical Men." His essay embodied a table showing the average age at death in 260 members of the medical profession. He excludes all deaths by violence, accident or suicide, which I regret, as these fatalities are frequently concomitants or resultants of the practice of our profession. The arrangement of his tables are such that I have not been able to make any practical use of them. His conclusions are that the duration of life of members of the medical profession does not differ materially from that of the clergy; that the duration of life of physicians has somewhat increased during the last three centuries. He made a table of three classes of medical men, showing that the general practitioner exposed to so much fatigue, harassed by calls for his professional services, at all hours of the day and night, and often a prolonged attendance among those classes of the community with whom contagious diseases are most rife, have their lives shortened when compared with the other members of the same profession.

James Easton of London has published an account including the name, age, residence and year of decease of over 1,700 persons who survived 100 years and more, from the 1st to the 18th centuries. The official records of the Board of Health of New York contain a record of over thirty centenarians that died in that city during a period of three years and five months from Jan. 9, 1864, to May 15, 1867. It is stated that the oldest of the Greenwich and Chelsea pensioners all answered in the affirmative the two questions: Were you descended from persons of long life? Have you been in the habit of early rising?

Intemperance is one of the most pernicious agencies in shortening life, operating at all times and in all seasons, and is no respecter of persons or professions.

If an excuse or apology could justly be made for any one falling into the habit of intemperance, it could be made for the wearied and worn-out physician who whilst he should be an example of the proper mode of living is tempted to use alcohol in some form for the temporary stimulation he receives. But the fallacy, as well as the unfortunate results of such a course, is at the present time made more apparent, since the true position of alcohol as a medicinal agent has of late been so conclusively shown. That instead of being a stimulant and supporter of animal life it is a depressant, and is henceforth to be classed as an anesthetic and not a stimulant.

Mr. Neison, whose paper we have previously referred to, was an actuary of London and a high authority on statistics and has, from a series of careful observations, deduced some valuable statistics regarding this subject of intemperance, which prove that the average duration of life after the commencement of intemperate habits is among beer drinkers 21.7 years, of spirit drinkers, 16.7 years and among those who drink beer and spirits indiscriminately 16.1. He framed the annexed table of expectancy of life.

Age.	Temper- ate.	Intem- perate.	Loss of Life.	Per cent. of duration of life of Intemperate as com- pared with Temperate.
20	41.2 yrs.	15.5 yrs.	28.7 yrs.	35 per cent.
30	36.5 yrs.	13.8 yrs.	22.7 yrs.	38 "
40	28.8 yrs.	11.6 yrs.	17.2 yrs.	40 "
50	21.2 yrs.	10.9 yrs.	10.3 yrs.	51 "
60	14.3 yrs.	8.9 yrs.	5.4 yrs.	63 "

It was noticed that professional men addicted to drunkenness are shorter lived than drunkards in other pursuits. The influence of marriage upon longevity is a well established fact. Few unmarried centenarians will be found. The results of the observations of Dr. Guy were stated as follows: Mean average of married 66.7 years, of unmarried 62.0 years.

The superior longevity of the farmer over all other vocations is shown in all the tables of those who have made the subject of longevity a study. The following verse well portrays some of the causes that make the farmer's life more favorable to longevity.

"From toil, he wins his spirit light,
From busy day, the peaceful night;
Rich, from the very want of wealth
In heaven's best treasure, peace and health."

In the official registration report of Massachusetts for 1843 to 1866 the average age of the physicians who died during those years, 820 in number, was 55.84, a lower rate than Dr. Guy found in England, which he arranged in three classes, the lowest 67.04, the highest 72.95. The Massachusetts table gives that of lawyers 56.21, judges 66.38, clergymen 57.79, the judges being the highest in the list of sixteen different professional pursuits. Few physicians survive to extreme old age, but as a class they enjoy a comparatively long career, despite the risks of contagious diseases and the arduous nature of their duties.

Lieut. J. W. Maclay, in an essay on "The Relation of the Different Professions and Vocations to Longevity," published in 1873, divides longevity into normal and abnormal; the former denotes the average length of life and the latter advanced or extraordinary longevity. The average of life varies with the habits of the people as regards morality, industry and civilized culture. Ancestral history, as we stated at the beginning of this article, is of the first importance—if a good constitution has been inherited, long life is almost assured if ancestors were long-lived. There are many influences that affect the duration of life, *e. g.*, habits, vocation, residence, health and intelligence. Judges are long-lived not because their vocation is particularly favorable, but the inherited vigor that gives them judicial qualities enables them to bear the strain which short-lived persons would neither undertake nor sustain.

Statistic tables often fail to prove what they claim because they include in their averages such different kinds of persons, and thus mislead the student from noticing real causes and deductions.

The London *Lancet* of January, 1886, states as follows: "The weaker will sometimes prove himself the more tenacious of life by observing rational methods of living, of which the more robust is careless. Moderation has probably more to do with success in this respect than anything else. To eat sufficiently and drink stimulants sparingly, to alternate work with adequate rest and to meet worries heartily, will afford to every one the best chance of arriving at a ripe old age."

Dr. Wm. Ogle, Superintendent of the Statistical Department of the Registrar General's Office, read a paper on "The Mortality of the Medical Profession" before the Royal Medical Chirurgical Society in Lon-

don in January, 1886, from which I shall quote liberally. The census of 1881 showed that there were in England and Wales physicians, surgeons and general practitioners 15,091, and after the census was over, the causes of the death of all males aged 15 and upward in England and Wales during the three years 1880-82 were abstracted from the National Death Register, in combination with the occupation of the deceased persons.

The results of this process as regards the mortality of medical men was to show that their mean annual death rate in those three years was 7.40 per 1,000 between 20 and 25 years of age, 11.57 between 25 and 45, 28.03 between 45 and 65, and 102.85 per 1,000 at 65 and upward.

Dr. Ogle compares the mortality of medical men in those three years with that of men engaged in other pursuits, and gives a table showing the annual death rate in a number of different professions and trades. Each of the rates is calculated for 1,000 males aged upward of 20 years with the same age distribution as the medical profession. The death rate of medical men is shown to be far in excess of that of other professions. Thus, the death rate is 15.93 in the clerical profession, 20.23 in the legal profession and 19.90 in the scholastic profession, while in the medical profession it is 25.53. The rate in the medical profession is not only higher than in any of the other learned professions, but also compares unfavorably with the rates in most other trades and industries, and is indeed only exceeded by the rates in certain trades and occupations that are notoriously unhealthy.

Having established beyond doubt the fact of the marked excess in the mortality of the medical profession, Dr. Ogle proceeds to consider what are the causes to which this excess is attributed, or rather what are the diseases under which it occurs. This information has been derived from copies of the entries in the Death Register relating to the death of 3,865 medical men during the years 1873-82 forwarded to the General Medical Council in accordance with legislative enactment for the due correction of the Medical Register. Dr. Ogle's information based upon these facts is, as he asserts, unique in character. No similar information, unfortunately, exists for any other profession or industry. The number of deaths dealt with is fairly large. The deaths were spread over a period of ten years and they occurred in all parts of the country; they may therefore with full confidence be accepted as a fair sample of the causes of death of medical men. The 25,535 deaths estimated to occur annually among 1,000,000 medical men are therefore assumed to be caused by the various diseases in the proportion shown by the classification of the causes of the 3,865 deaths. The result of this distribution gives the annual death rate per 1,000,000 medical men from each cause of death dealt with.

A table is appended giving side by side with these death rates from the several causes among medical men, the rate for the same causes among all males in England and Wales, irrespective of occupation, and duly corrected for differences of age distribution. The result of this comparison is to show that, with very few exceptions, the mortality of medical men is higher from every disease or group of diseases than is the mortality of males generally. Under some of these headings the medical mortality is twice or thrice or even more times greater than the average. Passing over Dr. Ogle's comparison of the mortality from the

various diseases we notice the death rate from suicide, which is 363 per 1,000,000 among medical men against an average of 238 for all males, and it is further pointed out that the tendency to suicide is increasing in the medical profession, whereas no corresponding increase is shown in the figures for the general male population. In order to facilitate a comparison between the death rates from suicide in the three principal professions, legal, clerical and medical, the annual rates were specially calculated for the six years 1878-83; they are given as 128 for the clerical, 354 for the legal and 464 for the medical profession.

In the *Medical and Surgical Reporter* for February, 1881, I find it stated that Hecker's statistics confirm the fact that the duration of the life of medical men is notably less than the mean.

Dr. Escherich's tables show that in Bavaria of 100 men in each vocation, 53 Protestant pastors, 41 professors, 39 advocates or magistrates, 34 Catholic priests and only 26 physicians reach the age of 50.

Kayser finds in the region of Breslau the average age at which physicians die is 56 years, priests 58, professors 59, higher office-holders 64, apothecaries 64 and lawyers 64.

Hufeland, who wrote his work on "The Art of Prolonging Life," 100 years ago, in 1796, in writing of the longevity of physicians says: "Physicians, who so abundantly dispense to others the means of health and life, ought to claim here a distinguished place, but unfortunately this is not the case. It may be said of them in general, in serving others they are consumed, in healing others they are destroyed."

"At any rate," he says, "mortality is greater among practicing physicians than perhaps among men of any other profession. They have the least opportunity of observing those prudential rules and precautions for preserving health which they lay down to others; and there are few employments in which the powers both of the body and mind are exposed to so much consumption as in this. Head and feet must be always exercised in common. But the greatest mortality prevails during the first ten years of their practice. A physician who has fortunately withstood that period, attains to a certain strength of constitution, a kind of insensibility to fatigue and the causes of disease; by custom, noxious effluvia and the poison of infectious disorders become less prejudicial, and he acquires more indifference for the heart-melting scenes of woe and the numberless miseries, the consequences of vice and moral evil, which his business condemns him to be a daily spectator of; and thus a physician who has luckily passed his time of probation, may become an old man. A striking instance of this is afforded by our predecessor, Hippocrates, who lived to the age of 109. His whole life was employed in the study of nature, in traveling and in visiting the sick, but he passed more of his time in small villages and in the country than in great cities."

I have noticed a statistic table prepared by order of the legislature of Massachusetts at some time previous to 1858, which shows that the average age of physicians in that State was somewhat higher than that of the legal or clerical professions: Physicians 54.94, lawyers 54.13, clergymen 52.40, agriculturists leading the list at 63.93.

Dr. S. H. Freeman, president of the New York State Medical Society in the year 1858, in his annual address on "Human Longevity," was doubtless encouraged from a study of this Massachusetts record

to give expression to the cheering assertion "that the vocation of the physician though perhaps exposed to the severest vicissitudes and trials, in wearisome days and anxious nights, is not unfavorable to longevity; for medical men, from the general activity of their profession, their knowledge of the causes which promote health, and the wholesome exercise of the mind and body, are often enabled to enjoy long lives of active beneficence in dispensing those grateful charities, that cheer and soothe and bless."

According to Dr. Jarvis' tables, the average duration of the lives of physicians is 56 years. Consequently a physician who begins practice at the age of 24, his active profession life will be 32 years.

The Massachusetts Medical Society published a list of their members who died in 1870 and 1871, thirty-seven in number. The ages of thirty-two are given, averaging 60½ years, the extremes being 28 and 84. This, as well as the previous record from Massachusetts, gives a longer tenure of life than common opinion allots to our profession. My old friend and beloved teacher, Prof. E. R. Peaslee, who died at the age of 64, in an address in March, 1851, before the Medical School of Maine, at Brunswick, said: "The constant exertion of body and mind in medical practice, actually renders the average of life several years less in medical than in the other two professions." He quotes statistics for 1846 collated by the State of Massachusetts, giving the average of deceased clergymen 64 years, of lawyers 59 and of physicians only 47 years.

Dr. Casper, of Berlin, in 1834 deduced from statistics the following longevity of different callings: To 42 theologians that attained the age of 70 and upward there were agriculturists 40, commercial men 35, advocates 29, artists 28, teachers and professors 27, and physicians only 24.

M. Quetelet in "A Treatise on Man," Edinburgh, 1842, remarks that it would seem to follow from the above table that mental labor is more injurious to man than bodily; but that the most injurious state of all is that where fatigue of body is joined to that of the mind.

The mortuary registration for the year 1839 in England gave the average ages of deaths of persons in the three professions as follows: Clergymen 59, lawyers 50, physicians 45. T. W. Higginson is responsible for the statement that "Prof. Pierce has proved by statistics that the best scholars in our colleges survive the rest; virtue like intellect doubtless tends to longevity."

Dr. G. W. H. Kemper, of Muncie, Ind., in the *Indiana Medical Journal* of February, 1895, in an article on the "Longevity of Indiana Physicians," states that he found in the "Transactions of the Indiana State Medical Society," from 1880 to 1894 inclusive, 213 deaths of physicians recorded. These were representative men of the medical profession in that State, and their ages, in the opinion of Dr. Kemper, gave a fair estimate of the longevity of our profession. Of these 6 died in the twenties, 29 in the thirties, 49 in the fifties, 62 in the sixties, 33 in the seventies and 9 in the eighties. The ages of the octogenarians were as follows: Four reached 80, one 81, one 82, one 83 and two reached the highest, 88. The 213 persons lived 12,088 years, which gives an average of 56 years and 9 months to each person. Three of them met violent deaths at comparatively early ages, two having been run down by railway

trains and one assassinated; but for these accidents Dr. Kemper states the report would appear better.

Dr. Salzmann, of Essling, Germany has made a study of all the available facts regarding the longevity of physicians to be found in the records of his country, going back as far as to the sixteenth century. In that period the life of the medical man was 36.5, in the seventeenth 45.8, in the eighteenth 49.8, and in the current century 56.7. The comment is made that the increased life rate is the result of the growth of preventive medicine, and especially those measures that have reduced the extension of smallpox and contagious fevers.

At a meeting of the Illinois State Board of Health (the date of which I have been unable to obtain), Dr. John H. Rauch presented a report upon the mortality rate and causes of death among physicians. The paper contains many facts of interest. Dr. Rauch's observations are based upon data accumulated in the ten years preceding his report, regarding Illinois physicians. He finds that the average duration of life among them is lower than is usually supposed to be the case among physicians, viz., 52 years, and that only 11 out of every 100 reach the scriptural limit of three score and ten. During those ten years under observation there had been about 6,000 physicians living annually in the State, among whom there were annually about 80 deaths, giving an annual death rate of 13.3 per 1,000. We will not quote the table published with his report, which shows that the death rate among physicians in the earlier part of their practice is lower than among males generally, or even in the general population. After the age of 40, however, the death rate is proportionately greater, and after the age of 60 it is higher than in the general population. The doctor after he gets to be 40, therefore, should be more than ordinarily careful, for his chances of life are less than those of his neighbor. With regard to the causes of death Dr. Rauch gives tabulated statistics, and adds: "Of the grouped causes of death, consumption, diseases of the respiratory organs (including 91 from pneumonia) and Bright's disease caused 268 deaths, or more than one-fourth of the total. If to these be added a share of the deaths from diseases of the heart, the sequelæ of rheumatism, a fair estimate may be made of the effects of exposure to the vicissitudes of weather upon the wear and tear of medical life. As a result of mental strain and anxiety, of insufficient, irregular and interrupted sleep and similar causes in the total of deaths from diseases of the brain and nervous system, embracing forty-three from various forms of paralysis. In the group of zymotic diseases (enteric fever given separately) there were five deaths from diphtheria, one each from smallpox and yellow fever and eight from traumatic infection (septicemia, etc.), all contracted from attendance upon patients.

Less creditable to the *morale* of the profession are the eighteen deaths from overdoses of opiates and narcotics, the seven admitted suicides and the deaths from alcoholism, direct and indirect, twelve of the former and at least eight of the latter."

Dr. J. L. Kortright, in the *Brooklyn Medical Journal* for June, 1895, has an article on the causes of death of medical men in Brooklyn and New York for the years 1884 to 1892 inclusive. The mortuary statistics includes 450 physicians. The average of age at death was 54.6. He does not publish the entire table of diseases but states that a large proportion of

them may be classed as accidental and in no way dependent upon the pursuit of the practice of medicine. The startling announcement is made that the mortality from suicide among physicians is four times that of other adult males. In most cases death was caused by poison. Frequently the suicide was unintentional and resulted from an accidental overdose on the part of some victim of a drug habit. Pneumonia furnishes a large death rate, which would be expected when we consider the exposure to inclement weather and night air incident to the practice of our profession. Bright's disease, apoplexy and various forms of heart disease are grouped together as all having common pathologic conditions, viz., arterial sclerosis and degeneration of the muscular fibers. The mortality from these causes was 35 per cent., whereas the usual death rate from these causes among all male adults is only 25 per cent. Arterial sclerosis was a cause of over a third of all the mortality. In concluding his article Dr. Kortright gives the following sage advice and warning: "The lesson, then, that we should learn from our deceased colleagues is not to work too long. When you find your arterial tension increasing, your temporal artery becoming tortuous, your radial growing hard, especially if you have a little palpitation and pass an increased amount of limpid urine, whatever your years, know that old age is upon you. Henceforth shape your life like one that is old. Curb your ambition. Be content with a small practice. Reduce your expenses. Give up your night work. Decline confinements. Take a long vacation in summer. Retire early. Eat abstemiously. Drink not at all. Sell your horse. Take a great deal of moderate exercise in the open air. Watch the functions of the skin. Guard against a chill. Cultivate an even disposition. Study to be quiet."

I have nothing but commendation for what the doctor evidently means in these laconic sentences and yet it seems to me that at least two of them need a little qualification or amplification. "Sell your horse" means, I presume, so that you will get more exercise in walking, but some patients would be too far distant to visit on foot, and after sufficient exercise on foot driving is both healthful and pleasant. The other sentence, "Drink not at all," leads me to think that Dr. K. is a Kentuckian, as I recall reading the experience of a traveler in Kentucky who on a hot day, weary and parched with thirst, stopped at a house by the roadside and asked the resident if he could give him a drink. The reply was, "I am very sorry, my dear sir, but I have not anything to offer you." "Why," said the traveler, "is not that a well?" "Oh, yes; yes; you can have all the water you want, but I thought you *wanted a drink*."

Dr. E. J. Marsh, in an address on longevity delivered before the Medical Society of New Jersey, of which he was President, in June, 1892, states that the medical profession does not stand high in the list and the mortality is great in comparison with that of other professions. The hard physical work, the exposure to vicissitudes of weather and the contagion of diseases, the disturbance of regular hours of sleep and food, the mental strain and anxiety from responsibility for life or death are all prolific causes of sickness or of premature decay. The dangers and burdens fall chiefly upon the young men and those in the prime of manhood and when this stage of life is safely passed the mortality of physicians approximates the average for the other professions.

Of 89 presidents of the New Jersey State Medical Society whose deaths are recorded in the "Transactions," 24 died under 60 years of age, 34 between 60 and 70, 20 between 70 and 80, 10 between 80 and 90, and 1 at 93. At the date of Dr. Marsh's address Dr. Enoch Fithian, of Greenwich, N. J., had passed his centennial birthday. Dr. Holyoke, of Salem, Mass., practiced his profession for seventy-five years, and even after his hundredth birthday was consulted and gave medical advice. A statement was published in April, 1895, that Dr. de Bossy, the oldest of French physicians, was born in 1793, that he had never been ill and was still in active practice in Havre. He rises at 7, summer and winter, and as soon as dressed starts on his rounds, usually on foot. He attributes his longevity to moderation in all things. His father lived to be 108, and in that fact more than to his own conduct do I attribute this long life of the son.

Dr. William Salmon now living in Glamorgan, England, entered his 107th year March 16, 1896. He is still in excellent health. His father was also a physician. He derives deep pleasure from the faith that he is the oldest justice of the peace, the oldest physician, and the oldest freemason in the world, and Gladstone, who is young enough to be his son, sends him a birthday telegram every year, with his sincere wishes for here and hereafter.

The most remarkable instance of longevity that ever came under my own observation was that of a hale farmer, Samuel Vann, living in the town of Ulysses, Tompkins County, N. Y. He was born in New Brunswick, N. J. He was never ill, so far as I have been able to learn, until a few days before his death. He walked about the country, going frequently several miles in a day, until just preceding his death, which was some acute disease, I should think peritonitis, from what I have learned about it. He retained full possession of all his faculties, transacted all his business personally and gave no indications of such advanced age. Hon. Irving G. Vann, recently appointed by Governor Morton as one of the Judges of the Court of Appeals, is a grandson of Samuel Vann, who died March 19, 1877 after he had entered upon his 107th year. I saw a man 108 years old, but he was confined to his bed and as helpless as an infant. He was the father of Rev. Marshall, a Baptist clergyman living at that time in Covert, N. Y.

Shepard Homans, the great life insurance actuary, in 1891 published some matters of great interest in reference to longevity in general. He says man grows 20 years and his natural limit of life is 100 years. It has been found that the natural limit of life in all animals is about five times the period of their growth or complete development. Thus the camel grows 8 years and his natural life is 40; the horse grows 5 years and lives 25; the ox grows 4 years and lives 20; the dog grows 2 years and lives 10; and the hare grows 1 year and lives 5.

Buffon states: "That the man who does not die of accident or disease lives everywhere to 90 or 100 years of age." Hufeland says: "Nearly all those deaths which take place before 100 years are brought on artificially, that is to say, by disease or accident." Dr. Farr in the Sixteenth Annual Report of the Registrar General of England says: "The natural term of human life appears to be 100 years." Finally the prophet Isaiah says, lxx, 20: "There shall be no more thence an infant of days, nor an old man that hath not filled his days; for the child shall die an 100 years old." The

extreme limit of life, Homans states, appears to be about twice the natural term or limit. Thus instances have occurred of man living to 200 years, or very nearly; and Buffon relates with much minuteness the history of a horse that lived 50 years. "How are we to account for the ages recorded in Genesis," says Homans, "of Adam, his sons and Methuselah?" "We can not disregard the teachings of science, nor need we doubt the statement in Holy Writ. Each has Divine authority. By what theory can we reconcile the two. Simply that the year or unit of time among the early patriarchs differed from that adopted since the Deluge, which has been twelve calendar months." Hensler, a high authority, shows the strong probability that the years till the time of Abraham consisted of three months only; that it was afterward extended to eight; and that it was not until the time of Joseph that it was made to consist of twelve. These assertions Hufeland (1796) states are in a certain degree confirmed by some of the Eastern nations, who still reckon only three months to the year, and besides it would be altogether inexplicable why the life of man should have shortened one-half immediately after the flood. It would be equally inexplicable why the patriarchs did not marry till their sixtieth, seventieth and even one hundredth year; but this difficulty vanishes when we reckon these ages according to the before mentioned standard, which will give the twentieth or thirtieth year, and consequently the same periods at which people marry at present. The whole therefore, remarks Hufeland, according to this explanation, assumes a different appearance, and with the period of Abraham, we find mention of a duration of life which can still be attained and which no longer appears extraordinary, especially when we consider the temperate manner in which the patriarchs lived, and therefore we reach the comforting assurance that man can still attain to the same age as ever. I have made diligent inquiry to verify the above statement, but have been unable to find any corroborative evidence that any Eastern nations now or ever have had years less than twelve months, which was the Jewish year not only, but also the Egyptian. I am surprised that this important statement from so high an authority should have passed unchallenged so many years, as Erasmus Wilson, F. R. S., published the translation of Hufeland's *Art of Prolonging Life*, in 1853, and as late as 1891 Shepard Homans refers to it as a very satisfactory explanation of what would otherwise seem difficult of comprehension.

In recently looking over the transactions of our (N. Y.) State Medical Society, it seems as though I was walking through a graveyard where were buried a host of my medical friends or acquaintances, and that on every side of me were the headstones or monuments recording their names, ages and brief notices of their earthly labors and the professional honors which they had won during their active professional lives. Each and every volume of the *Transactions* contained obituaries of former members read by surviving professional brethren who in turn, soon after, or at least many of them, lay down the burden of life and were represented in later volumes by some medical friend presenting their obituary memoirs. I was much surprised on reading these memoirs to notice that most of these physicians died at an earlier age than I had supposed, though at the time of their death I knew their ages, yet somehow in the lapse of time that had occurred I had retained an impression that

they were older men than the published records now show they were. Some of them were privileged to have the poet's wish:

"To glide my life away! and so, at last,
My share of duties decently performed,
May some disease, not tardy to perform
Its destined office, yet with gentle stroke,
Dismiss me weary to a safe retreat
Beneath the turf that I have often trod."

Others were summoned by long and painful maladies, yet were

"Sustained and soothed
By an unfaltering trust."

"The air is full of farewells to the dying and mournings for the dead, but our ears are so dulled by the iterated sounds that their dread import rarely reaches our hearts; unless on occasions when we are appalled by the intrusion of death stalking into our own households, or invading the circles that embrace those with whom we are accustomed to associate, and whom we hold in regard for qualities that have endeared them to our hearts and capacities that have commanded our admiration."

Whilst passing in review the life and character of many professional friends and acquaintances of former years, and as I have scanned the death record of the past for the facts here recorded, the solemn words of Daniel Webster have come forcibly to mind, for he left on record his deliberate convictions regarding professional fame in these words:

"Professional fame fades away and dies with all things earthly. Nothing of character is really permanent but virtue and personal worth; these remain. Whatever of excellence is wrought in the soul belongs to both worlds. Real goodness doth not attach itself merely to this life. It points to another world. Political or professional reputation can not last forever; but a conscience void of offence toward God and man is an inheritance for all eternity."

In bringing to a close this compilation of what I have been enabled to secure upon this interesting subject, I desire to state that I have no doubt that there is much in print that I have failed to find, not having had an opportunity to visit any of the large libraries of our cities while preparing this article. Nevertheless, I trust that some one else will, by reading what I have collected, be prompted to supplement my article with fuller details and statistics from other sources. It would not be a very tedious task for the secretary of every medical society to tabulate from the mortuary records of its members a table and statistics of real value and interest. And every State and city of our country that has a system of recording the vital statistics could furnish much material for a paper on the longevity of physicians. Our State of New York has these records since 1880, but in a recent correspondence with Dr. B. F. Smeltzer, the Secretary of the State Board of Health, he states as follows: "It is regretted that the information you desire has never been tabulated; the records, however, are at your disposal at any time you wish to consult them or send a representative to this office for that purpose, when we would be pleased to aid you in securing the desired information."

To the older members of our profession I desire to speak words of cheer, for old age has opportunities for usefulness equal to any period of life. The veterans in medical practice have solved many problems that the younger practitioners are still wrestling with.

Experience is the most efficient teacher and one whose lessons are least likely to be forgotten. How many visionary theories have been traversed and found baseless; how many lessons taught us by honored professors have proved of little value; but the lessons we have learned from practical experience and careful observation, repeatedly tested, have proven to be an anchor to our souls when we have been tossed upon the waves of tempestuous controversy and adverse criticism. We find solace often in that couplet:

"One self-approving hour whole years outweigh,
Of stupid starers and of loud huzzas."

If confident that we are correct in our diagnosis and procedure, we may calmly rest while the hurricane of discordant criticism may roar about us. Longfellow thus encourages old men, and these words should give inspiration to every member of our loved profession on whom the infirmities of age are resting.

"But why, you ask me, should this tale be told
To men grown old, or who are growing old?
It is too late. Ah! nothing is too late
'Til the tired heart shall cease to palpitate.
Cato learned Greek at eighty; Sophocles
Wrote his grand *Oedipus*, and *Simonides*
Bore off the prize of verse from his compeers
When each had numbered more than fourscore years:
And *Theophrastus*, at fourscore and ten,
Had but begun his *Characters of Men*.
Chaucer at *Woodstock* with the *nightingale*,
At sixty wrote the *Canterbury Tale*:
Goethe at *Weimar*, toiling to the last,
Completed *Faust*, when eighty years were past.
These are, indeed, exceptions, but they show
How far the Gulf stream of our youth may flow
Into the Arctic regions of our lives,
Where little else than life itself survives."

A PRACTICAL OPHTHALMOSCOPE.

BY EDWARD JACKSON, A.M., M.D.

PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC,
SPECIAL LECTURER ON PHYSIOLOGIC OPTICS IN THE UNIVERSITY
OF COLORADO.

The Sight-hole.—The principal use of the ophthalmoscope is to enable us to study the interior of the eye. The use of its lenses for the measurement of refraction is of much less importance. In most of the forms of the instrument employed in this country its principal use has been somewhat sacrificed to assist its less important function. To measure refraction with the ophthalmoscope it is necessary by using a large sight-hole to exaggerate the blurring caused by imperfect focusing. For the other uses of the ophthalmoscope this blurring should be reduced as much as possible. It can not be entirely corrected by lenses, because in all eyes, with the pupil dilated as in a dark room, there is irregular astigmatism which no lens can correct. Such blurring is reduced directly in proportion to the reduction in the size of the sight-hole: hence, the most distinct view of the details of the eye-ground is only to be obtained through a small sight-hole.

Again, one of the chief obstacles to obtaining a view of the fundus is the reflection of light from the surface of the cornea. The reflection gives rise to a minute image of the source of light apparently situated a few millimeters behind the cornea; and, therefore, so close to the surgeon's eye that the light from it falls on his retina in a circle of diffusion. The size of this circle is directly proportioned to the size of the sight-hole in the ophthalmoscopic mirror, through which the light is admitted. If this circle be larger

than the image of the patient's pupil, the pupil is seen as through a luminous cloud. But if the circle of diffusion be smaller than the image of the pupil, the view through the part of the pupil not covered by the luminous cloud will be clear. The reflection from the patient's cornea is the main obstacle to the examination of the eye without the use of a mydriatic, and particularly to the examination of the region of the macula. For the great mass of ophthalmoscopic examinations it is therefore the most serious obstacle. The sight-hole of three or four millimeters in diameter, used in most ophthalmoscopes, is too large. One of two millimeters in diameter is distinctly to be preferred for the great bulk of ophthalmoscopic work.

The Lens Series.—Another point in which convenience has been sacrificed for the supposed ability to more accurately measure refraction with the ophthalmoscope is in the number of lenses employed. The excesses in this direction are sometimes almost ludicrous, and become entirely absurd when put forward as the especial virtues of an instrument. Others who have made considerable practical use of the ophthalmoscope have noticed this and referred to it; for instance, Knapp (*Archives of Ophthalmology*, 1895, p. 552) in commenting upon the double-disc ophthalmoscopes of Loring and Knauer, speaks of them as having "a superfluous wealth of glasses." "These instruments are less inconvenient than other double-disc ophthalmoscopes, but with regard to easy handling are still inferior to the single-disc instruments, and these can be made to carry a number of glasses sufficient for all purposes."

These instruments have lens series in which, for the weaker lenses, the interval is one-half diopter. I have never known an ophthalmoscopist who, I thought, could measure refraction with the ophthalmoscope to the accuracy of one-half diopter in a large proportion of his cases. I am sure that for the ophthalmoscopist who is not daily measuring refraction with the ophthalmoscope under most favorable conditions, such an interval between the lenses is a delusion and a snare. He will do more accurate work with a greater interval, say of one diopter, which will cause a sufficient blurring when the correcting glass is departed from, to be certainly recognizable. Loring (*Text-book of Ophthalmoscopy*, Part 1, p. 111) says: "I feel convinced that it is very difficult, sometimes impossible, with young people to tell the lighter degrees of H (less than .75 D.) with the ophthalmoscope;" and on page 118, that degrees of astigmatism "as low as 0.75 D. can be detected by this test, provided the accommodation in both the observed and the observing eye is perfectly relaxed." Loring refers to the measurements of refraction with his own ophthalmoscope, having a sight-hole almost four millimeters in diameter. With the sight-hole reduced to improve the instrument for its primary uses, the value of the half-diopter interval between the lens is correspondingly reduced. There is, therefore, no reason for an interval of less than one diopter between the lenses of the instrument that is to be most useful for the general practice of ophthalmoscopy.

In the measurement of refraction with the ophthalmoscope it is very important, indeed it is absolutely essential, for accuracy, that two lenses which are to have their effects compared as to blurring of the image, should be so arranged that the one can be substituted for the other without taking the instrument

from the eye. Slight changes in the distinctness of the image are worthless when the change from one to the other can not be made instantly. On this account no lens series can be considered satisfactory which is not all available without removal of the instrument from the eye.

Focus of the Mirror.—Where a single mirror is furnished with the ophthalmoscope it has been customary to give it a focal distance of eight or ten inches. This would give to parallel rays a convergence of four or five diopters. The rays, however, that fall on the ophthalmoscope mirror are usually divergent from a point not more than twenty or thirty inches away, and such rays leave the mirror only two or three diopters convergent, so that they are perfectly focused on the retina of an eye two or three diopters hyperopic; and are almost perfectly focused on the retina where the

hyperopia is lower than this. When this is the case there is formed on the fundus of the eye examined a little inverted image of the source of light, which makes a most unsatisfactory area of illumination. To secure a more uniform, diffuse illumination, for a great majority of eyes which present low or moderate degrees of hyperopia, the rays entering the eye must be rendered more convergent, so that they will focus in front of the retina and form upon the fundus an area of comparatively uniform diffusion. The focal distance of the ophthalmoscopic mirror, to accomplish this, should be not more than three or four inches. If, for any reason it is desired to throw into the eye, as in myopia, rays that are less convergent or parallel, this may be effected with such a short-focus mirror by bringing the source of light close to the mirror.

A Modified Form of Ophthalmoscope.—In 1885 I

showed before the American Ophthalmological Society a new form of ophthalmoscope, and in the following year suggested additional lens series for it (*Transactions American Ophthalmological Society*, Vol. iv, pp. 111-361) which, with the arrangement of lenses in two slides moving vertically behind the mirror, allowed of the combination of lenses, and of a sufficient lens series completely available, without removal of the instrument from the eye. This form of instrument has since been widely used, and is still, in most respects, entirely satisfactory. But the lens series, the focal distance of the mirror and the size of its sight-hole then adopted, conformed closely to those of other standard ophthalmoscopes, and experience has shown more and more clearly that these were capable of considerable improvement. I, therefore, recently had made by Queen & Co., of Philadelphia, the instrument shown in the accompanying cut, upon the mechanical plan of the earlier instrument, with a mirror of four inches focal distance, having a sight-hole two millimeters in diameter, and with the following lens series:

Convex, 1, 2, 4, 6 and 15 diopters.

Concave, 1, 4, 7, 10 and 30 diopters.

These, by combinations, furnish the following lens series, every number of which is available without the instrument being taken from the eye:

Convex, 1, 2, 3, 4, 5, 6, 8, 11 and 15 diopters.

Concave, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15 and 30 diopters.

As to the advantages of this lens series, we have already discussed the worthlessness of a shorter interval than 1 D. for the weaker lenses. The convex series furnishes each diopter to six, then skips to eight, and so on. It should be remembered that hyperopia of over six diopters is rare. Among 4,000 eyes I found only eighteen having more than this amount of hyperopia (*Trans. Am. Ophthalmol. Soc.*, 1889, p. 438). Then, too, by withdrawing the six diopter lens one and five-eighths inches from the eye it measures eight diopters of hyperopia, and at intermediate points measures all intermediate amounts. Really, for the measurement of refraction, no stronger convex than ten diopters is required in the ophthalmoscope, but it is convenient to have a stronger lens for the ophthalmoscopic examination of opacities in the cornea, crystalline lens and vitreous.

It will be noticed that the series of concave lenses gives each diopter up to ten. In the 4,000 eyes above referred to, 24 presented myopia of over ten diopters. But here again the variation of the distance of the lens from the eye enables a few strong concave lenses to measure every degree of myopia; thus the thirty diopter concave held one and one-fourth inches from the cornea measures but fifteen diopters of myopia, and at shorter distances from the eye measures intermediate amounts. If one wishes to be even approximately accurate in the estimation of high degrees of hyperopia and myopia with the ophthalmoscope, he must always measure the distance of the ophthalmoscope lens from the patient's eye, and allow for it; and this process is simplified by having a few well-chosen strong lenses.

It is doubtful if a more extended lens series than this was ever of practical advantage to the mass of ophthalmoscopists, and the accurate measurement of refraction with the ophthalmoscope by the direct method is of far less importance since the introduction of skiascopy. Every lens in a series that is not

needed is a source of possible inaccuracy and a nuisance. It is just as important to have no useless lenses that must be run over in finding the right one, as it is to have at command all that are really needed.

TUBERCULAR PERITONITIS.

BY BYRON ROBINSON, B.S., M.D.

PROFESSOR OF GYNECOLOGY IN POST-GRADUATE SCHOOL,
CHICAGO.

At this time experiments are rife in every direction. Even the laity demand cause and effect and ask the question: "What is the practical effect of trial?" Peritoneal tuberculosis has interested me for years, and of late the apparent cure by abdominal incision and drainage.

After considerable observation for the past eight years in tubercular peritonitis, I must say that the so-called surgical therapeutics lack an essential base of explanation. I have posted about twenty cases of tubercular peritonitis, operated on some eight to ten patients and made some careful observations on three cases in Professor Senn's clinic, having therefore over thirty cases of quite careful observation.

To be short, in regard to the cases of abdominal section to relieve peritoneal tuberculosis, I will say that all recovered, except the sixth case, after the operation, and became so well that they left the hospital and passed into the unknown field outside the hospital, from which few report, and I have lost all trace of them. They regained a very large part of their health before leaving the hospital. The sixth case died, I think between two and three weeks after the operation, not from the surgical procedure, but from extension of the peritonitis due to tuberculosis. I unhesitatingly say that the tubercular peritonitis in the stages at which I operated appeared to be benefited in all, and at least temporarily improved all but the one case too far advanced.

The present state of the subject of peritoneal tuberculosis is entirely unsettled. Opinions have a wide swing, an extreme swing among surgeons, gynecologists and internal medical men. But so do all subjects until natural experiments force a more rigid standard of decision. It requires many experiments to learn a small number of natural laws. The more wild and varied opinions on any subject, the rarer the opportunities one has for testing his experiments. Ten years ago we relatively knew nothing of the subject in regard to its therapeutics. If I remember rightly it was an old veteran, the methodic and abdominal surgeon, Spencer Wells, who opened the abdomen of a patient possessing a tubercular peritonitis in 1865. In 1885, it seems to me, she was reported alive, twenty years after. This, of course, was a long forgotten circumstance and experiment. But people easily forget matters. It requires a tenacious grip to remember the long-continued effects of good and bad result.

The condition of some cases of peritoneal tuberculosis precludes any possibility of recovery by any known therapeutic agent. There are two forms which we meet in tubercular peritonitis, viz. (a) the dry form, and (b) the moist variety. The dry form appears quite red, congested, and presents large, thick, swollen diseased parts. The ligamentum peritonei is dense, but friable. In cases in which Dr. Lucy Waite and I performed laparotomy the disease had progressed very extensively, showing enormous pathologic products, and yet a year afterward present fair appearances.

The broad ligament with the tube may be thick and twelve to fifteen times their original size. The peritoneum was studded with large and small tubercles. Three weeks' drainage improved the patient very much. Some of the patients presented the most formidable conditions of callosal nodules, and yet were wonderfully improved. It would seem the dry form is amenable to treatment. The second variety is the hydrops peritonei tuberculosis, the moist variety. Ascites slowly arises and the abdominal cavity gradually swells. It is quite likely that it is the chief one of destruction.

In opening the abdomen one may not be able to see the innumerable small, fine miliary tubercles, but one can feel them. When large enough to see they look like small blisters studding over the omentum majus, mesentery and visceral peritoneum. After a certain time or size of the tubercle, degeneration occurs at its center and its caseous degeneration may result in an ulcer; when more advanced bowel perforation results.

On opening the abdominal cavity the first organ, in general, is the omentum majus, for it seems that the business of the omentum majus is to meet emergencies in the abdomen. It seems to be prepossessed of attempting to defend the abdominal cavity by meeting and monopolizing the invading disease. By tracing the omentum majus one is very liable to discover the primary tuberculosis, which in woman is so often from the Fallopian tubes. The omentum is like a man-of-war, it guards the ports against hostile entrance, it is the great peritoneal protector against infectious invasion and the surgeon's good friend to cover up the mischief his hands have wrought. It is asserted by Senn that we meet with peritoneal tuberculosis in the female the most frequently. This is not in accord with the peritoneal tuberculosis I found in 350 personal autopsies, for we found it more frequent in males. From the appearance of the subject it seems that they have other organs than the peritoneum affected.

The present trend in tubercular peritonitis is to perform an abdominal section; yet the very reason against such procedure is that we still know nothing about the real method of cure. And in truth, do we really know whether the section actually cured, or would the patient have done as well without the section? Pibram undertook the tedious labor of finding out how many died of tubercular peritonitis in the pathologic institute of the University of Prague, according to Vierordt, and he found that 165 out of 3,500 died of tubercular peritonitis, *i. e.*, about 5 per cent. A mortality of 5 per cent. from tubercular peritonitis is about what agrees with some other estimates. It seems that in one series of one hundred autopsies which the pathologists and internes of Cook County Hospital were kind enough to allow me to carefully examine during the autopsy, some six died of tubercular peritonitis and several others possessed peritonitis which suggested the same pathologic process, but died from other causes or from tubercles in some other viscus. Differences of opinion arise among physicians from differences of circumstance in life. The surgeon sees one kind of tubercular peritonitis, especially two forms, *e. g.*, large ascitic abdomen, not only enlarged by fluid, but by boggy masses arising from exudates or inflammation in the omentum or mesentery, both stiffening the mesenterium and omentum so that through emaciated abdominal walls

the surgeon distinctly maps out the tumor. Now, just in these cases the surgeon operates, and it may be that this surgical cure which we do not understand is in just such cases. The gynecologist, to a certain extent, may be classed with the surgeon, but he is generally better able to understand the conditions from his more extensive experience in the abdominal cavity (in this country at least, where gynecology and surgery are becoming so widely separated).

Some of the cases reported in this paper appeared simply hopeless from tubercular invasion of the peritoneum. The most advanced cases and the most profoundly affected were those of the dry variety. They were all women but one; two of them, operated on by Dr. Lucy Waite and myself, showed the parts perhaps fifteen times thicker than normal. In one of them it is a year after the operation and in another some ten months; and reports are good. The tubes, broad ligaments and lower omental border presented immense shapeless masses with scarcely any ascites. One case is about three years old, in which Dr. Bertha Van Hoosen assisted. A point of some interest is that the omentum is frequently found at the primary seat of the tubercular peritonitis. It is not easy to explain the predilection of the omentum for the primary seat of peritoneal inflammation. It is absolutely astounding how a human being can live so long with such vast and serious lesions as tubercular peritonitis produces. The peritoneum may become an inch thick. Small and large ulcers beyond count with large tubercles stud the ligamentum peritonei, visceral and parietal peritoneum almost beyond conception. The mesenteric gland may become the size of a hen's egg, and one is amazed at the innumerable mesenteric glands which suddenly come into view in tubercular peritonitis, which normally attract little or no attention from size or number. Tubercular peritonitis is one of the best of nature's experiments to demonstrate the lymph node and the effort of the lymph nodes or glands to check the bacillary invasion. I have noted several large bowel perforations screened and protected by vast deposits of adhesions. It may be noted that these patients generally have other tubercular lesions, as pleuritis, pulmonitis and joint affections. They generally have a tubercular habit or shape and show to the clinician that they are subjects in which to suspect tuberculosis. It is well understood that lupus is a skin, or surface tuberculosis, and that it is quite amenable to surgical treatment, *i. e.*, a thorough curettement or application of the Paquelin cautery will relieve them for eight to twelve months. It may be that the surface serous tuberculosis which is so amenable to treatment is of a similar nature. It is not clear what drainage accomplishes. Does it relieve intra-abdominal pressure? Does it initiate changes in the stomata vera, the fluid regulators of the peritoneum? It may induce rapid multiplication of leucocytes, which swarm to the peritoneal surface and destroy the bacilli. I have injected the rabbit's peritoneum with Berlin blue suspended in fluid, and found that in ten hours the leucocytes have swarmed out on the surface and seized particles of Berlin blue and hastened back through the stomata into the lymphatics of the diaphragm. The leucocytes surround the particles of blue or coloring matter and it then becomes a foreign body no more. It is encapsulated in protoplasm. Of course these leucocytes may be out into the peritoneal cavity for something to eat, but they have not the discriminating powers to

decide what is food and what is not, so they seize any foreign body invading the peritoneum, whether it be in soluble coloring matter or vegetable microbes. The microbes the leucocytes may digest, englobe or destroy. Some leucocytes carry back into the diaphragmatic subserous lymph channels many particles equal to the 100 tubercle bacilli. Scores of leucocytes may be found loaded with particles of coloring matter lying in both straight, superficial and deep channels of the diaphragm.

It seems to me that the cure of tubercular peritonitis, if it be recognized as such, by incision and drainage (and iodoform) must rest back on the power of the leucocytes to fight the battle against invading microbes. In some cases there will be a deposit on the peritoneum sufficient to make it an inch thick. In other cases the adhesions are so dense and so extensive that several bowel perforations will be entirely protected by the adhesions. Surely no incision or drainage will benefit such; they are beyond the art of surgery.

The man who practices internal medicine sees the patient in another and very different condition. He is visited by patients with peritoneal tuberculosis of lighter grade. They are simply slightly ill, constipated, weak; sweat, have no appetite; occasionally sharp diarrhea attacks them. Examination of the abdomen reveals very little, no palpable tumors, omental and mesenteric thickening. In short, they are in a transitional stage between being compelled to stop labor and going to a surgeon. The different stages in which internal medical men and the surgeon find the cases of tubercular peritonitis in cities, cause different opinions as to the course of the disease and the results of therapeutics on the disease. My view is that the claim that abdominal section is a cure-all for tubercular peritonitis is not founded on facts, but founded on imagination. We do not understand how section cures it, nor has any one offered a satisfactory explanation. They claim that air passing into the peritoneal cavity produces the cure. Could they settle the fact by injecting air into the cases where microscopic examination had proved the presence of the tubercular bacillus? But we think we know to-day that tuberculosis is a curable disease, *i. e.*, it may be arrested and not kill a patient. Again, I think that many cases diagnosed and operated on as tuberculosis of the peritoneum are simply chronic peritonitis, and the drainage is the cause of the mystic cure. How many are injured by the abdominal section? Many are born to die unreported. How many cases are really tubercular peritonitis which are operated on and reported on in the ordinary journal?

Finally, what about the newer treatment of iodoform? Senn uses in the abdominal cavity two drams of a 10 per cent. iodoform-glycerin emulsion and claims it has curative effects. This emulsion is smeared over the affected portions of the peritoneum. It may be noted that others believe this valueless for treatment. It seems to do good work as an interosseous and parenchymatous injection, and if so, why not apply iodoform-glycerin emulsion to the peritoneum? Tubercular peritonitis is a surface tuberculosis and it yields the most readily to surgical treatment. Is it because it is a surface tuberculosis? We must not forget that the peritoneum is a great lymph sac and the endothelial layer rests on a bed of lymphatics. Has this anything to do with the curative effect of incision and drainage? What has vis-

ceral trauma to do with it? But there is no doubt that our observations are very defective in tubercular peritonitis, for doubtless many patients recover from it of whom we know nothing, and simply because we accidentally find one and operate, we think we have discovered a therapeutic agent. The month's rest in bed deceives us by its curative effect also; we are apt to overlook that. I call attention to the view that leucocytes may help the surgical procedure to fight the battle against the invading germs. For, really, tuberculosis is a benign disease and requires but a slight shock to check its progress. It, in this respect, resembles a growing uterine myoma whose existence is easily checked by a slight shock. Inflammation seems to be, from my experiments on the peritoneum, a production of leucocytes. It is a fight of the leucocytes against the invader, whether it be Berlin blue or microbes. The object of the leucocyte, a defender of invasion, is to digest or imprison the invader. Now, since the Berlin blue can not be digested, it is encysted, surrounded. Again, when the tubercle bacilli invade the peritoneum, the leucocytes surround it, forming what are known as tubercles, *i. e.*, the tubercles of the peritoneum are composed of leucocytes which endeavor to defend the organism. If the leucocytes are well fed or sufficiently numerous they will come off conquerors. Now, when the abdomen is opened in peritonitis a reaction arises from the trauma and the peritoneum is supplied for a season with much more blood than usual. This fresh supply of blood over-feeds the leucocytes or tubercles of the peritoneum, and the leucocytes with their renewed vigor digest or englobe the tubercle bacilli, hence the recovery from tubercular peritonitis; we may be able to do this same object by a simpler surgical procedure later. However, it seems that the recovery of the tubercular peritonitis with or without surgery must be credited to the leucocytes, the defenders of animal organisms against microbial invasion or inflammation.

BOVINE TUBERCULOSIS.

Read before the Chicago Pathological Society, March 9, 1896.

BY HENRY B. STEHMAN, M.D.

CHICAGO.

Tuberculosis in cattle has become a recognized factor in the production of tuberculosis in the human family.

The weight of evidence is rapidly accumulating to show that tuberculous food is directly responsible for the transmission of this disease in many individual cases. It is stated that of the mortality of the race 7 per cent. is due to tuberculosis, but the casual observer will readily see that this is but a partial statement of facts, for we all know that many cases with sufficiently pronounced lesions to produce death, are not classed in this category. The nature of many infantile diseases and lesions of important viscera in adults are only too frequently unrecognized. They are treated as inflammations of some sort, when in fact they are nothing more nor less than genuine tubercular affections. The prevalence and fatality of the disease makes it all the more important that we should discover and if possible prevent the causes and conditions which are active in its dissemination.

It is now admitted that food from a tuberculous animal, whether milk or meat which has been infected, may produce tuberculosis, and especially is this true in infants, in those greatly prostrated from some

febrile condition of a typhoid type and in those cases predisposed to the disease.

The investigations that have been made within the past two or three years, show that tuberculosis prevails pretty generally among our cattle and especially is this the case among our dairy herds. The reports which come to us from different States emphasize the fact that the affection is not limited to any special locality. Herds have been tested in which it was found that as high as 75 per cent. were affected, though this is exceptionable; nevertheless, it is not uncommon to find as many as 30 per cent. so diseased. The statement has recently been made that in the State of California (*THE JOURNAL*, Vol. XXVI, p. 240) 15 per cent. of the cattle are infected, but this estimate is far above the generally accepted opinion of veterinarians, who tell us that about 5 per cent. of the cattle of this country are tuberculous. In our own herd we found four diseased out of thirty-eight that were tested.

The opinion seems to prevail that the disease is most prevalent among the best bred herds, but the recent reports coming from the New York Board of Health show that of those condemned, the common stock more than outnumbered all the pure breeds (*Country Gentleman*, Vol. LXI, p. 231). Tuberculosis steals upon cattle as insidiously as it does upon human beings; in fact, in its incipient stage, or even when quite far advanced, whether it involves the thoracic or abdominal viscera, or both, physical signs are of little or no avail in making a diagnosis. It is only by the use of tuberculin that it can be positively detected. The disease may involve important viscera to a considerable degree and yet physiologic functions may not be impaired or the nutrition disturbed. It is only by the use of tuberculin hypodermically injected that the affection may be recognized by any degree of accuracy. The experiments at home and abroad have only strengthened the opinion of careful observers on the reliability of tuberculin as a diagnostic measure, and while it may not yet be recognized as an infallible agent, nevertheless the difficulty lies not in the value of the agent itself, but in the lack of experience and wisdom which is necessary to interpret the conditions which follow its exhibition and correctly differentiate them from pathologic or even physiologic symptoms which they closely simulate. The value of tuberculin lies in the fact that its exhibition produces a toxemia which manifests itself in a decided temperature rise where tuberculosis exists in an incipient or moderate state of development, but in those cases where the disease is far advanced no such reaction takes place. Fortunately, however, in those cases the symptoms are so manifest that the lesion may be recognized by the usual physical signs. The best authorities tell us that a characteristic reaction after the administration of tuberculin of two degrees above the normal is proof positive of tubercular infection (*Bureau of Animal Industry*). It only remains, however, to ascertain what is the normal temperature of each individual case, for as stated, there are various conditions, such as metritis, pregnancy, heat or handling that may increase temperature and thus modify the value of the initial observations. The temperature is usually taken by the rectum; from four to six observations are made, from twenty-four to forty-eight hours previous to the injection of tuberculin.

The temperature rise occurs from nine to sixteen

hours after the inoculation, and if the toxemia is profound we find symptoms such as general weakness, coughing, animal refuses food, coat is rough, breathing is labored, forearms are extended, eyes are glassy, and in thoracic lesions characteristic signs may be easily recognized. In other cases enlarged cervical and mammary glands may also be detected. This temperature manifestation may last with slight variations for a day or so and then gradually subside. In ordinary cases the animal suffers considerable from the intoxication, and in many cases the pathologic changes are increased by the use of tuberculin, so that they pass into a rapid decline.

Where, however, no tuberculosis is present the injection does no harm as was formerly supposed. It was our experience that in the healthy cattle within forty-eight hours all the functions were normal, and in a few days the milk flow was reestablished. This limited observation is confirmed by a large array of testimony (*Pennsylvania Reports*), and consequently this objection holds good no longer as an excuse for refusing to try this test. Besides, even though tuberculin is derived primarily from the product of the bacillus of tuberculosis, it undergoes such changes in course of its preparation that the article we call tuberculin is nothing but a chemie substance, and of course can not originate tuberculosis. Recent reports (*State of Iowa*) from those who have studied the subject carefully show that tuberculosis is not transmitted from parent to offspring; this observation among cattle has long since been observed in the human family by the profession. The disease spreads among herds either by the indiscriminate housing together of healthy and diseased cattle, or the infection is produced by the milk fed to calves from tuberculous cows.

The report of the English Royal Commission appointed to investigate this subject, says: "We have obtained ample evidence that food derived from tuberculous animals can produce tuberculosis in healthy animals." It says further: "The ordinary processes of cooking applied to meat which has got contaminated on its surface are probably sufficient to destroy the harmful quality, but it would not avail to render wholesome any piece of meat that contained tuberculous matter in its deeper parts. The boiling of milk, even for a moment, would probably be sufficient to remove the very dangerous quality of dangerous milk." The Commission reports that "while the recognition of tuberculosis during the life of the animal is not wholly unattended with difficulty—nevertheless in most cases it can be detected with certainty in the udders of milk cows." But more recent investigations prove that milk may be tubercular and yet the udder of the cow show no evidence of disease.

Roth (*Mod. Med.*, Vol. IV, 12, p. 314) tested thirty-six cows which showed no evidence of disease in the udder and in twelve the milk and cream contained tubercle bacilli. Twelve pigs were fed upon the same milk and five became diseased. Twelve out of eighty-eight guinea pigs inoculated with tuberculous milk became tubercular. Of twenty-one calves fed upon the same milk eight became infected.

H. W. Conn (*Hoard's Dairymen*, Vol. XXVI, No. 51, p. 1006) states that recent statistics from abroad show that of 45,000 swine slaughtered for market 11 per cent. were found tuberculous, and that a more careful study shows that of the swine fed at creameries upon the skim milk and slime of the centrifugal machine from 60 to 70 per cent. were found diseased.

Further, it has been found that butter made from cream gathered by the separator contains more bacilli than that made from raised cream.

The specimens which I present were removed from the animals slaughtered; you will notice various structures, lungs, liver, diaphragm, pleura, mediastinal, mammary and mesenteric glands, all showing various degrees of tubercular lesion. To me, however, the most gratifying specimens are the small mesenteric glands which scarcely show sufficient tubercular degeneration to be recognized, and yet this is all the macroscopic evidence we could find showing tubercular infection. These specimens were removed from a cow 6 years old, weight 1,100 pounds, Durham. Temperature observation previous to testing averaged 101.6 degrees; the first observation nine hours after injection was 102.6, eleven hours after 104.2, fifteen hours after 105, and then it dropped to 104, varying from this to 103.2 for twelve hours.

The searching quality of tuberculin is most strikingly shown in this test, and it speaks volumes in its favor. For it is evident that if tuberculin will cause reaction in an animal so slightly affected, by its intelligent use one can with great confidence rid a herd of all infectious animals. The specimens showing the extensive distribution of tubercular nodules over the lung and diaphragm illustrates to what degree a cow may be tubercular and yet show little or no constitutional disturbance.

To my mind this was a case of unmixt infection. This cow was a Holstein-Friesian, 8 years, weight 1,100 pounds, well nourished and gave a large flow of milk. Her average temperature previous to testing was 102.3 degrees. Nine hours after injection temperature was 107, eleven hours later 107.2, thirteen hours later 106.2, fifteen hours later 105.2, the temperature gradually receding to 104, where it remained for a number of hours. Previous to the exhibition of tuberculin this cow would not have been thought of as tubercular. There were no cervical glands involved, the udder was normal and upon auscultation the signs were negative. After injection, however, auscultation revealed signs which only could be produced by a pathologic lesion such as I now demonstrate.

DISCUSSION.

DR. E. R. LECOUNT—I would call attention to the fact that not only the milk but also the meat of tuberculous cows is dangerous. In certain experiments reported by Strauss the beef from tuberculous cattle which showed nothing wrong to the naked eye, was submitted to the temperature ordinarily used in cooking such meat, and then injected into guinea pigs and rabbits, producing typical tuberculosis in which the tubercle bacilli were found. A mere inspection of the meat, therefore, is insufficient to demonstrate its harmlessness.

TWO CASES OF PERNICIOUS MALARIA WITH RELAPSE.

Read before the Chicago Pathological Society, March 9, 1896.

BY JAMES B. HERRICK, M.D.
CHICAGO.

In the reports of pernicious malaria I would direct attention to the following facts:

1. The comparative rarity in this climate of the pernicious type of malaria.
2. The somewhat unusual complication in an adult of convulsions (Case 1).
3. The occurrence in the child of convulsions oft

repeated and resembling the petit mal of epilepsy and yielding only to quinin.

4. The ready explanation of the cerebral symptoms, afforded by recent pathologic studies.

5. The illustration of the necessity of blood examination as an aid to diagnosis.

6. The course of the temperature in Case 1 characteristic of the pernicious tertian fever, prolonged stage of fever, precritical rise, etc.

7. The relapse (Case 1) with change of type to the quotidian.

8. The lesson that even yet needs an occasional enforcement of the specific effect of quinin.

COMA; FACIAL PARESIS; CONVULSIONS; RELAPSE; RECOVERY.

Case 1.—Nov. 9, 1895, there was admitted to the County Hospital to the medical service of Dr. Norden, to whose kindness I am indebted for the privilege of seeing and reporting the case, a young man who was in such a condition of stupor that no history could be obtained. Nor could those who brought him to the hospital furnish any facts concerning the duration of the illness or its past course.

The face was somewhat flushed, the skin dry, the pulse 108 and rather weak, respiration accelerated, 24 to 40. The temperature was 104 degrees F. There was no exanthem. No bruise, mark or other evidence of injury, and no focus of suppuration could be found. No enlarged glands were detected. The tongue, while moist, was heavily coated; the patient was too stupid to protrude it.

The examination of the head was negative save for a slight paresis of the facial muscles on the left side. The retina was negative. The lungs and heart upon physical examination revealed nothing abnormal. The limbs, the osseous and muscular systems were negative. The urine contained neither albumin, sugar nor casts. The only positive finding was an enlarged spleen, the edge of which was distinctly palpable, two finger's breadth below the costal arch. The temperature on admission at 4 P.M. was 104. The next morning at 2 o'clock it was 98.8, pulse 94.

Late in the evening of the same day an examination of the blood showed the plasmodium malariae. Dr. Lemke, the house physician, who made the examination, found but a solitary parasite in the four slides examined. But this was so unmistakably the malarial organism that the diagnosis was beyond question. The parasite was endoglobular, somewhat irregular in contour, filled about one-half of the rather pale red corpuscle and contained fine, actively moving, dark pigments.

November 10: In stupor; temperature normal.

November 11: 12:15 A.M., chill lasting one and one-half hours. Patient during chill did not shake violently. Axillary temperature after chill 104.2. Patient very stupid. At 8 P.M. temperature 105. Quinin sulphate, gr. xv, was ordered to be given at 4 A.M. and at 4 P.M. for six doses; also five drops of Fowler's solution three times a day.

November 12: 4 A.M., convulsion lasting about two minutes. Pulse 100; temperature 98.6, respiration 28. 2 P.M., quinin bisulphate gr. xv, given hypodermically. 3 P.M., convulsion lasting three minutes; urine negative. 6 P.M., vomited.

November 13: 4 A.M., temperature 100.2; no chill; quinin gr. xv.

November 14: 8 A.M., pulse 68; temperature 95.4 (taken twice in axilla and twice under tongue); respiration 18; vomited breakfast.

November 15: Still somewhat dull.

November 16: Considerably brighter; given clothes.

November 18: Mental condition much improved. Denies ever having had convulsions before entrance to the hospital. Says was sick four or five days before being brought to the ward. Had pain in the side and legs; vomiting; severe headache. Has no remembrance of how he came to the hospital. Does not remember chills or fever. During the summer of 1895 was sick in hospital in St. Louis. Does not know exact nature of illness. Spleen still palpable.

The record does not show the temperature between November 20 and December 2, during which period the patient was helping about the ward and kitchen. During this time he did not take quinin.

December 2: Noon, chill; temperature 104; quinin begun.

December 3: 11 A.M., chill; temperature 102.8.

December 4: 3 P.M., temperature 103.3.

December 5 to 8: Temperature normal. Patient left hospital at his own request.

This case presents several points of interest both from a clinical and pathologic standpoint.

Mode of Infection.—There is no definite knowledge of when or how the primary malarial infection occurred, though it was presumably in the south. The majority of the cases seen in Chicago are, I think, either imported malarias, drainage-canal cases, or the exacerbations of the disease in those infected long before, and in whom we are forced to assume the disease has remained latent, though what is the true nature of the so-called latency is as yet unsettled. Still, there are seen occasionally, developing in our city's midst, unquestioned cases of paludism in which one is at a loss to know where to look for the source of infection.

Temperature chart, Case 1, showing on November 11 precritical elevation of temperature, followed by pseudo-crisis. From November 11 to December 1 the temperature was normal and is not shown. The relapse is shown beginning December 2. December 5 the temperature was normal and remained so for three days, at which time the patient left the hospital. Some quinin was given by the mouth between November 10 and 11, but much of it was vomited.

Value of Blood Examination.—The case illustrates the positive value of blood examination. Without such an examination a diagnosis in a case of this character, in a supposedly non-malarial district and with no previous history would be at the best guess-work. One would be hesitating between cryptogenetic septic-pyemia, cerebral abscess, meningitis, concealed pneumonia, etc. With the blood examination the

diagnosis is a matter of certainty, treatment is clearly outlined and followed by brilliant results. We may, with reason, say that death was averted by the vigorous exhibition of quinin in this instance.

The Parasite.—While a more thorough study of the parasite would have been desirable, being prevented largely by the necessity of early administration of quinin, we may fairly conclude that the type of organism was the estivo-autumnal. The paucity of plasmodia in the peripheral blood, but one organism being found after careful search in four specimens, argues in favor of the estivo-autumnal type, where the parasite is found in far greater numbers in the visceral blood. One is scarcely warranted in asserting, from the inspection of a single endoglobular parasite, half-filling a somewhat pale red corpuscle, the parasite containing a small amount of fine pigment in active motion, that the parasite is of a certain definite variety. Yet this description fits some of the larger forms of the estivo-autumnal type better than it does the half-ripe forms of the tertian or quartan.

The Temperature.—The course of the temperature is that of severe estivo-autumnal fever. During the first attack, the severe one, the paroxysms were of the tertian type. The febrile period, it is to be noticed is the prolonged period of twenty-four hours characteristic of the pernicious forms of the disease. I would call attention also to one other characteristic of the temperature. After the chill on the morning of November 11, the axillary temperature was 104.2. Two hours later it had dropped to 102 degrees, and it rose again to reach its highest point, 105 degrees, sixteen hours later. This precritical elevation of temperature, with pseudo-crisis (calling to mind the pseudo-crisis of pneumonia) is emphasized by Marchiafava and Bignami in their description of the estival or pernicious tertian fever. Thayer and Hewetson in their monograph give a graphic representation of this same peculiar behavior of the temperature in the severe autumnal fevers.

Effect of Quinin.—The beneficial effect of quinin given hypodermatically is well illustrated by the accompanying temperature charts.

Relapse and Change of Type.—It is of interest also to note the change of type of the paroxysms during the recidivation beginning December 2. Here we see a well-marked quotidian type. The autumnal malarial fevers, whether passing under the name of pernicious tertian or estivo-autumnal fevers, are marked by an apparent lawlessness in the behavior of the temperature. This has not yet been found associated with a definite cycle of development of the parasite. The cycle may be of indefinite length or there may be various groups of plasmodia maturing at frequent intervals thus accounting for the great length of the paroxysm or the presence in some cases of a continuous or remittent fever. The quotidian type in this case may have been due to the destruction by the quinin of some of the weaker groups of plasmodia and the remaining of two groups having a cycle of twenty-four hours as in a double tertian. Thayer and Hewetson conclude as the result of their study of this form of disease that "the cycle of existence of this parasite has not been followed out in an entirely satisfactory manner" (p. 160).¹

Pathology of Pernicious Malaria.—The explana-

¹ The Malarial Fevers of Baltimore, Johns Hopkins Hospital Reports, Vol. v, 1895. A most complete bibliography of malaria since the announcement of Laveran's discovery is given in the monograph.

tion of the cerebral symptoms—stupor, facial paresis and convulsions, is to be sought in the blood vessels of the brain. The cerebral phenomena of malaria have been explained at various times on the score of congestion, of melanemia with pigment emboli in the capillaries (Planer 1854, Frerichs and others), and of endothelial swelling of the cerebral capillaries and consequent narrowing of the lumen of the vessel (Kelsch and Kiener). Since the plasmodial epoch, however, these manifestations have been regarded as due to the toxemia that undoubtedly accompanies hemic plasmodial development, or to the organic disturbances produced in the encephalon by the aggregation in the vessels of infected corpuscles.

While not denying the possible agency of toxemia in the production of malarial delirium, coma, convulsions or paralysis, one can not overlook the fact that in numerous instances there has been disclosed such plain obstruction of cerebral vessels by impacted infected corpuscles as to make it unnecessary to invoke the aid of an intoxication hypothesis. Such palpable mechanical interference with circulation must seriously alter the nutrition and consequently the functions of the brain. At times aphasia, local paralysis or convulsion point to a distinctly focal brain lesion. The physicians in our Southern States not infrequently describe cases of this sort. In the case in hand there was a slight facial paralysis. Marchiafava in a case with bulbar symptoms found occlusion of the medullary vessels by plasmodial thrombi. Danilewsky² found in the blood of a patient with paludism a large, free, semilunar form, evidently from its pigment, a hemocytozoön. In width it was nearly the diameter of a red blood corpuscle; in length it was about three times the diameter of a red corpuscle. He calls attention to the possibility of a mechanical obstruction of a capillary or arteriole by such a large body, with marked consequences if the vessel were in the medulla. So that circulatory obstruction would seem to be the cause of many of the cerebral symptoms in pernicious malaria.

The Italians, Marchiafava and Celli, and Bastianelli and Bignami have called attention to the fact that the infected corpuscles red and white, particularly in the cerebral vessels, can be seen lining the vessel wall, perhaps as Mannaberg³ suggests because of a certain acquired viscosity. Circulatory obstruction and thrombosis would thus be favored. Mannaberg depicts from some of Golgi's specimens, cerebral vessels lined and filled with infected corpuscles both pigmented and unpigmented. Dock⁴ also shows a microphotograph of a cerebral capillary with numerous pigmented corpuscles.

Minute hemorrhages from vessels thus thrombosed are mentioned by many, *e.g.* Bastianelli and Bignami. Mannaberg, Golgi, Dock, Councilman and Barker. Attention may be called, in passing, to the finding of similar capillary and arteriolar thromboses in other than the cerebral vessels. In cases where gastric symptoms have been pronounced, the vessels of the stomach have been found plugged with infected thrombi.⁵ The same condition has been found in the intestinal vessels. It is still unsettled why, in a given case, the infected corpuscles select the vessels of a

certain organ or certain vessels of one organ and shun others.

Rarity in Chicago.—So far as I can learn this is the second case of pernicious comatose malaria admitted to the County Hospital in the last few years, *i.e.*, since systematic examination of the blood has been made in all suspected cases. During this time scores of patients with malaria, chiefly from the drainage-canals district, have been seen in our wards.

COMA; EPILEPTIFORM CONVULSIONS; RECOVERY.

This case was seen in consultation with Dr. M. H. Stephens, to whom I am indebted for many of the facts.

Case 2.—Louise T., 5 years; native of Canada. Said to have lived in malarial district. Mother neurotic; father died of cerebral hemorrhage. Frail, nervous, poorly nourished as a babe. "Brick-dust" in urine. At 15 months, convulsions lasting from 10 p.m. to 7 a.m., followed by fever which mother said was "typhoid pneumonia." Dec. 31, 1894, 10 p.m., convulsion followed during night by a second one. Regained consciousness only after many hours. History of fever somewhat doubtful. Many attacks of petit mal at this time. These are said to have continued with more or less frequency until the fall of 1895.

Oct. 17, 1895, at noon, seized on the street with convulsion. Regained consciousness at 8 p.m. Dr. Stephens administered chloroform to ward off what appeared to be threatening convulsions.

October 18: Temperature a.m. normal.

October 19: 9:30 a.m., chill; temperature at noon 104.5.

October 20: Forenoon, chill; temperature 103.5. Between 4 and 6 p.m., normal.

October 21: Temperature 105.2; no further chills; temperature irregular from this on, varying between normal and 104.

October 22: Patient seen in consultation with Dr. Stephens.

Examination.—Mind clear, urine negative. All organs negative save an enlarged and plainly palpable spleen. No typhoid spots. Next day, October 23, blood examined and a single hyaline endoglobular body with small amount of blackish pigment found: this believed to be the malarial plasmodium.

October 26: Temperature 101 degrees at noon, following this normal. The later history of the case is best learned from Dr. Stephens' letter of Dec. 23, 1895:

Dear Dr. Herrick:—Your inquiry regarding Louise T. is just received. I am very glad to say that the child is doing well. The quinin, two-grain doses, three times a day, was continued for about a week. Then the dose was reduced. The fever rapidly disappeared and the little girl was out in about two weeks. She had no "petit mal" attacks from time of her severe convulsion at the beginning of her illness, until about two or three weeks ago. She had had no quinin for about a month. Had been on syr. ferri iod. and syr. hypophos. co. About two or three weeks ago she began having mild attacks beginning with one or two a day and increasing rapidly until she had from twelve to fifteen during the day. For a time I kept her on sod. bromid and also liq. sodii arsenitis, with no effect. Began giving quinin, sulph. gr. i three times a day about a week and a half. She improved rapidly and is now free from the mild attacks.

Yours sincerely, M. H. STEPHENS.

I regard this case as malaria for the following reasons: 1, lived in malarial region in Canada; 2, the previous febrile attacks attended by convulsions from which recovery had taken place, may well have been malarial, their repetition tends to exclude masked exanthemata, pyemia, malignant endocarditis, cerebral abscess, etc.; 3, remittent fever and chills; 4, enlarged spleen; 5, exclusion of other diseases; 6, yielding to quinin; 7, the detection of the plasmodium.

It is perhaps assuming more than can be proven to say that all the epileptiform attacks were due to malaria. But it seems warrantable to assume that in a neurotic child, the malarial infection acting upon an irritable cortex was the exciting cause of an outbreak of an otherwise dormant epilepsy. The prompt response of the petit mal to quinin, when bromids, etc., had failed, is very significant of a persistent mild

malarial toxemia, that might be entirely symptomless and overlooked were not the child predisposed to cortical irritation.

Krafft-Ebing⁶ records a case resembling in some particulars the one I have reported. The case is of such interest that I give a synopsis of it:

Male, 29 years, rheumatic, with mitral lesion. August, 1886, intermittent fever, treated for three months; no epilepsy, no delirium. June, 1888, relapse. During fever fell and injured right mastoid process. Since then muscae, dimness of vision. Two days after injury slight attack of unconsciousness. July, two attacks. August, two attacks. September: Daily attacks of unconsciousness with convulsion; fever and delirium; no aura; no scar tenderness; cranial nerves, retina, sensibility, urine, all negative. Slight amblyopia; no hysterical stigmata. Spleen enlarged and easily palpated. February 17, 1891: Chill and convulsion. Up to March 8, there were daily several attacks with convulsions. The delirium that played a prominent part is accurately described. Fever persistent. March 8: Quinin, gr. v daily. March 16: Quinin, gr. xv daily. Temperature gradually fell to normal, spleen decreased in size and on April 1, patient left hospital apparently well.

April 10 reentered hospital with large spleen, and fever. Repetition of epileptiform attacks with delirium. Recovery May 15, under quinin.

Symptomatically this was an epileptoid neurosis. Naturally traumatic epilepsy had to be considered. Krafft-Ebing regards it as a case of masked malaria in which an injury to the head determined the point of the malarial attack, making of the brain a *locus minoris resistentiae*. Unfortunately no blood examination was made.

DISCUSSION.

DR. L. L. MCARTHUR—I would ask if in looking up the literature of the subject you have found anything in regard to suppression of urine by occlusion of the vessels of the kidney from the plasmodium? The reason I ask the question is, that, during the present week, I have had a case of malaria poisoning of the pernicious type referred to by Dr. Herrick, develop in a patient convalescing from a hernial operation at the Chicago Hospital, under the best of sanitary conditions. It is quite inexplicable how it may have originated. The temperature ranged extremely high, 103 to 105.5; the blood was laden with plasmodia, as shown by Dr. Frank Johnson. There was persistent vomiting, with pain in the back so marked that my attention was turned chiefly to the kidneys; the quantity of urine voided being eighteen ounces in twenty-four hours, heavily laden and highly colored; no albuminuria, no blood, no casts. But the plasmodium being found in the blood and the fever yielding to quinin, made me think that it was a malarial affection of the kidney. Possibly an embolic effect of the renal vessels, as suggested by the paper.

DR. SANGER BROWN—I would ask Dr. Herrick if in looking up the subject he has found that the plasmodium is discovered in patients who are not subject to malaria, or who have none of the positive symptoms of the disease. I saw in consultation a month or two ago an interesting case in which a man of 60 had attacks of unconsciousness, which were repeated several times in the course of three or four days. In the intervals he was not quite clear mentally. The question arose as to whether they were preliminary to a stroke of apoplexy, that is, small hemorrhages, or not. His son, who is quite an accomplished pathologist, made a careful examination of the blood and found the plasmodium in several slides. About a week after this the man had an attack of apoplexy which was fatal. If the blood had not been carefully examined in this case and the plasmodium found, it doubtless would not have been thought of attributing the symptoms to malaria. It would be regarded simply as the premonitory or preliminary light attacks of apoplexy or cerebral hemorrhage. I would also ask whether in the comparative number of plasmodia found in the accessi-

ble blood the examination bears any constant relation to the severity of the malarial symptoms, assuming that the cases which have been cited were cases due to malaria. If the symptoms were due to malaria, it would seem that they were severe, and the plasmodia ought to have been very numerous.

DR. D. W. GRAHAM was reminded by Dr. Herrick's paper of an experience some years ago before the plasmodium had been demonstrated. The patient while spending some weeks in Louisiana, when malarial fever was very common, had daily chills, and on his return became comatose and hemiplegic. He was given large doses of quinin with the hope that his condition was due to malaria. Although thought to be a case of cerebral hemorrhage by the consultant, consciousness soon returned and the hemiplegia passed away with the exception of a slight weakness of the afflicted arm. The effect of the plasmodium on the cerebral circulation, as given by Dr. Herrick, would seem to explain in a very satisfactory way this and many similar cases.

DR. WM. HESSERT—Dr. Herrick has brought out many important points in his paper, one of which is the examination of the blood in all cases of doubtful diagnosis, and even in cases where the diagnosis is more or less positive. Having had occasion to examine blood very frequently, I have come across phenomena, an explanation of which I have been unable to offer. For instance, I have seen minute particles of freely mobile material consisting of fine granules, these particles being in active motion. I have found bodies of different sizes and shapes in the blood. Some were dumb-bell shaped, others more or less biscuit shaped, and still others that were spherical. They were evidently not blood-plates, being opaque and yellowish in color, and not collected in clumps. The motion of these bodies was rapid, and I have been unable to tell whether they have ciliary appendages or not. In some instances I have found cilia, and for instance some in my own blood had cilia, and I certainly had no malaria. I have been unable to stain these bodies, which is an important point. I would like to get information from Dr. Herrick as to whether he has seen these phenomena himself. Some of the granules I speak of may be explained in this way, namely, I have seen eosinophilous cells in fresh slides break up, the granules becoming free and scattering through the field; but the nature of the other bodies I have been unable to determine.

DR. ROBERT B. PREBLE—My remarks are suggested by the question asked by Dr. Brown as to whether the malarial plasmodia have ever been found in the blood of patients who show no symptoms of malaria. Without answering this question, I would like to draw attention to a few bodies found in the blood, which may be readily mistaken for the plasmodium. The malarial plasmodia, in their typical forms, are easily and positively recognized; but it is not always easy to say, that a certain body which you see in the blood, is or is not a plasmodium. We gather from the wording of Dr. Herrick's paper that he was somewhat in doubt as to the malarial nature of the second case and he expressed himself very guardedly as to the nature of the body found in the blood and believed by him to be the plasmodium of malaria. A not infrequent error is to mistake a cremated red corpuscle for a plasmodium. One often sees a red blood corpuscle with a number of small clear circles arranged about the center of the disc of the corpuscle. The border of the disc is unchanged. This gives one an appearance somewhat resembling the sporulation form of the plasmodia. The difference, however, is so great that error is impossible, when the true segmentation figures have been seen once. Another thing, which may also lead to error, is the movement of the granules of the protoplasm of the white corpuscles. This motion is sometimes as active as that of the granules of the plasmodia and resemble it perfectly. The differences between a white corpuscle and a red containing a plasmodium, are so great that error is possible only when one forgets that the

⁶ Zur Intermittem-Larynia, Wiener Med. Presse, 1892, 1-4.

granules of the white corpuscle move at times. Dr. Hessert has mentioned the fact that auto-mobile bodies are often found in normal blood. The knowledge of this fact is not so general as it should be. These bodies show a great variety of forms and are often so active, that the slide must be kept in constant motion to keep them in the field of the microscope. They are, no doubt, frequently mistaken for the plasmodia. Before closing, I would like to draw attention to a very common error in the method of examination of the blood for plasmodia. It is common practice to dilute the blood with a solution of methyl blue, in this way staining the plasmodia. I believe that this is a fruitful source of error, for while it stains the plasmodia, which can be recognized as easily unstained, it also stains other bodies which can now be mistaken for the organism. Thus a member of the profession, who holds and deserves a high position, showed me a lymphocyte stained with methyl blue and which he believed to be a plasmodium. That error would not have been made if the specimen were unstained. This error is only an example of the many which may and do occur with this method of examination and I agree with Thayer and Hewetson that it is best to examine fresh specimens unstained.

DR. HERRICK (closing).—In answering the question of Dr. McArthur, I would say that plasmodial emboli have been found in the kidneys, chiefly, I believe, in connection with hematuria. As to the question asked by Dr. Brown with regard to finding plasmodia in non-malarial blood, I think that it is almost a contradiction in terms to say that plasmodia can be in the blood without malaria. We must assume, I think, that if a patient has the plasmodium in his blood he has malaria. Yet he may be free from symptoms. The question of latency of malaria is one that is by no means clearly understood. In patients who are entirely free from fever, who have been cured by quinin, the malarial plasmodium can sometimes be detected, and particularly are the crescent forms of the plasmodium persistent, long after all febrile manifestations have disappeared. This will call to mind the analogous finding of diphtheria bacilli in the throat in cases of diphtheria that clinically are cured, as well as the finding of tubercle bacilli in the sputum of those without symptom or sign of phthisis. The case which Dr. Brown speaks of might possibly be one of malaria with a thrombus due to infected blood corpuscles, a hemorrhage as the result of obstruction of a blood vessel by such corpuscles, an accidental combination of malaria and cerebral hemorrhage, or a mistake in recognizing the plasmodium.

The second question Dr. Brown asks is whether there is a relation between the number of plasmodia found in the blood and the malarial manifestations. That may be possibly true with regard to tertian infection, but with reference to the estivo-autumnal type, there is not that relation. The visceral blood, for instance, will contain a multitude of plasmodia, while the peripheral blood may be examined repeatedly and the plasmodia will be found absent. In the County Hospital case, the first one I reported, an unusually grave one, there is no question with regard to the diagnosis; yet in the blood on four slides only one plasmodium was found after careful examination. Dr. Graham's case may have been one of the severe cases of malaria with obstruction of a blood vessel from infected corpuscles.

Dr. Hessert and Dr. Preble have called attention to a very important point, and it is gratifying to see two gentlemen who have done so much in examining the blood frankly admit the great difficulties in recognizing plasmodia. As Dr. Preble says, when we have a typical ripe tertian organism it is recognized beyond the shadow of a doubt, yet there are many forms that are difficult of recognition, particularly the smaller ones that are but half developed, and the hyalin forms. And there are many things that can mislead the physician in examining the blood. I have seen in unstained specimens the eosinophilous granules referred to by Dr. Hessert. The coarse granules

of the eosinophilous cells, when scattered about, resemble hyalin bodies. But staining brings them out clearly with acid rather than with an alkaline dye. They can readily confuse one. There are other forms that are apt to cause confusion, *e. g.*, the blood plates.

I was interested in reading an article by Paltauf (*Centralblatt f. Bakt. und Par.* xi, 1892, p. 95), in which he clearly demonstrates that several cases of malaria in children, reported by Hochsinger, were not cases of malaria at all. Hochsinger submitted specimens to Paltauf for examination, and he came to the conclusion that in every single specimen where Hochsinger had found plasmodia, he had mistaken blood plates for the plasmodia. I am glad that Dr. Preble brought up the question of staining a fresh specimen of blood. It seems to me it is a dangerous method of examination unless we have an absolutely fresh and carefully filtered staining fluid, and one that we know contains no foreign material. It is certainly wrong to carry about in the pocket a methyl-blue solution for several weeks, then place a drop of the methyl blue on the tip of the finger, prick through that, and thus get a specimen of the blood. Many of these solutions will contain microorganisms, as well as precipitates, and the examination in that way can not be as reliable as by the examination of a fresh specimen of blood.

REMOVAL OF THE UTERINE APPENDAGES FOR UTERINE FIBROIDS.

BY FRANKLIN H. MARTIN, M.D.

PROFESSOR OF GYNECOLOGY POST-GRADUATE MEDICAL SCHOOL OF CHICAGO; SURGEON TO WOMAN'S HOSPITAL.

Batley, Tait and Hegar independently conceived, performed and contributed to modern surgery the operation of removal of the uterine appendages. In 1865 Batley "conceived" but did not publish "the idea of producing an artificial menopause for the remedy of disease." His idea was published in 1872. Hegar operated on the first case with the object of establishing an artificial menopause, a few days before Aug. 1, 1872, the memorable date of Tait's first operation for the same purpose. Batley did his first operation just sixteen days later, or Aug. 17, 1872. Thus the time was ripe and three great men of three great nations, separated by thousands of miles, discovered the fact, independently of each other, and shook the tree of progress which has resulted in such an abundant harvest.

The removal of the appendages for the cure of fibroids of the uterus is based on the facts: 1, that removal of the uterine appendages eradicates the part of the economy in which resides the organ or center of menstruation and produces an artificial menopause; 2, that removal of the uterine appendages accomplishes a reduction of the direct blood supply to the uterus and thereby produces atrophy by depleting the organ.

ARTIFICIAL MENOPAUSE.

It is yet an unsettled question where the exact seat of control of menstruation is located. It is not the province of this article to enter into the heated discussion as to whether this remarkable center lies in the ovaries or whether it is situated in the nerve structure of the Fallopian tubes. It is enough for us to know that the menstrual center, wherever it lies, is eradicated, in the maximum proportion of cases, when every vestige of both ovaries and Fallopian tubes is removed. It is well that such is the case, because it would be an awkward and incomplete operation which would seek to leave either the ovaries or the tubes

These two organs have a function which of necessity is incomplete without both of them. It would be difficult to remove the ovaries without interfering with the circulation and position of the tube. It would be equally impossible to remove the tubes without interfering with the circulation and function of the ovaries. Then, too, a much more secure and desirable pedicle can be obtained when both organs are included in a ligature than is possible if but one of the organs is selected. Then, as the function for which each of these small organs is designed is dependent upon both, and the removal of both is easier and therefore safer than the removal of one of them, and when we take into consideration the liability of either of these organs to become diseased, if not removed when opportunity permits, there seems to be no further reason why both organs should not always be removed when it is desirable to produce an artificial menopause.

REDUCTION OF BLOOD SUPPLY TO THE UTERUS.

In a previous article we discussed the blood supply to the uterus. We found that the organ depended upon two sets of arteries for its nourishment, the uterine arteries and the ovarian arteries (Fig. 1). The normal ovarian arteries are a trifle more than half the size of the uterine arteries. They supply the ovaries, the tubes, the fundus of the uterus and anastomose

FIGURE 1.

with the uterine arteries which course along the sides of the uterus giving off frequent horizontal branches to the uterus. By referring to Fig. 1 it can readily be seen that the ovaries and tubes may be removed without including the main channel of the ovarian artery. Such a method of operating would deprive the removal of the appendages for the cure of fibroids of one of its chief features of benefit, viz., the reduction of blood supply to the uterus. For that reason special care should be maintained by operators adopting this procedure to include in all cases the main channel of the ovarian artery in their ligature. By tying this artery on both sides the large abnormally developed uterus is instantly deprived of one-third of its blood supply.

Dr. Byron Robinson, after witnessing my operation of tying the broad ligament from the vagina, recognized the value of this principle of cutting off blood supply to fibroid uteri, and afterward applied one of the principles of my operation through an abdominal incision, after having first removed the appendages, by tying the uterine artery as it courses up the side of the uterus to join the ovarian artery.

INDICATIONS FOR REMOVAL OF UTERINE APPENDAGES FOR FIBROIDS.

But a few years ago this was the operation of selection for the relief of uterine fibroids when an operation of the severity of a laparotomy was deemed a necessity. It is seldom performed at present except as an operation of *dernier ressort*, when laparotomy has been instituted with the object of removing the tumor and uterus and, because of contraindications, the latter operation is found inadvisable. The reasons for this change of position are:

1. The operation of vaginal and abdominal hysterectomy has been so perfected that in patients of ordinary strength, with tumors without severe complications, the mortality of hysterectomy is not materially greater than that of double oöphorectomy.

2. The operation of removal of the appendages fails about three times in thirteen recoveries to materially reduce the size of the tumor, and fails in one case in thirteen recoveries to produce an artificial menopause; while hysterectomy on the other hand is absolutely sure of curing every case of fibroid of the uterus, which recovers from the operation both of hemorrhage and tumor.

This materially narrows the field of operation which has done more to develop modern surgery than any other discovery of modern time, except the discoveries of Lister. The very enlightenment which it has created helps to make it obsolete. The operation now, in the hands of expert abdominal surgeons, is limited to cases: 1, where for some reason the operation is demanded because of prejudice against sacrificing of the uterus; 2, in cases where for some good reason quickness of time in operating is desirable; 3, in cases where unusual complications are revealed when the abdomen is opened which make hysterectomy impracticable; 4, in cases of small bleeding tumors in weak women who are near the menopause; 5, in cases of small hemorrhagic fibroids in weak women in whom laparotomy would not ordinarily be indicated but which are complicated with disease of the appendages.

THE OPERATION.

An abdominal operation is properly divided into five parts: Incision, removal of pathologic material, drainage, closure of incision and dressing.

The Incision.—After the skin has been prepared as described in Article VI, and sterilized towels have been placed around the field of operation, the patient is thoroughly anesthetized with ether and the operating corps is in its place; the operator standing on the left side of the patient, with a sharp scalpel makes an incision from above downward in the median line, from about two inches below the navel to two inches above the upper margin of the pubis, an incision about three inches in length. This incision should be unhaggled and should extend in depth through the skin, superficial fasciæ, the fat between the superficial fasciæ down to the deep fasciæ which immediately covers the muscles. In experienced hands but one stroke of the knife is necessary for this. If the hemorrhage is but venous, dry sponges only are necessary to keep the wound dry. If there are any arterial points of bleeding they are caught in the points of forceps by the assistant. The operator by another stroke of the knife incises the white deep fasciæ, and if this incision is through the linea alba, the subperitoneal space is entered, as will be indicated by the

bulging fat of this space. If the incision is to the right or left of the line the muscular coat of the abdominal wall will be exposed. The muscles are then separated by the handle of the scalpel in a stroke from above downward which brings into view the subperitoneal fat. The knife is carefully drawn over this from above downward, and this followed by a sweep of the scalpel handle separates the fat and subperitoneal tissue down to the peritoneum. The peritoneum is now caught in two catch forceps which are held up and separated laterally so as to present a sharp elevation of that membrane. This is carefully incised with the knife. When the peritoneum is opened it will be indicated by its sudden elevation in consequence of the entrance of air. An experienced operator will frequently open an abdomen carefully in thirty seconds. If it is done well it matters little if it takes five minutes. It is not necessary to seek for the linea alba if it does not happen to lie directly in the center of the superficial incision. It is more important that the wound should be direct and the different layers parallel than that the muscles should not be disturbed. When the peritoneum is opened between the forceps the index finger should act as a director above and below the opening and the peritoneum incised with scissors the full length of the wound, being careful not to wound the bladder below.

FIGURE 2.

Next attach the peritoneal edges of the wound at the center of the incision on either side to the deep fasciae with small catch forceps. This prevents peeling off the peritoneum from the parietes in any subsequent manipulations.

Exploration.—With the index finger of the left hand I now make my exploration of the abdominal viscera including the appendages. First the uterus is sought as a central landmark. From the uterus the finger is first swept to the left side along the Fallopian tube from the horn of the uterus. Just below the tube and above the broad ligament is the ovary. The opposite side is rapidly explored in the same manner. The exploration takes into consideration the size and position of the fibroid uterus, adhesions, the condition of the appendages, the possibility or feasibility of removing them and any abnormal developments.

Removal of the Appendages.—Our object, it must be remembered, in the removal of these organs must be to remove completely every vestige of ovary and tube and the thorough ligation of the main channel of the ovarian vessel. When the uterine tumor is not large, or if it has not developed into the broad ligament so as to spread out its folds and make it tense, it is an easy matter to ligate off the tube and ovary with one ligature. This is accomplished by lifting

the tube and ovary with the loose broad ligament and making a pedicle of the infundibulo-pelvic ligament (Fig. 2 *a*), the ovarian ligament (*b*) and the Fallopian tube (*c*). The ligature No. 10 braided silk or No. 8 antiseptic catgut threaded in a round non-cutting needle is placed around the pedicle, never through it except as it penetrates and surrounds a portion of the infundibulo-pelvic (Fig. 2 *a*) and the ovarian (*b*) ligaments in order to prevent its slipping over the edge of the stump. If the ligature is allowed to transfix the pedicle at any other place than through the firm ligamentous tissues of the two ligaments mentioned, it is liable to produce venous oozing into the loose subperitoneal tissue beneath the constriction of the pedicle, resulting in small hematomas which frequently prove troublesome. After the ligature is placed the ovary and tube are drawn well up and the strand of silk or catgut is tied firmly, first with a double twist knot and then two single twists

FIGURE 3.

FIGURE 4.

and the ends cut short (Fig. 3). A pair of snap forceps is then placed on the pedicle outside of the ligature and the pedicle is severed about one-fourth inch from the ligature, the stump cauterized or rendered sterile with some strong antiseptic, this antiseptic removed by a moist sponge and the pedicle dropped.

If the uterus is considerably enlarged or if it especially develops into the broad ligaments, it is impossible to tie off the appendages of each side with a single ligature. This is because the loose folds of the broad ligaments of which the pedicle is ordinarily constructed, have been occupied by the enlarged fibroid uterus, and the ovary and tube are each flattened out on the surface of the tumor and are held fast by the peritoneum, which ordinarily acts as a mesentery to each, Fig. 4. Under such a disposition of affairs or any modification of it, the ovaries and tubes should be tied off by first ligating the neck of

the tube as near the uterus as possible after anchoring the ligature by a twist around the utero-ovarian ligament (Fig. 4 *a*); second by ligating the broad ligament outside the fimbriated extremity of the tube deep enough to include the ovarian artery, anchoring the ligature by a twist around the infundibulo-pelvic ligament (Fig. 4); third, after removing the tube and ovary the two peritoneal edges representing the broad ligament to which the tube and ovary are attached between the two ligaments already placed, should be united from one pedicle to the other with a running stitch of fine antiseptic catgut. This makes a perfect exsection of the appendages, and leaves the peritoneum perfectly closed with no tension on either of the pedicles (Fig. 5).

DISEASED APPENDAGES.

All cases, unfortunately, are not typical like the ones we have described. We often meet with diseased appendages when opening the abdomen for the removal of these organs in cases of fibroids of the uterus. A pyosalpinx, or an ovarian cyst, or abscess of the ovaries are often encountered. Almost invari-

FIGURE 5.

ably when these things do exist, localized peritonitis has rendered them adherent to surrounding tissues, the uterus, omentum, intestines or the peritoneum of the broad ligament.

When these complications exist, and we have decided upon the removal of the appendages for the treatment of the fibroid, we have before us the problem of enucleation and excision of the diseased and adherent organs. The enucleation of an enlarged pyosalpinx, or an ovarian abscess, or a tubal ovarian abscess, or adherent appendages the result of an old peritonitis where pus is no longer present, is accomplished in practically the same way. When the abdomen is explored the abnormal condition of affairs immediately becomes apparent. Frequently there is an inextricable mass; occasionally the outlines of the tube and ovary can be traced and they simply appear as enlarged adherent semi-fluctuating cysts; while rarely, the appendages, not materially changed from their normal size, will be firmly imbedded and adherent.

I begin my enucleation in these cases, by passing the index finger of my left hand, with the palmar surface directed forward, down behind the isthmus of the tube just as it is given off from the horn of the uterus, hugging closely the body of the uterus until I have reached Douglas's cul-de-sac. As a rule, at this place I will find a line of cleavage, as indicated by the adhesions between the tube and the uterus and the ovary, and the intestines and omentum posterior to the ovary and tubes. This line of cleavage, which as it gives way feels like two pieces of strong paper which have been stuck together with fresh mucilage giving way before pressure of the fingers between them, can be followed rapidly, first with one finger, then with two or more, until the whole adherent tube and ovary are freed and lie ready to be ligated off in the palm of the hand. This is the happy result in the majority of cases.

In a few cases, especially after long standing disease, the adhesions are strong and well organized. Here great care and patience must be exercised, in order not to go into an adherent bowel, or to the other extreme and leave a portion of the stroma of the

FIGURE 6.

ovary or a portion of the tube which may be just enough to prevent the menopause and thus make our operation a failure. Here, when the line of cleavage fails to yield readily, it is well to place the patient in the Trendelenburg position and separate the adhesions after exposing them to sight. With this precaution and the exercise of considerable care in manipulation it is seldom that one need fail to accomplish an enucleation.

When these adherent masses are once dug from their beds the stumps, after ligation, should be rendered perfectly sterile by the application of the actual cautery or strong chemic antiseptics. The parts should then be dried, and where it is practicable the raw surfaces should be covered with peritoneum.

Drainage. If there is oozing from the raw surfaces caused by the enucleation, a glass drainage tube should be placed in the cul-de-sac of Douglas, the lowest point of the pelvis, while the toilet of the peritoneum is being completed and the abdominal sutures

are being inserted. Before the abdomen is closed the tube should be pumped out in order to ascertain if there is more blood oozing from the peritoneal surfaces than would naturally be taken care of by the peritoneum. If more than a couple of drams of pure blood accumulates in the few minutes that are required to make the toilet and insert the sutures, the tube should be allowed to remain, and the sutures tied so as to enclose it snugly. The tube should not be larger than an ordinary lead pencil, or about one-quarter of an inch in diameter. It should be long enough to project about one inch above the wound (Fig. 7). The abdominal dressings are then placed upon the wound around the tube and secured by sterilized muslin bands which are pinned to broad adhesive straps fastened to the sides of the abdomen at some little distance from the wound. Over the top of the tube is slipped a piece of rubber dam (Fig. 6 *a*) about 12 inches square, the tube penetrating the center of the sheet rubber. The tube is then pumped out with a small glass syringe with a long rubber nozzle which will reach to its bottom (Fig. 7). After finally emptying the tube a long narrow strip of sterilized gauze is carried to the bottom of it with a straight metal sound, a small amount of the same gauze is left as a loose dressing over the end of the tube, over this is folded the rubber dam and fastened with a sterilized safety pin, and over all this is placed a liberal dressing of sterilized cotton and finally over this a snugly applied bandage of sterilized cotton.

FIGURE 7.

Now when it becomes necessary to exhaust the drainage tube in an hour or two hours, it will not be necessary to disturb the wound dressing at all. The bandage is unfastened, the layers of cotton parted in the center and the rubber dam opened and spread out on the cotton, the capillary drain of gauze removed and the tube exhausted by means of the syringe, another strip of gauze inserted, the rubber dam refolded and pinned and the external dressings readjusted.

I go into the detail of my method of caring for a drainage tube in order to justify myself for using it. As understood by the majority of good surgeons, it is really a dangerous means of draining. But a few weeks ago, in a discussion in a prominent society on the subject of abdominal and pelvic surgery, I heard a surgeon of no mean repute condemn the glass drain and the suction pump, in unmeasured terms, when by his very language, he demonstrated his ignorance of the whole matter by saying that it was necessary to uncover the abdominal wound every time that the tube is exhausted. It is not necessary to uncover the wound at all to dress a glass drainage tube. It is not necessary to infect a glass drainage tube when uncovering it to exhaust it with the suction syringe, if the one doing the work is trained and competent. The nurse should be well trained. She should wash her hands to surgical cleanliness before loosening the bandage or removing the cotton over the end of the tube. She should rinse her hands in 1 to 1,000 bichlorid solution before unpinning the rubber dam; she

should again rinse them in bichlorid before removing the capillary drain; she should take the glass syringe with its rubber nozzle out of a pitcher of 1 to 1,000 bichlorid solution, rinse it quickly in sterilized water, rapidly exhaust the tube, and eject the fluid into a small glass graduate which has just been removed from an antiseptic solution; when the tube is dry she should take the steel sound out of a dish of bichlorid solution, a strip of gauze out of a fresh supply from a sterilized package and insert it to the bottom of the drainage tube. She should again rinse her hands and then rapidly close the tube and replace the dressings. Such a procedure requires two minutes if done by an expert and intelligent nurse. I will agree with everybody that this kind of drainage can not be carried out by an ordinary nurse. But when well attended to it is the most satisfactory method of keeping dry the free abdominal cavity that we are as yet acquainted with.

CAPILLARY DRAIN.

Occasionally after extensive enucleation of diseased appendages we may be so situated that we have no experienced nurse to leave in charge of a glass drainage tube; at the same time we *must* drain, and must drain in a manner that the after-care of the drain can be attended to by one of little experience. In these cases combined capillary gauze and tubular drain, through the Douglas cul-de-sac, may be resorted to. A rubber tube one-quarter inch in diameter and about twelve inches long, and a quantity of sterilized iodoform gauze in eight inch strips cut the strong way of the gauze without knots, are selected. After insuring thorough cleansing of the vagina the operator, guided by an assistant's finger in the vagina, penetrates the posterior cul-de-sac into the vault of the vagina with a pair of sharp pointed scissors. The scissor blades are then opened and between them from above downward, on a pair of forceps, is carried an end of the strip of gauze and the rubber tube. The assistant grasps these in the vagina and makes gentle traction on them. The operator then loosens his grasp and catches the abdominal end of the tube with a pair of catch forceps. The tube is then drawn through until from two to four inches of its upper end, according to the extent of drain required, is left in the abdominal cavity. Enough of the gauze is drawn through to make a loose packing for the vagina. A small bunch of the gauze is left in the abdomen in the cul-de-sac, around the end of the rubber tube. It is loosely packed so that it will remain in the position in which it is first placed. The abdomen is then closed in the usual manner. The vaginal end of the drain is arranged by cutting the tube off at the vaginal outlet; and over the vulva and the end of the gauze is placed a liberal pad of loose sterilized dry strip gauze. Orders are given to change this outer gauze as often as it becomes moist. When at the end of twelve to twenty-four hours there is little drain, a portion of the gauze may be withdrawn from the vagina, and if the drain has been slight the tube may be removed at this time. In twenty-four hours longer, if the drain is still small or none at all, the drain may be completely removed. After the gauze has been removed, a liberal vaginal drain of gauze may be carried on the end of a forceps to the vault of the vagina. This may be removed in twenty-four hours. After this nothing further is required but an occasional vaginal antiseptic douche. If drainage is profuse after twenty-four to forty-eight

hours the gauze drain should be withdrawn more slowly.

Closing abdominal Wound.—I favor any method which will coapt all the tissues of the abdominal wound in the exact relation and to the same extent that they were originally. This can be accomplished by including all the tissues, skin, fat, superficial and deep fascia, muscle, subperitoneal fascia, and peritoneum in a row of silkworm gut sutures placed one-third of an inch apart. If I have some of my own specially prepared antiseptic catgut at hand, I frequently sew the peritoneal layer separately with a running thread of the gut and then include the remaining layers in the row of silkworm gut. This is especially desirable if one has a long wound in a hemorrhagic patient. It completely closes the abdominal cavity from any oozing from the abdominal incision. It also obviates the necessity of the silkworm gut sutures entering the peritoneal cavity, thus removing the remote danger of adhesions of the abdominal viscera to the points of peritoneum penetrated by the stitch, and danger of septic material gaining entrance to the peritoneal cavity along the route of the stitch, in case of external skin or mural suppuration. I am careful to include all the tissues of my wound in order that the abdominal walls after incision will be as thick at the wound line as at any other position. If it is not, there will be a concavity at this point on the peritoneal surface which will act as a point of resistance, and which will favor abdominal pressure on the wound and from which ventral hernia is more liable to result.

Before tying the silkworm gut sutures, I render the wound aseptic by washing thoroughly with 1 to 1,000 bichlorid solution (employing care that none of the poison enters the peritoneal cavity) and finally rinsing the wound with sterilized water. After tying the main sutures of the wound I always put in superficial stitches of fine silkworm gut wherever they are necessary in order to insure coaptation of the skin edges.

Dressings.—Sterilized iodoform powder mixed with boric acid is dusted over the wound. Loose sterilized strip gauze is placed over the wound, and several inches around it, and over this is placed a dozen thicknesses of sterilized sheet gauze. This is held in place by sterilized muslin straps which are pinned to broad bands of adhesive straps attached to the skin on the outer borders of the abdomen. This prevents the dressing from becoming displaced by any movements the patient may make, and it also supports the wound and takes the strain off the sutures. Over this is placed an abundance of sterilized cotton and over the cotton in turn is placed a snug abdominal bandage with a perineal T to keep it in place.

AFTER-TREATMENT.

For detail after-treatment I must refer the reader to my article which appeared in the JOURNAL two weeks ago.

Dressing the Wound. The wound is not disturbed until the fourth day unless there are symptoms indicating that it is not doing well, viz., pain, fever, etc. At the end of the fourth day the nurse uncovers the wound carefully, washes it thoroughly with alcohol, and 1 to 2,000 bichlorid solution equal parts, with a wad of sterilized cotton on the end of dressing forceps. It is then dried carefully and redusted with sterilized iodoform and boric acid. It is then re-

covered with fresh sterile gauze. On the seventh day the same process is repeated and the stitches removed. After that it is washed off in the same manner every day until it is perfectly well.

ANALYSIS OF CASES.

I have removed the appendages for bleeding fibroids of the uterus in 65 cases. These cases have all recovered from the operation. The history, subsequent to the operation of a large per cent. of these cases, I have been unable to trace.

Cases 26, 28, 47, 48, 55, 61, 64, or 14 per cent. continued to menstruate indefinitely after the operation. Their symptoms were so severe in 26, 47, 48, 55, or 6 per cent. of the whole number that hysterectomy was afterward employed. In none of these cases was hysterectomy found necessary because of increase of the growth of the tumor. In the remaining cases, so far as I have been able to trace them, the tumors have reduced in size, hemorrhage has ceased and the patients have been materially benefited while in a small per cent. actual symptomatic cures were obtained.

BASSINI'S OPERATION FOR INGUINAL HERNIA PUT TO THE CRUCIAL TEST.

BY E. J. SENN, M.D.

INSTRUCTOR IN SURGERY AND ASSISTANT TO THE CHAIR OF PRACTICE OF SURGERY, RUSH MEDICAL COLLEGE, CHICAGO.

The radical cure for inguinal hernia has been a problem which called forth the ingenuity of the surgeon from time immemorial up to the present day. The very fact that so many operations and varieties of technique have been devised, showed most positively that there was some fundamental principle at fault and every new operation or a modification was in the hope of correcting it.

Like all difficult topics in surgery which are to be solved, the error is made of delving in a world of intricacy and complexity for a difficult solution, when as a matter of fact a simple expedient is awaiting its discoverer under a misty cloud. Sims' speculum is a most excellent example, demonstrating what a wonderful scope of utility such a simple instrument fulfilled. Most elaborate instruments have been invented and every possible means imaginable promulgated for the disposal of the sac and the obliteration of the canal in hernia; but in each instance there was a great tendency for recurrence and consequently a great percentage of failures. These results were not due to a lack of the requisite instruments; but to a wrong principle as a working basis. Not until Bassini devised his operation for inguinal hernia, was the true defect overcome, namely, restoration of the obliquity of the inguinal canal. This operation has an anatomical surgical basis and marks an era in surgery. It seems incomprehensible that such a simple variation in technique from older procedures, should not have been resorted to earlier.

Professor Bassini of Padua first described his new method for the radical cure of inguinal hernia at a meeting of the Congress of Italian Surgeons held in March 1888. He reported 102 cases in which the operation was successful. At a later time he was able to present the following unprecedented statistics on cases upon which he operated himself or his colleagues.

Of a total of 251 cases, there was no return after a period varying from one to four and one-half years in 108 cases. In 131 cases there was no reappearance in periods varying from one month to two years. In four cases the result could not be ascertained and there was a recurrence in only seven cases. Such statistics from so reliable an authority should convince the most fastidious of the superiority of this operation over all others. Fortunately it is assuming its proper place in the minds of surgeons throughout the world and beyond doubt is the one which will hold prestige for all time. The operation is the one almost invariably selected in the surgical clinics of Rush Medical College and as yet I have heard of no relapses.

I wish to report the following case, as the operation was performed on a very unfavorable patient with a most excellent issue and which in my estimation is of more moment, as far as the reliability of Bassini's operation is concerned, than positive results in a hundred favorable patients.

F. J. N., German, age 67 years, consulted me Aug. 31, 1895, for double inguinal hernia of some thirty years standing. The hernia on the left side was small and gave rise to no inconvenience; but the one on the right side was as large as two fists when descended and caused considerable annoyance in spite of truss support. Upon examination I found a large internal ring, capable of admitting four fingers, in fact pressure atrophy of the truss had transformed an oblique into a direct hernia. Patient was in a bad physical condition, being of a very neurotic temperament; business reverses having brought on great despondency. Had multiple strictures in the deep urethra and both lobes of the prostate were enormously hypertrophied, necessitating daily catheterization. Urine ammoniacal and contained large quantities of albumin and casts. Arcus senilis well defined. In spite of contraindications, the patient was determined to risk an operation for the radical cure.

Operation: Patient was admitted into St. Joseph's Hospital and operation performed Sept. 1, 1895. Chloroform anesthesia owing to renal symptoms. Incision four inches in length, extending over the inguinal canal parallel with Poupart's ligament. The cord was isolated from the sac, and which was easily accomplished as there were few adhesions, although the patient wore a truss for many years. After enucleation the sac was incised and found to be empty. At the internal ring the sac was transfixed and ligated with catgut. To make sure double sure, another ligature was thrown around the sac, one-fourth inch higher up. The sac was then excised, the stump iodoformized and allowed to return. Four external silkworm sutures were then passed through the skin and Poupart's ligament on the one hand, then underneath the cord and through the conjoined tendon and outer border of the rectus muscle, aponeurosis of the external oblique and skin of the opposite side. These sutures were caught with forceps to be tied later on. The cord was next lifted from its bed with blunt hooks. The skin and aponeurosis of the external oblique at the edges of the wound were well retracted. The internal border of Poupart's ligament and the conjoined tendon were scarified with a point of a needle to a degree just short of causing capillary hemorrhage. The inguinal canal was then closed by uniting Poupart's ligament to the conjoined tendon and the external border of the rectus muscle with thirteen interrupted sutures of heavy chromicized catgut. Great stress was

laid on putting two reliable sutures at the internal opening without causing compression of the cord. The cord was next placed in its new canal and the aponeurosis of the external oblique stitched over it with fine catgut. The external silkworm sutures *in situ* were now drawn taut, tied and the operation completed with a superficial row of interrupted horse-hair sutures approximating the skin. In dressing the wound care was taken to elevate the scrotum well with adhesive strips. The wound was hermetically sealed with collodion dressing.

After Treatment: Some four hours after the operation, when the nurse had momentarily left the room, the patient arose from his bed, went to the closet and evacuated his bowels. It was impossible to keep him in bed thereafter, and he took his daily walks *ad libitum*. Knowing that the damage, if any, was already done, and as he was a private patient, restraint by force would have brought censure upon me by friends, I left him to his own discretion. There were no unfavorable symptoms: the highest temperature was 100.6 degrees, on the fourth day. The silkworm and horse-hair sutures were removed on the seventh day after operation. The patient was discharged from the hospital three weeks from the date of operation. Upon examination there was not the slightest impulse transmitted on coughing, and the canal was firmly closed throughout and remains so up to the present day.

Remarks: This case teaches us several important facts. In distressing cases of hernia, advanced age, even if accompanied with pathologic conditions, should not obviate the benefits derived from an operation for a radical cure. In this instance the operation selected, namely Bassini's, and which appears to be well nigh infallible, must be given its well-deserved merits. However, I wish to call attention to the modifications in technique which I employed. First, as regards the external silkworm sutures as tension sutures. Again, I took into consideration the age and other conditions present which had a very deteriorating effect on the tissues, and resorted to scarification of tendinous structures to induce a hyperemia and consequently increased tissue proliferation: although it is well known that connective tissues generally are the most proliferative of all tissues; especially is this the case with tendons. Often in hernia operations, where there are few adhesions to the sac, it is enucleated almost bloodlessly and extravasation is at a minimum. How illogical to bring such parts together for a permanent union without a raw surface! I think that the success in this case is largely due to this recourse. I do not think that the pillars would have held intact during the great strain exercised after operation before there was any chance for union; except for the great number of catgut sutures about one-fourth of an inch apart, as ordinarily but three to four sutures are deemed sufficient; also to the fact that there were four rows of interrupted sutures in all: by far more reliable than either mattress or continuous sutures. Bassini's operation has the advantage over all other operations in that the canal is changed into a curve instead of a straight line, consequently the greater resistance to a relapse. Bassini leaves his patients walk in a week or ten days after operation with no bad results; but even in a week's time the healing process has been well established: but when great force is exerted before any regeneration has taken place at all is a most excellent test.

THE ETIOLOGY, SYMPTOMS AND TREATMENT OF RHINOLITHS, WITH THE REPORT OF A CASE.

Read at the Annual Meeting of the American Laryngological, Rhinological and Otological Society, New York, April 17, 1896.

BY W. SCHEPPEGRELL, A.M., M.D.

CHAIRMAN OF THE SECTION ON OTOLGY, LARYNGOLOGY AND RHINOLOGY, LOUISIANA STATE MEDICAL SOCIETY; VICE-PRESIDENT NEW ORLEANS ELECTRIC SOCIETY; FELLOW OF THE SOCIÉTÉ FRANÇAISE D'OTOLOGIE ET DE RHINOLOGIE, ETC.

NEW ORLEANS.

Frances L., age 13 years, was brought to me by her mother, September, 1894, on account of a catarrhal discharge from the right nostril. She gave the following history:

About three years ago, without any cause which she could recall, the right nostril commenced to discharge as if from a continued cold. Soon afterward she became subject to headaches and felt as if she could not breathe, and could sleep only with her mouth open. A physician was called in, who took her temperature and, finding an elevation, pronounced it "malarial fever." She was given quinin and other remedies for malaria without success, there being always an elevation of temperature, varying from 99 to 101 degrees. Her breath was offensive and her appetite poor. After having tried antimalarial remedies and other treatments by several physicians, without any apparent improvement, the mother was advised by a friend to have the child examined by me as the symptoms from which she suffered might be due to "catarrh."

A rhinoscopic examination showed the left nostril stenosed by a deflected septum; the right nostril appeared atrophic, and on the floor of this nostril appeared a black mass, with an offensive odor, somewhat similar to the crusts so often found in ozena. An attempt to dislodge this mass by means of a silver probe, gave rise to a grating sound, and a diagnosis of rhinolith was made. After clearing the nostril by means of a nasal syringe, an attempt was made to remove the stone, but without success, as the anterior opening was not sufficiently large to permit the passage of the stone. A part of the calcareous mass was then broken off by means of strong forceps, and the rhinolith was then removed without much difficulty. The nostril had been anesthetized by a 10 per cent. solution of cocaine, and the child suffered but little during the extraction. The stone was found to weigh 24½ grains. The child was given an antiseptic nose wash, and the fever and headaches did not recur.

The specimen was sent to Dr. Metz, the city chemist, who made a careful analysis of it; he reported that the nucleus in this case was formed of a blood clot, the composition of which was still distinctly shown in a spectroscopic examination.

From the history of the case, we conclude that this rhinolith had developed about three years ago; as the blood clot, from some unexplained reason, had been surrounded by a precipitate of calcareous matter from the nasal secretion. This had increased in size until the case was called to my attention. The stone was so large that it had deflected the septum, causing considerable stenosis of the other nostril. The right nostril had been atrophied from the pressure of the rhinolith and from the irritation of the fetid secretion surrounding it. In the efforts to clear this nostril of its secretion, the nasal mucosa had been lacerated by the

sharp edges of the stone, giving rise to the absorption of septic material, and fever and headaches as the result.

Rhinoliths form an interesting part of the study of the diseases of the nose, not only on account of their rarity, but also on account of their uncertain etiology. The literature of these nasal concretions is, however, not new, as cases were already described in the 16th century by Mathias von Gardi (1502),¹ Bartolini (1654),² Clauder (1685),³ Dekerue, Vitus Reidlinus, Ruysch (1733),⁴ each of whom report isolated cases of rhinoliths. A collective study of this subject was not made until 1845, when Demarquay⁵ made an elaborate report of all the published cases.

Rhinoliths owe their origin to the presence in the nostril of a foreign body, around which the secretions of the nostril have gradually precipitated a calcareous mass. A piece of dry secretion may, however, form a nucleus or a clot of blood, as in the case here reported. In many cases the nucleus of a foreign body has been found; in most cases, however, the original body being soft has become absorbed by the surrounding mass, and the nucleus is then not found. In the present case, the nucleus was not clearly defined to the eye, and was ascertained only after a careful spectroscopic examination.

The body of rhinoliths are composed chiefly of inorganic matters (80 per cent.), especially of phosphate and carbonate of lime, carbonate of magnesia and some oxid of iron. They differ very much in size, sometimes being so small that it is surprising that they were not ejected from the nose during the process of blowing, and, at other times, so large that they fill the whole lumen of the nostril. In the case of Brown reported by Mackenzie,⁶ the rhinolith attained the enormous size of 4.44 by 2.5 by 1.2 c., and weighed 12.9 grams, and a case reported by Zuckerkandl⁷ was still larger.

The salts of which the rhinoliths are composed, derive their origin from the secretions of the nose. Why these concretions should form in certain cases and not in others, is not understood. Graefe⁸ and Sajous⁹ believe it to be due to a gouty diathesis, but this theory is not supported by the experience of other observers. Demarquay found this diathesis present in only one of fifteen cases which he examined. This writer suggests that the narrowing of the inferior meatus is the predisposing cause, and that the alterations of the secretions of the nose have some influence in their formation. The change in this secretion, however, is probably the result and not the cause of the rhinolith.

As the etiology of the majority of diseases are now supposed to be associated with some microorganism, observers are not wanting who have ascribed the development of these formations in the nose as due to microbial origin. Gerber¹⁰ reports a case in which he found a rhinolith made up of calcified microbes, and believes that these concretions are formed through the activity of these bacteria. E. J. Moure¹¹ in the *Mondsschrift für Ohrenheilkunde*, describes two interesting cases of rhinoliths, in which he was unable to account for the development of the rhinolith in the second case except on the microbial theory, as the rhinolith was filled with large masses of bacteria.

The symptoms of the presence of a rhinolith is usually a chronic discharge from the nostril, frequently of a fetid character, and sometimes reflex symptoms as headaches and neuralgia of one of the

various branches of the trigeminus. If the size of the stone is sufficiently large, nasal obstruction and its manifold effects are added as a prominent symptom. Although a smooth hard foreign body may remain in the nostril for a considerable time without giving rise to any special disturbance, still rhinoliths, on account of their rough and angular exterior, usually give rise to irritation and inflammation of the surrounding mucous membrane, and generally to a purulent discharge and to the development of granulation. The discharge may be retained on account of the foreign body interfering with free drainage of the nostril, so that the fetor in some of those is very offensive. Atrophy may also result, as in the case which I have reported. In some cases the symptoms are much more severe, as in a case reported by Hendley,¹² in which the nose was greatly swollen and a sinus opened externally, discharging pus. Bosworth¹³ quotes a case of Bovill,¹⁴ in which the left side of the face was swollen, there being also left facial paralysis, ptosis and epiphora of the left eye, and the nose and septum deviated to the right side, and the hard palate distorted.

The extraction of a rhinolith, when small, presents no special difficulty. The mucous membrane having been thoroughly cocaineized, the stone may be removed by means of a nasal scoop or a strong angular nasal forceps. Sometimes a snare may be successfully used for the extraction of the rhinolith, as first suggested by Voltolini,¹⁵ and the ordinary lithotrites used for urinary calculus sometimes facilitates the extraction. In the case described by Moure,¹¹ the body of the rhinolith was situated in the posterior part of the nostril, and it was removed by forcing it into the pharynx, whence the patient expectorated it from the mouth. Where this procedure is carried out, the soft palate should be held against the pharynx, with the finger of the left hand, so that the foreign body can not be swallowed, or fall into the larynx. When the rhinolith is too large for extraction, it should be broken up by means of a drill operated by the electro-motor, or strong forceps or the lithotrite, and the separate fragments extracted with forceps.

Bergeat¹⁶ describes a case in which he utilized the properties of hydrochloric acid in dissolving the earthy constituents of bone in the removal of a sequestrum from the nostril. He applied the acid by means of a sound with a spiral extremity, and repeated these applications until the sequestrum had been so diminished in size that it could be extracted without difficulty. Although I have not heard of anyone making use of this procedure in the case of rhinoliths too large for extraction, still the use of hydrochloric acid would no doubt be a useful expedient in certain cases.

SOCIETY PROCEEDINGS.

Chicago Pathological Society.

Regular Meeting, March 9, 1896.

DR. JAMES B. HERRICK, Vice president, in the Chair.

DR. JAMES B. HERRICK read a paper entitled "Two Cases of Pernicious Malaria." (See page 863.)

DR. H. B. STEHMAN read a paper entitled "Bovine Tuberculosis," and made some remarks upon tuberculin as used for diagnostic purposes in cattle. (See page 861.)

PRESENTATION OF CASES AND SPECIMENS.

DR. J. HOLINGER presented three cases of *cholesteatoma* of the ear, with specimens, and discussed them as follows:

Case 1.—Twenty years old, was operated upon in fall of 1893. He was treated in the Eye and Ear Infirmary for several months for suppuration of the right ear, the drum of which was vacant, and granulations were removed at several instances, yet the fetid discharge did not become less or thinner. The general condition was very poor. The boy was anemic. He was learning the trade of a plumber but could not work longer than an hour at a time, then became tired, dizzy and had to stop. Since the operation he works steady. The greatest improvement in his general condition was noticed soon after the operation, when two months after his discharge from the hospital his nurse did not recognize him. Now nothing of his anemia that he suffered with from childhood can be proved. His ear stopped discharging and there is only one small moist spot near the Eustachian tube, all the other very large cavity is covered with healthy, dry epidermis, and can be controlled through the external meatus. His hearing was, before the operation, zero for whisper and six feet for conversation. It is now three meters or ten feet for whisper.

Case 2.—Patient is 22 years old and was sick since his second year. After three weeks of observation, during which polypoid granulations, and finally the almost entirely loose hammer were removed, and regular syringing of the attic with Hartman's antrum tube did not have any effect whatever on the bad-smelling, thick secretion, which carried considerable masses of epidermoid scales: the operation was performed middle of December. The bone was eburneous, and granulated very slowly. Three weeks after operation the whole wound was covered with Thiersch's skin grafts. During a narcosis of bromid of ethyl Dr. Beard was kind enough to cut the flaps out of the patient's arm, while I removed the granulations from the bone and stopped the hemorrhage. After the patient had recovered from the narcotic the flaps were put in place. The greatest part of them took. I did not succeed, however, in covering the Eustachian tube, in consequence of which you see a small, red granulation in back of its opening, the only moist place in the whole cavity. Different experiences of several authors (Profs. Liebenmann, Bezold, Schwarze), as well as my own, convinced me long ago that the perpetual opening behind the ear is the only operation that is able to prevent these cavities from suppuration and necrotic process, with the final perforation into the skull and meningitis. In this patient the other ear shows a typical cholesteatoma with large scales. But there was never retention or decomposition of secretions or necrosis, therefore I did not operate there. The hearing distance on the operated ear was two feet for conversation, now it is one foot for whisper. The ear that was not operated upon was the better one before, and had a hearing distance of five feet for conversation.

Case 3.—Wm. M., 17 years, came to my observation in Post-Graduate Medical School two weeks ago. I removed a large polypoid granulation from the posterior upper margin of the drum, which was vacant with the exception of a narrow adhesion that connected the mallet to the anterior wall and the promontory. You see now the white epidermis distinctly descending the promontory. It is only the neighborhood of the Eustachian tube that it does not cover yet. There you find a few granulations. The other middle ear of the patient is entirely covered with epidermis, which you can see through a big perforation of the drum. The rest of this membrane you see in back and front of the displaced mallet. The hearing of both ears of this patient is very poor, only four feet for conversation. The specimens are temporal bones, for which I thank Dr. Hectoen. I performed there the regular Zaufal operation, as I did it in these cases. One shows the operation before its most dangerous step, the removal of the bridge between antrum, external meatus and middle ear. The other one after this, and opens a free view into the middle ear, attic with ossicles, antrum. In all cases of cholesteatoma, however, the conditions are not as clear ones as in the normal, and then you have to make your way without antrum in the hard bone, and

avoid the facial nerve, which takes often considerable knowledge of anatomy of temporal bone.

DR. L. L. McARTHUR. *Fibroid Tumor of the Scrotum.*

A patient came to my office not long ago with a tumor of the scrotum for the purpose of having it aspirated. Clinically, the tumor presented the conditions which obtain with a hydrocele. The tumor was firm, small above, large below, smooth in outline, and quite fairly elastic, yet harder than it seemed possible for a hydrocele to be. It was not translucent either to sunlight or the electric light; therefore I made a hypodermic puncture before resorting to aspiration, finding that the needle went into a solid growth. The patient was sent to the hospital for its removal, the nature of which could not be determined prior to operation. By manipulation it was free from the testicle and lying above it, extending from the external inguinal ring to the bottom of a rather large scrotum. The specimen has wasted about 25 per cent. in size through the influence of alcohol. The cord ran down on the inner aspect of the tumor. On cutting through the tissues of the scrotum as one does in hernia, the various layers were recognized, and it was seen to come down upon the peritoneum. On opening the peritoneum I found a hernial sac in which lay a tumor which had but one small adhesion on the inner aspect of the tumor: that is, the finger could be swept completely around the tumor except on the inner aspect as it lay in the scrotum, and the index finger could be readily carried through the inguinal ring into the abdominal cavity. There was no history of a change in size from position. There was no history of intestinal or mesenteric contents coming down into the hernial sac. On studying the adhesion which existed on the side of the growth mentioned, it was found to have, after cutting through the peritoneal wall which covered the tumor, a connection with the vas deferens as near as could be made out. The patient says that it was always larger than the opposite side, but that in the past nine months prior to operation, it had increased and become painful. As the tumor had somewhat the characteristics of a fibrosarcoma, it was decided to resect the vas deferens and remove that portion which was attached. This was done.

Microscopic examination of the growth proved it to be a fibroid tumor which seemed to start from the vas deferens and filled the hernial sac. It was a hernial content. The peritoneum was resected up around it, especially the part which folds around the testicle in its descent and makes the tunica. The patulous character of the inguinal canal made me believe it to be a congenital growth, and the continuation of the peritoneum with the bursa of the testis showed that that was probably true. A small portion of the peritoneal sac was ligated off to make a normal bursa over the testis. A ligature was applied to the distal end of the vas deferens to prevent the escape of seminal fluid. The patient made a good recovery.

2. *Cyst of the Appendix.*—The next case is one that occurred in the practice of Dr. Frankenthal, of this city, and a relative of his family. A young man of 25 had been having for three years repeated attacks of appendicitis which were typical in character, and were usually caused either by excesses or carelessness in the selection of diet. I was called twice during the past three years to see him on account of these attacks and advised non-operative interference because while the symptoms were fairly acute, they were not alarming. His temperature would range between 100 and 103; the pain was fairly well marked, and an elongated tumor could be distinctly felt. He recovered from his first attack and by being careful in his dietary had none for a year and a half. He had a second attack, after which he paid more attention to his diet and a long time elapsed before he had another attack. Finally, about six months ago, he had a third one, when it was decided to remove the appendix after all the inflammatory symptoms had subsided. Each attack was followed by a rise of temperature, the thermometer often indicating 103 with acceleration of the pulse and the formation of a tumor. In operating, much to my surprise, I found an elongated appendix, five inches in length, markedly distended. A tumor was to be felt before operation which seemed to run down into the pelvis, and it was about the size of an ordinary Frankfort sausage. It was firm, elastic and translucent. Its contents, when allowed to escape, consisted of clear, glairy mucus. It was simply a mucous cyst of the appendix. I present it to you, not that such cases have not been found before, for there have been some reported, yet they are not numerous, but because it seems almost inexplicable how he could have had a temperature as high as he did ranging over a period of ten days without any pus or suppurative process. I can not conceive of his having had a suppurative process in his appendix, and then having it disappear, leaving nothing but a clear mucus. There were no adhesions in this case. The appendix, which was elongated and hanging down in the pelvis, was movable in the

abdominal cavity and showed no attachments to either the mesentery or other intestines. Its neck was totally obliterated.

DR. LUDWIG HEKTOEN.—It will be remembered that Dr. Van Hook (*Medicine*, March, 1896) described a strangulated inguinal hernia of the vermiform appendix. In the literature he found twenty-nine cases of cystic dilatation of the vermiform appendix: to this number he adds his own case, an unpublished case of Treves and one that came under my observation, making the total number of cases thirty-two. This small number shows the comparative rarity of cystic appendix.

The pathological condition in Dr. McArthur's specimen, as well as in many other similar specimens, is undoubtedly a partial obliterating appendicitis with consecutive distension of the distal part by the accumulating products of the mucosa and the inflammatory exudation during recurrent attacks of appendicitis, the regional lymph glands being unable to absorb the contents of the cyst because of chronic indurative lymph-adenitis, or because the lymphatic vessels are constricted at the cicatricial closure of the appendiceal lumen, which point is well marked in Dr. McArthur's specimen by the circular constriction near the proximal cut end. This specimen, taken in conjunction with the clinical history, demonstrated conclusively that there may be a partial obliterating appendicitis with consecutive cystic dilatation of the appendix.

DR. E. R. LE COUNT—I would suggest as a possible explanation for the fluid in the cyst, that the obliteration not only affected the lumen, but that the inflammation shut off the blood vessels on the outside of the appendix, causing an edema of the tissues.

The Medical Association of Georgia.

Abstract of the Proceedings of the Forty-seventh Annual Meeting, held at Augusta, April 15, 16 and 17, 1896.

The Association met in the Richmond County Court House, and was called to order by the President, DR. FRANK M. RIDLEY, of La Grange.

The Address of Welcome was read by DR. EUGENE FOSTER, of Augusta, which was responded to by DR. E. R. ANTHONY, of Griffin.

PRESIDENT RIDLEY then delivered his annual address, in which he forcibly and eloquently dwelt upon several topics of interest to the profession.

The first paper read was by Dr. W. J. MATHEWS, of Middleton, entitled

THE TREATMENT OF PNEUMONIA.

The Doctor had never seen a case in his experience where he thought the symptoms warranted abortive treatment, owing to not seeing the patient until a few hours after the prodromic chill, the lung then being engorged to such an extent that he thought his efforts would prove futile. Having satisfied himself that he has a case of pneumonia to deal with, his first step is to make the patient comfortable. To meet this end he envelops the affected side with counter-irritation, preferably turpentine. To relieve restlessness, pyrexia and pain he gives phenacetin. Should phenacetin fail, he gives morphin hypodermically. To reduce hyperpyrexia he administers phenacetin in sufficient doses every three or four hours in connection with a stimulant, the purpose being to reduce the temperature to 101° or 102°. In his experience phenacetin does not, like some of the other coal tar products, depress the heart. He advocates the application of blisters. He had never seen a case calling for venesection. To control the pulse he gives veratrum viride every three or four hours with whisky. The overworked heart should be closely watched, its action sustained and clot prevented. This he does by digitalis and carbonate of ammonia. In the stage of resolution he resorts to supportive treatment. The type of which he had spoken was the acute lobar variety.

DR. J. W. DUNCAN, of Atlanta, seldom blisters an adult. In the very initial stage a blister might do some good. He does not give the coal tar preparations in pneumonia, for the reason that if they are given to reduce temperature they are liable to produce cyanosis. He frequently uses veratrum viride and considers it a sheet anchor in this disease.

DR. J. B. MORGAN, of Augusta, read a paper on

COLLES' FRACTURE.

The most common and frequent fracture with which the general practitioner had to do was a Colles' fracture. The diagnosis of this fracture was not difficult. The history of the accident, the characteristic deformity, pain and seat of the

lesion, point at once to the nature of the fracture. Every case of Colles' fracture can be readily reduced by strong, forced dorsal flexion. This is best done under an anesthetic. The best temporary permanent dressing is Wyeth's modification of Pilcher's. The plaster of paris dressing is an excellent one, and is to be preferred in old people where there is firm impaction which the surgeon does not care to break up, or in cases where the fragments are more or less comminuted. It should be applied from the lower border of the metacarpus to the middle third of the forearm, with the patient's hand in the straight position. A straight dorsal splint may also be employed, but it is not as desirable as the plaster of paris. Under no circumstances use the angular, crooked or pistol-shaped splint, and no form of splint should be allowed to project beyond the metacarpus. The fingers must remain freely movable to prevent stiffness of the joint. Limited motion should be encouraged at first; later active and free. In aged patients, where we have more or less impaction of the broken ends, reduction should not be attempted, [as it is better to have a crooked deformed wrist than a failure in bony union, and impaction favors the consolidation of the fractured bone.

DR. W. L. CHAMPION, of Atlanta, contributed a paper on

THE IMPORTANCE OF CAREFUL CHEMIC AND MICROSCOPIC EXAMINATION OF URINE IN APPLICANTS FOR LIFE INSURANCE.

Within the past few weeks the author had examined patients with kidney lesions, who a few days or weeks previously had applied for life insurance and had been recommended as good risks. Every medical examiner, after due deliberation, ought to be able, after making a thorough physical examination, having considered the applicant's predisposition to any disease, and last but not least, having made a thorough chemic and, if necessary, microscopic examination of the urine, to tell the life expectancy of the applicant before him. Cases were cited by the author to demonstrate that a great many practitioners are too prone to overlook the condition of the kidneys, not to make a careful and thorough examination of the urine, not only in examining applicants for insurance, but their desire to formulate a correct diagnosis in diseased conditions should make it so. He urged the extension of chemic and microscopic investigations in this line of work.

DR. A. W. STIRLING, of Atlanta, in the discussion called attention to some experiments which he had made some years ago, and which formed the basis of a graduation thesis to the University of Edinburgh. Chiefly through the observations of Pavy, Johnson and others it was becoming known that every phase of albuminuria was not a case of Bright's disease. In order to ascertain the actual number of persons in whom albuminuria was present in health, he examined 369 boys between the ages of 12 and 16, who belonged to one of the large training ships on the Thames, near London. In order not to make a mistake in regard to the presence of albumin, he examined each one with four different reagents. He found albumin most common three hours after the boys got out of bed and assumed the erect posture, when the percentage was by examination 20.8 per cent. Of the boys that played in a band the percentage of albumin was about 60 per cent., while in those that did not play in the band it was only 12.8 per cent. Mr. Stichel, of Paris, had seen blindness produced by the playing of wind instruments due, he says, to passive cerebral congestion with a similar condition of the retina and choroid.

Dr. Stirling says that the urine is usually found to be absolutely free from albumin while the patient remains in bed and it makes its appearance within a variable but generally short time after the assumption of the erect posture, and independently of food and all other conditions. The albumin continues in the urine for only an hour or two, or perhaps in varying quantity throughout the day, but as a rule it is disappearing in the afternoon, and is entirely gone by bedtime. The ingestion of food has little effect in producing the albumin, and it is not breakfast which causes its frequency of appearance in the morning. Sometimes he had seen a slight rise after a meal, but this is trivial and by no means constant. He had boys brought ashore to the infirmary and confined to bed and then albumin was absent from the urine until they got up, breakfast or other meals having no effect. He had made very many and various experiments in connection with this subject, all tending to prove the same thing.

He examined 92 other cases, whose ages varied from 5 to 94, with the result that there was an increase in the percentage of people having albuminuria with advancing years. From 20 to 30 years he found the percentage of albumin to be only 10 per cent.; 30 to 40, 25 per cent.; 40 to 50, 36.4 per cent.; 50 to 60, 66.6 per cent.; 60 to 70, 75 per cent.; 70 to 80, 75 per cent.; 80 to 90, 83 per cent. These observations were confirmed by Grainger Stewart.

With regard to the advisability of insuring cases of "cyclic" albuminuria, he would suggest that in the present state of our knowledge, the most satisfactory method of dealing would be for the companies to accept an apparently healthy albuminuric at a high premium, agreeing to rearrange this on their being satisfied of the disappearance of the albumin for such a length of time as would give reasonable expectation of this being permanent.

THE MODERN TREATMENT OF SKIN DISEASES.

DR. BERNARD WOLFF, of Atlanta, read a paper on this subject, in which he outlined in a succinct manner the progress that has been made in the province of dermatology within the last twenty years. The remedies selected for use in cases of disease of the skin can be employed in several ways, namely, lotions or washes, ointments, pastes, plasters and soaks, as well as baths. Baths are of two kinds, the vapor and the simple medicated bath made to resemble the natural mineral waters. The chief purpose of the bath is, besides cleanliness, to bring about healthy activity of the skin, to remove scales, soften infiltrated areas, increase the elimination of waste products through the skin and to relieve irritable conditions of the skin. Baths are especially valuable in the treatment of parasitic and syphilitic affections of the skin. Ointments and pastes are more frequently used than any form of preparation in the therapy of skin diseases. The base of an ointment is a matter of importance, for upon it largely depends the benefit to be derived from the medicament. Formerly only lard and wax were used; now we have a greater number of articles to choose from. Of these vaselin, lanolin, adeps lanæ, and resorbin are the most useful. Ledermann has introduced a new excipient called resorbin. It is composed of refined almond oil, emulsified with distilled water with the addition of a small quantity of yellow wax and lanolin. The author's experience with casein ointment leads him to regard it as being incompatible with too many substances to be of much practical value.

The use of soaps is of some importance in the treatment of diseases of the skin. Only neutral soaps, or those containing an excess of unsaponified fat, are to be recommended. Free alkali is destructive to the protective horny layer of the skin. The over-fatty soaps make commendable vehicles for various medicaments, the most frequently used of which are hydro-naphthol, resorcin, sulphur, tar, corrosive sublimate. The use of soaps has the effect of encouraging cleanliness on the part of the patient, and cleanliness is one of the prerequisites of successful treatment.

The removal by electrolysis of nevi, moles, warts, and small malignant new growths of the skin is a well established surgical procedure.

DR. M. B. HUTCHINS, of Atlanta, said the modern treatment of skin diseases should embrace internal as well as local or external treatment. The patient's constitution should not be overlooked, although if he had to choose between local and internal treatment, he should prefer the former in the treatment of 99 per cent. of the cases of affections of the skin. He had not given the plaster mulls of Unna much trial. They had been objected to on account of containing a gutta percha base, and in any event the dermatologist would have to carefully select the cases in which to use them. With reference to soaps, such as the bichlorid of mercury, the chemic change which takes place renders the remedy inert, and it is impossible to get any absorption through the unbroken epidermis. Success in the treatment of syphilis by mercurial inunctions is attained, not by the absorption of the mercury through the skin, but by inhalation of the vapors from the mercurial ointment.

As regards gelatin paste he had used it a little, but thought it was objectionable because it stuck to everything with which it came in contact, particularly woolen goods.

In some cases of acne on the faces of young ladies he had obtained beneficial results by using the constant galvanic current to the cheeks where the eruption appeared. The stimulating action which takes place encourages the glands to throw off secretions without allowing them to remain sluggish and thus block up the follicles of the skin.

APPENDICITIS.

A paper on this subject was read by DR. SAMUEL LLOYD, of New York City. It was largely statistical. In making his compilation the author began with the very earliest recorded cases, and it covers a greater number of medical than surgical cases. The total number examined up to April 5, 1896, was 558, and the result was that 263 recovered, and 295 died. Of this number 226 were operated upon, 192 recovered, and 31 died. On the other hand, in direct contrast to this, 265 cases were treated conservatively, 60 recovered, while 205 died. A case was cited which the author had seen in consultation.

illustrating the course of extraperitoneal abscesses. According to the table of cases that the author had examined, the pathologic conditions could be summed up, as follows:

1. Cases in which the disease follows traumatism.
2. Cases following septic inflammations in other parts of the body, such as salpingitis in the female, post-partum septic inflammation of the uterus, typhoid fever, tuberculosis.
3. Direct infection of the mucous membrane of the appendix by its contained bacteria.
4. Alterations in its position and shape so as to occlude its lumen, preventing the escape of its natural secretions and contained intestinal contents.
5. Changes in its position and pressure upon its mesentery by growths, or impacted feces in the cecum.
6. Alterations in its position or shape so as to shut off its blood supply.
7. Foreign bodies, including fecal concretions.

There was one other pathologic condition about which the author could obtain no information from the cases tabulated, namely, the "abdominal tonsil," referred to by Sutherland, Robinson, Yeo Burney, Haigh, and Bland Sutton.

It is probable that in the present state of surgical knowledge the majority of medical men are in favor of surgical intervention in cases tending toward general peritonitis, even though the symptoms do not point to perforation, or abscess formation, in the hope that drainage of the abdominal cavity and the removal of the focus of disease may enable the surgeon to forestall what would otherwise be a fatal complication.

Of 445 cases out of 558 that were examined, 79 per cent. resulted in abscess, perforation, peritonitis, etc.

The following table gives the full data:

Perforation, without given cause.	11
With abscess.	10
With ulceration.	16
With peritonitis.	32
With concretion or foreign body.	41
With gangrene.	7
With gangrene and concretion.	19
With inflammation.	13
With hardened feces.	1
With concretion and peritonitis.	24
With foreign body and peritonitis.	7

It will be noticed that this is a dismal showing for the conservative treatment of appendicitis. The author believes that no case of appendicitis should be considered as purely medical. When one is called to a patient it is his duty to immediately prepare for operative interference. He would advise operation in every case, after studying the subject carefully, where the symptoms showed any tendency to increase. If a tumor was present and the symptoms suggested the possibility of the presence of pus, he would surely operate.

Dr. E. H. RICHARDSON, of Atlanta, followed with a paper on THE MEDICAL SIDE OF APPENDICITIS.

He cited the opinions of eminent practitioners both in this country and Europe in favor of non operative interference in a large proportion of cases.

Dr. W. H. ELLIOTT, of Savannah, said the foremost difficulty in cases of appendicitis was to know *when* and *when not* to cut. No man was fit to treat appendicitis who was not absolutely willing at any moment that he might be needed to open the abdominal cavity.

Dr. WILLIS F. WESTMORELAND, of Atlanta, was quite sure that in every case of relapsing appendicitis he had seen there were adhesions from previous attacks. Some of these cases had died. If they had been operated on in the primary attack, the chances would have been better for their recovery. He would open the abdomen as soon as appendicitis was diagnosed, if the patient would permit it.

Dr. JAMES A. WRIGHT, of Augusta, considered the opera-

tion for this disease very difficult, for the reason that no two cases were alike. It was an easy matter to cut down, but if pus and adhesions were found around the appendix the operation was extremely difficult.

Dr. J. W. DUNCAN, of Atlanta, had seen and treated medicinally several cases of appendicitis during thirty years' practice, one of them having died from a recurrent attack a few months after the primary one. He was satisfied that many cases operated upon were nothing but typhoid fever, and that other cases thought to be typhoid fever were really appendicitis.

Dr. J. B. S. HOLMES, of Atlanta, considers the disease a surgical one, and thinks it is safer to operate as soon as a diagnosis is made. The only cases he had lost were those that had been treated medicinally from two to four days previous to operative interference. If an early operation is performed, the mortality should be small.

Dr. WM. H. DOUGHTY, of Augusta, maintained that it was not prudent to operate upon every case of the disease as soon as the diagnosis was made, for the reason that the surgeon does not always see the cases in their incipency. If he did, it would be safe to remove the appendix as the chances were that at this time there would not be pus formation; in other words, the surgeon would have a comparatively clean condition within the abdominal cavity, and the mortality of operations done under these circumstances ought to be small.

Dr. M. L. BOYD, of Savannah, took the position that if all cases could be diagnosed early, it would be wise to operate at once.

Dr. GEORGE H. NOBLE, of Atlanta, thought it was extremely unfortunate that the general practitioner should view appendicitis from a prejudiced standpoint. There were undoubtedly, many cases of the catarrhal form that were relieved temporarily, or cured by purgation, possibly permanently. Where we have rupture and the discharge of the contents of the appendix into the peritoneal cavity, we have the fulminant form of the disease, and in such cases very prompt and active measures must be instituted. He advocated early operation.

Dr. L. G. HARDMAN, of Harmony Grove, said that while there were cases of appendicitis calling for the services of the surgeon, there were others that could be treated successfully by medicinal measures. Of fifteen cases which had come under his care, only two were operated upon. All recovered, both the operative and non-operative cases. In the cases operated on suppuration had occurred, and one of the patients, a physician, was present.

SOME ALBUMINURIC COMPLICATIONS OF PREGNANCY.

A paper on this subject was read by Dr. HOWARD J. WILLIAMS, of Macon. He said this complication was present in from 6 to 50 per cent. of all pregnancies. On the other hand, puerperal eclampsia was comparatively rare. From Jan. 1, 1891, to March 31, 1896, he had encountered 10 cases of albuminuria or toxemia in 163 pregnancies, and 2 cases of eclampsia in this number—10 cases. This gives 6 per cent. of toxemia and about 1 per cent. for eclampsia. The percentage given is based upon accurate analyses of the urine of every woman he had attended during the time mentioned. Albuminuria may be present in varying degrees, from a mere trace to a very large per cent., the urea and other excreta accumulating in the blood in the same proportion. The toxemia is slow or rapid, according to the degree of retention of the latter from the outside. These variations were shown by the recital of three cases.

The cardinal indications are to promote elimination of the toxic materials circulating in the blood and to restore the excretory organs to their normal functions. If, however, the poisoning is excessive and the life of the mother and the fetus is at stake, then the indication is to promptly empty the uterus.

Elimination is preëminently indicated for all forms of kidney disease, and in this complication it yields the best results. But if it can not be tolerated, or disagrees, a more liberal diet should be given, such as the white meats of fowls, fish, oysters, fresh fruits, and nutritious breads. Remedies to promote elimination by the kidneys were then dwelt upon. Nervous excitement should be controlled by sedatives and narcotics, though not to the extent of interfering with eliminative measures. Elimination of the waste products having failed to restore the functions of the excretory organs and the condition is urgent, eclampsia being imminent or other complications alarming, the uterus should then be emptied.

Dr. R. B. BARRON, of Macon, delivered the

ORATOR'S ADDRESS.

He dwelt upon and pleaded for higher medical education. Relative to practicing medicine purely for money, he said that money with the true physician was of secondary consideration;

that the real incentive for the best work with those practitioners who achieve success was that broad humanitarianism which impelled with resistless force the commissioned agents of God Almighty to relieve suffering, to stay the pangs of agonizing pain, to fight to the bitter end humanity's implacable and unconquerable enemy—death—regardless of any other consideration.

THE AFTER-TREATMENT OF TRACHEOTOMY CASES OF MEMBRANOUS CROUP

Was the title of a paper read by Dr. R. M. HARRIS, of Rome, in which he drew the following conclusions:

1. Croup, whether diphtheritic or membranous, is almost invariably fatal without surgical treatment, and the few cases that recover by medicinal treatment alone are not to be considered.

2. So far as the practical indications for tracheotomy are concerned it makes no difference whether croup be diphtheritic or membranous.

3. Tracheotomy has the advantage over intubation, in that it gives a better means of expectorating the membranes and furnishes free drainage from the site of septic infection.

4. Tracheotomy is a justifiable surgical procedure and should be performed in all cases where our therapeutic resources have been exhausted, and where the patient is in imminent danger of suffocation. It should be done in hopeless cases, since it either offers a chance for the patient or promotes euthanasia.

5. Tracheotomy keeps the patient alive until the pseudo-membrane disintegrates and resolves into a muco-purulent liquid and is expectorated through the tube.

6. The after-treatment is the most important part of the procedure and the author attributes the successful results reported to the persistent use of lime water.

Dr. J. B. S. HOLMES, of Atlanta, reported several interesting surgical cases.

Dr. GEORGE H. NOBLE, of Atlanta, reported a case of ENORMOUS VENTRAL HERNIA CURED BY A PLASTIC OR FLAP OPERATION.

The subject was a very large woman who came to him from a neighboring State, giving a meagre history, saying that the protrusion first appeared after severe straining, and grew rapidly until it reached the size of an adult head. The treatment she had received consisted in local applications only, no attempt at operative measures having been made. The case is of considerable interest on account of such a large hernia in this region and because the expansion of the ribs prevented closure of the ring by approximation of its margins, necessitating therefore a plastic or flap operation to close the aperture which was large enough to pass a closed hand through without resistance.

The operation consisted of 1, in trimming away the excess of the sac and uniting the peritoneum with buried catgut sutures; 2, four strong tension sutures were passed through the abdominal walls, piercing the semilunar lines down to the peritoneum, but not implicating it; 3, the semilunar flap was carefully outlined upon either side over the recti muscles with a straight or vertical side upon their outer margins and the convex borders turned toward and extending to the hernial ring. The aponeurosis of the external oblique and the outer layer of that belonging to the internal oblique muscles were cut through and the flaps liberated except where their bases joined the ring and turned over the opening, accurately abutting the edges, in which position they were stitched with buried silk sutures. The convex borders coincided with the margins of the ring to which they were made fast; 4, the recti muscles were brought in direct apposition by surrounding them with the large catgut, thus adding another layer of strong tissue over the hernial opening; 5, the skin and fatty tissue were then brought together and the tension sutures tied over all, the wound dressed antiseptically, with firm pad, roller bandages, etc. The wound proved entirely aseptic, and the result was very gratifying.

In another such case the writer would use buried silver sutures instead of absorbable material.

Dr. M. B. HUTCHINS, of Atlanta, read a paper on the

TREATMENT OF SKIN DISFIGUREMENTS BY ELECTROLYSIS.

That electrolysis has a wide application and a legitimate use, he was convinced by his own experience during the past five or six years. To do the work outlined in the paper a few galvanic cells, a sponge electrode, a needle holder, and for accurate work, a milliampèremeter, are necessary. In most cases the needle should be attached to the negative pole. The current used is weak, and varies from three to seven or eight cells. With a milliampèremeter it is found that we get from 1 to 5

milliampères from this current to the relative position of the electrodes, the greater amount of intervening tissue reducing the current by resistance, a lesser interval increasing it. The number of needles used, the manner of grasping the sponge electrode, the dampness of the sponge, all influence the strength of the current. The strength of current used in these operations is harmless to the patient and would not be felt upon the unbroken epidermis.

For the removal of superfluous hairs on the face of ladies, electrolysis was the only method. Many of the patent hair removers were excellent stimulants to its growth. A lounge, good eyes, a good light, a steady hand and perseverance were necessary. Dr. Hutchins had never seen any injury result from the treatment of moles by electrolysis. He had removed one by excision which had become epitheliomatous through a razor cut. There was no recurrence. Moles with hairs in them will frequently disappear from the simple effect of the current used in destroying the hairs, but destroying the mole does not always destroy its hair as they are deeper.

Warts of various kinds, so tedious of treatment with the old methods, save that of excision, with or without canterization, usually dissolve into froth under the action of electrolysis, being more easily destroyed than the average mole. The author then dwelt upon electrolysis in the treatment of epithelioma, small fibromata, milia, sebaceous cysts, keloids and hypertrophic scars, comedones, angiokeratoma, etc.

The paper was based entirely upon the author's own practical experience, and his implicit faith in this method of treatment is due both to results in practice and upon himself.

Dr. M. L. BOYD, of Savannah, followed with a report of a few interesting surgical and gynecological cases.

Dr. DUNBAR ROY, of Atlanta, Ga., read a paper on

THE USE OF SUBCONJUNCTIVAL INJECTIONS OF MERCURY IN CERTAIN FORMS OF EYE DISEASES.

In this paper the author tabulated twenty-five cases of various eye affections, and his experience leads him to the following conclusions: 1. In infected processes of the cornea, ulcers, abscesses, wounds, etc., this method of treatment is quicker and therefore more satisfactory for clinical purposes than those usually employed. 2. In acute iritis it does not seem to exert any beneficial influence, but produces great pain, while in other cases the pain is mitigated. 3. In chronic iritis and iridocyclitis the pain and congestion are often markedly influenced for the better, but it has no effect whatever upon adhesions of the iris to the capsule of the lens. 4. In post-operative infection and panophthalmitis it is by far the best method to which we may resort for good results. 5. In pannus of the cornea absolutely no effect was produced one way or the other. 6. With lesions of the choroid and other deeper structures of the eye he had had no experience, but expects to try this method whenever a case presents itself. From his personal experience he would unhesitatingly say that we can depend upon subconjunctival treatment alone, but as an adjuvant it is most excellent and in some cases produces results far more beneficial than were expected.

Dr. A. W. STIRLING, of Atlanta, read a paper on

GLAUCOMA IN RELATION TO GENERAL PRACTICE.

He said that glaucoma was to the ophthalmic specialist one of the most interesting of diseases, comprising 1 per cent. of all ophthalmic troubles. While he believes that every case of the disease requires the most skillful advice that can be obtained, still it is the first and foremost affection which comes within the province of the general practitioner, and with him lies frequently the ultimate safety or destruction of the eye involved. The reader reported several interesting cases, after which he dwelt upon the variability in tension. Coming to the treatment he counseled against the indiscriminate use of mydriatics, especially atropin, scopolamin and cocain in affections of the eye. Glaucoma had often resulted from the use of these agents and is almost always accentuated by them. In most ocular diseases they are harmful, and the general practitioner would do well to remove them from his list in ophthalmic practice, except when he knows he is dealing with an uncomplicated keratitis or an inflammation of the iris. On the other hand, in myotics, and notably in eserine and pilocarpin, we have a fairly certain means of temporarily benefiting many cases of glaucoma and of saving valuable time till the most suitable method of treatment can be decided on.

The following officers were elected:

President Dr. Geo. H. Noble, Atlanta.

First Vice-President Dr. J. B. Morgan, Augusta.

Second Vice-President Dr. R. B. Barron, Macon.

Secretary—Dr. R. H. Taylor, Griffin.

Treasurer, Dr. E. C. Goodrich, Augusta.

Place of meeting, Macon, Ga., 1897.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:

Per Annum, in Advance \$5.00
Single Copies 10 Cents.

Subscriptions may begin at any time and be sent to

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 86 FIFTH AVENUE, CHICAGO, ILLINOIS.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Henry P. Newman, Venetian Building, Chicago, Ill., sending him a certificate or statement that the applicant is in good standing in his own Society, signed by the President and Secretary of said Society. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership.

On receipt of the subscription the weekly JOURNAL of the Association will be forwarded regularly.

Gentlemen already members of the Association should send their annual subscription to the Treasurer, or direct to the JOURNAL office.

All communications and manuscript of whatever character, intended for publication in the JOURNAL, should be addressed to the Editor, and all communications relative to the business of the JOURNAL, proof sheets returned, or in regard to subscriptions, should be addressed to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, 86 Fifth Avenue, Chicago.

Original communications are only received with the understanding that they are exclusively contributed to this JOURNAL.

SATURDAY, MAY 2, 1896.

THE CERTIFICATE PLAN.

In order to avail themselves of the excursion rates, those purchasing tickets must obtain from the railway agent at the starting point a certificate that full fare has been paid by the purchaser from the starting point to the place of meeting. On arrival at the place of meeting, this certificate is handed to the registration committee. (This year a separate envelope has been provided.) The Secretary will then sign the certificate, and return it through the post-office to the member. This signed certificate, presented to the agent at the place of meeting when returning will enable the purchaser to secure a return ticket for one-third fare.

THE NEWEST PHRENOLOGY.

There has been lately organized in connection with an eastern university a society the members of which agree to give their brains to be examined after death for the furtherance of scientific knowledge. The Anthropometric Society organized a few years ago has similar provisions for its membership, and it is expected that some valuable results may be obtained in time from this special and rather peculiar line of research. It goes without saying that the examination of the brains will be made by acknowledged experts and with every possible precaution and appliance to insure that in every minute particular it will be fully up to the most recent data of our knowledge of the subject, of cerebral anatomy and physiology. This, however, is not all that is needed; pathology without clinical observation is robbed of more than half its value, and

in these cases, every phase and fact of character, education and career of the original owners of the brains should be studied and correlated with the findings. With distinguished individuals who are more or less public property during their lives and with public characters generally, these desiderata may be met to a greater or less extent, according to their prominence and the interest taken by their fellows in their doings; but how about the less conspicuous individuals? If the brain structure, both macroscopic and microscopic, is to become so well known that we can determine what convolitional arrangements are normal or in the line of progressive evolution, or, on the other hand, are degenerative stigmata, we may expect some rather astounding revelations. In our present data we have already some rather remarkable facts; while CUVIER and CROMWELL had the largest brains, GAMBETTA had one of the smallest, and in two eminent men whose brains were recently reported upon by DR. BURT G. WILDER there was nothing found that would correspond particularly with their intellectual preëminence during life. In one, indeed, the brain was almost abnormally simple in its arrangement and moreover revealed one or two peculiarities that are at least eccentric and hardly indicative of superiority according to our present light on the subject. It would not be agreeable to friends, or to one's own post-mortem vanity if such can be assumed, to find an idiotic simplicity of gyri or the criminal frontal convolitional type of BENEDIKT. It can hardly be expected, however, if brain examinations become general that such possibilities can be insured against.

The physical examination, moreover, of the subjects whose brains are to be examined should be most thorough and by those who are competent to judge of all possible defects or conditions that can have a bearing upon brain development. This is a condition that can not be always fully met under the circumstances, and might be objectionable to some, but the difficulties it presents are light as compared to those of the mental and moral scrutiny that would be desirable.

With all these difficulties, however, the movement is a good one and we hope that it may extend. It can not fail to bring out many facts of value and it should not be embarrassed by any sentimentalism. It will, if extensively followed, throw most valuable direct and side lights on a vast number of medical anthropologic and psychologic questions. It should be supplemented by a more general and thorough study of the character peculiarities and physical stigmata of criminals and defective individuals, whose brains should also be submitted to the same complete examinations by experts. In connection with a thorough system of child study in public institutions, the examination of immature brains when practicable would be a most valuable adjunct. From all sources

combined we might reasonably expect to obtain most valuable additions to our knowledge of cerebral physiology.

THE ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Ordinarily we have no sympathy with attempts to establish any more national medical associations. The scope of the AMERICAN MEDICAL ASSOCIATION is wide enough to embrace every branch of medical science, however special its character or object, and this particularly so since the greater prominence and importance given to sectional work in this body. The AMERICAN MEDICAL ASSOCIATION, indeed, has become what the Congress of American Physicians and Surgeons sought to be, a veritable confederation of medical bodies devoted to independent lines of thought and practice, meeting in joint session in recognition of the common ground on which they all stood. In fact, the several sections of the AMERICAN MEDICAL ASSOCIATION can more justly claim a national representative character than the constituent bodies of the Congress, since the latter have an arbitrary limitation of membership as to numbers and to a certain extent locality. Of course, any number of men devoted to the special study and practice of any department of medicine have the right to associate themselves for social or scientific purposes and to limit the number and select the particular individuals with whom they prefer such association, but this does not give them the right to arrogate a specific national representative character or designation, since there is an unavoidable inferential reflection upon the professional standing of the men of the same category who do not happen to belong to their especial coterie. These have, in reality, a club rather than an association character.

The sections of the AMERICAN MEDICAL ASSOCIATION are attempting to do more than the special organizations referred to and though exception may be taken to the lack of special professional qualifications for membership in each, that is a matter to be attended to in their future development, until it shall come to be that the enrolled members of the Section on Surgery, for example, shall be recognized surgeons, those of the Section on State Medicine, men actively interested in national, State and municipal sanitation, and those of Obstetrics and Diseases of Women, authorities upon the various conditions pertaining to the sexual life of woman.

The Association of Military Surgeons of the United States, however, with the American Public Health Association, is not amenable to criticism as a superfluous body. It is true that the latter is not properly a medical body at all, although the great majority of its members and those of especial authority in its councils are medical men. The Association of Military Surgeons is in a measure also extra-medical in this,

that its members are military as well as medical men, they are officers as well as physicians, their bigamous relations, however, involving dual rather than divided obligations. While, perhaps, all that is strictly professional in the duties of the medical officers of the army, navy and national guard or volunteer militia, ought to be familiar to every thoroughly educated graduate in medicine, the peculiar requirements of a military and naval career—in the limitation of the authority of the medical officer and of any strictly personal interest in the cases that come under his care, in the predominance of the sanitary functions of his office, in the minimizing of supplies, remedies and apparatus to the utmost, in the necessity for the prompt suggestion and application of substitutes and temporary expedients, in the frequent changes of locality and exposure to danger; these and innumerable other conditions combine to impair the efficiency of the man who is unused to sword as well as scalpel.

The Association of Military Surgeons proposes to establish closer bonds between the medical officers of the national service and those of the national guard and volunteer militia of the several States, with the object of harmonizing their methods of procedure and making perfect concert of action between them possible should another great necessity occur for their conjoint operation. The officers of the army and navy recognize the benefit to themselves of the inter-communication afforded by the Association, as is evident from the numbers who are already enrolled as members.

The subjects to be considered at the approaching meeting of the Association in Philadelphia, May 12-14, immediately after the adjournment of the AMERICAN MEDICAL ASSOCIATION, are an earnest of the strictly special, that is medico-military, direction in which the Association proposes to work, to-wit, on standards of physical efficiency; visual acuity of recruits; value of athletics in the training of soldiers; baths, bathing and swimming for soldiers and sailors; practicable plans of sanitary organization and sanitary field service in our own and foreign armies; emergency rations; methods of sewerage of camps, posts, etc.; effects of new ordnance and projectiles in field service; care and transportation of the wounded on the field and aboard ship; annual encampments, etc. Add to these, which refer to *terra firma*, the changed conditions and requirements pertaining to military life on the deep sea in a floating box, hermetically sealed, and it will be admitted that the Association will not lack topics for its annual reunions.

There are certain obstacles yet in the way of the high professional prestige at which this Association aims. The national guard in many of the States and especially its medical department, lack that rigid system of organization which must obtain in any disciplined military establishment. There must be a

strict examination into professional competency, as in the United States Army, United States Navy and United States Marine Hospital Service, before any young medical officer should receive a commission; and promotion to the higher grades should depend upon the length of and the faithful performance of duty. It should not be possible for a governor's wife to persuade her husband to appoint her favorite medical adviser Surgeon General of the State, with the control and direction of the medical department of the national guard of that State, although not having the slightest aptitude or professional qualification or official experience. Perhaps in no better way can reform in the organization of the medical departments of the several States be accomplished than through this very Association, whose existence shall have been more than justified should it succeed in this direction.

CRIME AND THE NEWSPAPERS.

It is well known that the newspapers have a sensible effect, not in causing crime, but in producing those emotions, in recording the movement that leads to crime. It is a curious subject;¹ but considering the rising flood of sensational sheets, it may not be amiss to discuss it in a general way. In some minds the story of a crime excites a powerful tumult.² As regards the newspapers, the effect of the story is more pronounced than if it were played, or read, let us say from Victor Hugo, because the newspapers, with a felicity of which they have the secret, present exactly those details of a crime that most strongly influence the feelings. As far as the papers are concerned the rationale of crime is this: The emotion excited in B's mind by reading of A's crime, impels B to commit a crime similar to A's. That such cases occur we know from unquestioned testimony. Various morbid passions are at work here and that tendency to imitate what is admirable (whether rightly or wrongly conceived), is universal in human nature. "By a noble prerogative of our nature," says DE LA PLACE, "the story of great and virtuous actions inflames us with a desire to imitate them. But there are some persons who, from their organization or from pernicious examples, have acquired disastrous inclinations, which are violently excited by the narrative of a criminal action that has become the object of public interest. From this point of view, the publication of crime is not without danger."

It is certain that this tendency to imitation is over-

poweringly strong in neurotic subjects where impulses are not under sufficient control, either from the deliberate conviction that to obey one's impulse is a sort of religion or, at least, the only rule of conduct that a sensible man would observe;³ a belief held by the late PAUL VERLAINE and the disciples of the Decadent school, or in that unhappy and not insignificant class in whom the impulse to commit a crime is not so much a matter of imitation, as an obsession,⁴ dominating the thought, and sometimes beyond the power of the will to subdue.

Murder is a crime peculiarly liable to be a matter of impulse and imitation. How often it is committed by the victims of the mental *bouleversement* above referred to, may be seen by a glance at the literature of this subject. There is a fact reported by SAMPSON.⁵ "It was stated by MR. EWART in the House of Commons, upon the most unquestioned authority, that out of 167 persons who had been executed during a certain period, 104 had been present at executions. The mental process that takes place in the minds of criminals at the spectacle of an execution is well illustrated by a case of DESPINE'S. In this instance, decapitation seemed too puerile a thing to turn a man from a course of crime.⁶ The "thrill" of emotion experienced by the humane witness of an execution by decapitation is thus described by BYRON:⁷ "The first (beheading) turned me quite hot and thirsty, and made me shake so that I could hardly hold the opera glass (I was close, but was determined to see, as one should see everything, once, with attention); the second and third (which shows how deadfully soon things become indifferent), I am ashamed to say, had no effect on me as a horror, though I would have saved them if I could."

In the classical case of WILHEMINA STROHM fully described by PROFESSOR HOPF,⁸ we get an instance of the full effect and sequel of these emotions in a neurotic respect. As this case displays in a very striking manner the anatomy of a morbid criminal obsession, we shall give some details. There is no essential difference, as far as the *effect* goes, between witnessing an execution and reading about one in the papers. The spectacle of an execution makes such an impression on this girl, that the idea that she must end her life in so "beautiful" and "public" a manner takes complete possession of her mind. In her own words: "the pomp of the military escort, accompanying the prisoner to his doom, the crowd of spectators, the pity which, despite the atrocity of the crime,

² De la Place: Essai philosophique sur les probabilités, p. 209. This is a passage from Le Grand du Sault: "On ne saurait croire combien les récits dramatiques et lugubres frappent les esprits faibles ou les individus prédisposés à la folie. Cette clinique journalière de crimes de l'aliénation mentale, du suicide et des exécutions judiciaires, qui malheureusement s'introduit de plus en plus dans les habitudes du journalisme parisien, a des conséquences vraiment fâcheuses pour le goût public, la morale, le repos et la santé des populations," *supra* p. 13.

³ A number of well known criminals have expressed this belief in their writings. See: Rapport médico-légal sur l'état mental de Lucien Morisset, inculpé de vol et d'assassinat par les Drs. Danner et Le Grand du Sault, Ann. d'hygiène. 3e Série, vi, p. 342. Other examples may be found in *Ibid.* p. 484. Kraft-Ebling: Vierteljahrssch. für ger. Med. Op. cit. shone in many eyes, the firm bearing of the culprit, his speech to the people, his subsequent confession to the priest of The Eternal, the rapid and dreadful incident of hanging," etc., was all profoundly felt, and it proved sufficient to turn an excitable head, in search of notoriety. She commits murder in the excitement brought on by the tumult of such thoughts.

Other cases of this kind, of more recent occurrence, have been collected by DESPINE,⁸ PAUL AUBRY,⁹ LE GRAND DU SAULLE,¹⁰ and others. In these the influence of the newspapers is very apparent. They must accept a certain amount of responsibility here. What was formerly furnished as an incentive and stimulus to perverted minds, by the naïf customs of ancient executions, is now supplied by the details and illustrations in the daily papers. We are given the most minute descriptions of the *vie intime* of criminals, their appearance, dress, political and religious ideas, their presents of flowers, reception of sympathetic friends, their "remarks" on various matters of public interest, prison life, bearing in court, etc., with lastly, the lugubrious and emotionally written incidents of their sentence and execution. All this is diffusely printed, widely circulated, greedily read and discussed. It is, therefore, not in the least surprising, (knowing as we do how the morbid criminal obsession is awakened) that in countries where the newspapers are particularly sensational, France, for instance, and the United States, serious crimes; such as murder and arson, crimes which it is certain, are liable to be epidemic at times among the depraved and degenerate, have grown enormously in number of late. It has been shown that in France the serious crimes have increased since 1826, 150 per cent.¹¹ An increase of alarming extent has been observed too, in Germany, Italy and England.¹² In the United States, murders, according the best statistics we have, those published by the *Chicago Tribune*, have increased from 1,808 in 1885 to 10,500 in 1895!

It is not a pleasing prospect that these figures afford. What makes matters worse, is the fact that the great publicity given to crime has an educational value for criminals, enabling them to accumulate experience, observe how particular crimes failed and why, and avoid similar pitfalls. That criminals analyze the the cases of noted villains, and profit by such study, we know from their own written testimony, which may be accepted, especially if it is like the following: "I studied," says MORISSET,¹³ "theft and its consequences, crime and its effects; and, well I observed this fact, that theft can be discovered in the actions of the majority of men. Does not the pimp profit by the labor of workingmen? Does not the merchant grow rich on the aptitudes of his employees?"

This passage is extremely characteristic.¹⁴ Criminals are often strangely impressed by the example of great villains. MORISSET thus wrote of the murderer LACENNAIRE: "L. is a splendid man, a powerful personality. His work leads to inferences of enormous importance. If I was, in theory at least, superior as a man of action, LACENNAIRE was incomparably stronger."¹⁵ etc. LE GRAND DU SAULLE, who examined MORISSET, ascribes the utter absence of the moral sense revealed in these passages, to the influence of literature. In these cases there is abundant evidence to show that the tendency to imitation, which in many is morbid, is purely the result of calculation, in which it would be difficult to find any traces of insanity. But we find certain traces of moral contagion, a perversion of which the above citations are singularly good examples, a contagion disseminated largely by means of the papers. "The rôle of the press in the spread of this contagion," says PROFESSOR LACASSAGNE,¹⁶ "is no longer deniable. Without going back to the woman, LOMBARDI, to MORISSET, to TROPPEMANN and to CORNIER, the recent attempt upon JULES FERRY is the most remarkable example; the previous excitations of the press fall like poisonous seeds upon an especially prepared soil." To the influence of this contagion he attributes the growing number of murders by *dépêchage*, or dismemberment, which, he says, have become the fashion.¹⁷ "The diffusion of the press, transmitting everywhere with an unparalleled precision and minuteness, the romances of the courts, the deeds and sayings of great criminals, becomes thus a school of exposition for weak and vacillating spirits, seeking with hesitation the method of committing a crime that has proved most successful." We have, in this country, reached the highest point of this contagion in the example of HOLMES, whose case is too notorious to need any further mention.

We must leave the subject here hoping, however, that some day, in response to public opinion, a remedy may be given for a disquieting state of things. Nobody would deny that the press is, on the whole, a beneficent institution. No one, we suppose, would wish to control its freedom. Yet, if it could confine itself to the barest account of a crime, being content to state the facts and nothing else, it would be free from an influence that does it little credit, and that its better members are not slow in censuring.

EMBARRASSING DEFECTS IN ENGLISH SANITARY ADMINISTRATION.

The sources of official responsibility among sanitary officers are twofold and often-times inharmonious. At the present time mistrust and discontent are rife in the medical branch of sanitary service. A scandal

has recently sprung up in the heart of London in consequence of which a number of officers became involved in charges of corrupt dealings with real-estate agents. The *Press and Circular* alludes to these troubles in an editorial, offering as a solution of many of the regnant difficulties that the Medical Officer of Health be given the power of appointment and control of all his subordinate inspectors. It further says: "Of late years London has been making great strides in the onward march of preventive medicine, a fact upon which the inhabitants of the greatest and richest city in the world may well be congratulated. In various ways, however, the metropolis is a laggard in the scientific race, and compares unfavorably with many provincial towns, such as, for instance, Newcastle and Glasgow. There can be little doubt that the lack of intelligent public interest has lain at the root of this lamentable backwardness in a matter so deeply affecting the welfare of the community as the administration of sanitary affairs. Until recently Londoners have been content to leave the management of their roads, of their water supply, of their sanitation, of their poor-law service, in the hand of local bodies, which were only too often corrupt nests of nepotism and jobbery. With the advent of the London County Council, however, and an awakening of general interest in municipal matters, the promise of a purer and a fairer future was gladly welcomed by the sanitary reformer. But the day of full salvation is not yet with us. In many of our metropolitan districts, rich and poor alike, the Vestrymen or Councillors are chosen by small hole and corner cliques, and are elected as local rulers and administrators of vast sums of money without even the formality of a public election. For such a travesty of representative local government the citizens have themselves to thank. The voters hold the key to the situation, and if they choose to organize their ranks, nothing would be easier than to return to the Vestries men of good standing and unblemished character, in whose hands the public weal would oust all mere party purposes and the sordid filching and diversion of the ratepayers' money, which is, perhaps, best described by the terse and expressive term jobbery. Turning to details of practical health work, we are at once struck with the importance of the sanitary inspector, who is, as it were, the policeman of preventive medicine. As the servant, first of the medical officer and then of the Vestry or Council, it is his duty to investigate and to report upon the multifarious details that are brought within the purview of local health committees. Sanitary inspectors as a whole, we are glad to believe, constitute an honorable and useful body of public servants. On the other hand, it is a matter of common knowledge that a certain number of them are unfit for their position, and may be regarded as inheriting the traditions of the

bad old days of vestrydom. But apart from the black sheep, it may be fairly questioned whether the whole position taken up by the sanitary inspectors does not require serious consideration. The claims of these subordinate officials, as it would appear from a perusal of the reports of their association meetings, have grown until the Liliputian body imagines itself nothing less than a giant of Brobdignag. The sanitary inspector, as pictured by the association, is in future to become a kind of inspector, lawyer, medical officer of health, doctor and engineer, who is to act under and report to the Vestry; to carry on his own scientific investigations; to be his own hygienic law-giver." To conclude and to "put the matter in a nutshell," it is that the choice and control of his subordinate sanitary inspectors should be centered absolutely in the Medical Officer of Health. Past experience has proved over and over again that of all men the sanitary inspector is least fitted to serve two masters.

A MUCH-NEEDED REFORM BEGUN.

Elsewhere in this issue of the JOURNAL will be found the details of a case of murderous malpractice by a midwife which has led to action by the Illinois State Board of Health that promises quite far-reaching results and a much-needed reform in the practice of midwifery, at least in large cities.

The case was made the basis of an appeal to the State Board by the Acting Commissioner of Health of Chicago, DR. F. W. REILLY, who also submitted therewith the following preamble and rules and regulations:

WHEREAS, The act constituting the State Board of Health of the State of Illinois, in force July 1, 1877, charges the Board with "the general supervision of the interests of the health and life of the citizens of the State," and empowers it with "authority to make such rules and regulations . . . as it may from time to time deem necessary for the preservation or improvement of the public health;" and

WHEREAS, The unregulated practice of midwifery, which allows midwives to prescribe for the serious illness of the lying-in, to apply instruments, to perform grave operations and to assume the conduct of other than cases of natural labor, results in a great and avoidable increase in the mortality of mothers and the newly born, to the detriment and injury of the health and life of the citizens of the State;

Therefore, The Board, in regular quarterly meeting assembled in the city of Chicago, does, this twenty-eighth day of April, A. D., 1896, hereby adopt and promulgate the following rules and regulations for the practice of midwifery by midwives licensed in accordance with the Act to regulate the Practice of Medicine in the State of Illinois, in force July 1, 1887, to wit:

Rule 1. A midwife, licensed by the certificate of the State Board of Health, is authorized and empowered to attend cases of natural labor only, and no other; and, after such labor, to attend the mother and child—all such attendance to be under such rules and regulations and medical control or supervision as may be prescribed by the health authorities of the city, town or village in which the midwife resides or practices.

Rule 2. Before such rules and regulations shall be valid and in force they shall be submitted to the State Board of Health for approval; and upon such approval, and their due publication to those interested, they shall have the same force and effect as other rules and regulations of this Board.

Rule 3. Due publication of said rules and regulations shall consist in furnishing one printed copy thereof, by mail or otherwise, to each registered midwife in the respective city, town or village.

Rule 4. Any act of practice—as by prescribing drugs and medicines other than the simple aperients, cathartics and diuretics, or the administration of anesthetics, or the application or use of instruments—in violation of the rules and regulations herein provided for, shall be held to be the unauthorized practice of medicine and surgery as defined in Section 10 of the Medical Practice Act of 1887, and the offender shall be liable to the penalties prescribed in Sec. 12 of said Act.

These rules and regulations were unanimously adopted, and it now remains for each municipality in the State to prescribe such restrictions through its health authorities as may best meet the individual conditions of midwifery practice in the respective localities; these, when approved by the State Board, will have the force and effect of law.

If these regulations shall succeed in limiting the practice of midwives in Chicago to their attendance, practically as midwifery nurses, upon cases of natural labor only—anything further to be referred at once to the medical practitioner—there can not fail to result a material reduction in the puerperal mortality of that city. The action would seem to be a short-cut and a practical one to the end aimed at for years in England, where, according to the London *Lancet*, the second reading of the Midwives' Bill in Parliament is fixed for May 6, but, as the *Lancet* confesses, with the very smallest chance of being enacted. There are, in fact, not one, but several bills in different stages of forwardness in that country, varying from one for the registration of existing midwives and women who have had a certain amount of training—which registration would confer the right to attend cases of other than natural labor—to “A Bill for the Prevention of Puerperal Fever” and others, which would limit the midwife to such attendance as is contemplated in the rules and regulations of the State Board of Health above given.
